frozen, but one where white men may live and work in comfort and with efficiency. The whole history of American experience with Alaska has proved that abundant return for wise investment may be expected. In Europe railways stretch far north of the latitude of Dawson, Fairbanks, and Nome, and this month the International Congress of Geologists is being royally entertained at Stockholm, but a trifle farther south than is Cordova, Alaska. It is true, as Mr. Brooks carefully points out, that railways to the interior of Alaska would need to look to the mines for tonnage, but this could be done with every prospect that in time agricultural communities would spring up in the region made accessible.

The most important railway now under construction is the Copper River & Northwestern, a standard-gauge line extending north over a hundred miles from Cordova. It is expected that it will be completed to the Chitina by November. From there to Fairbanks the distance is 240 miles but immediate construction is not anticipated. The Copper River & Northwestern is the road financed by the Morgan-Guggenheim syndicate primarily to reach the Bonanza copper mine. Incidentally some work has been done on a short branch to connect with the Bering River coalfield. A large amount of money has been spent on the enterprise. So far private capital alone has been drawn on. As an investment the road cannot be considered as other than doubtful since it is a large enterprise to be dependent upon a single mine. The proposal to take it over and extend it to the Yukon valley as a national project has much to commend it despite popular suspicion. Alaska is now in much the same condition as were the Western States and Territories before the trans-continental lines were built. When the Union Pacific was extended west from Council Bluffs it was not on the basis of freight earnings, but as a national defense against possible disunion, and to secure development of the public domain. That it made money incidentally was a fortunate though unexpected outcome. General Grenville M. Dodge, the chief engineer, has told how, when there was an effort to make a showing for the possible commercial success of the line, he had to figure in all the trans-Pacific as well as trans-continental traffic that existed and charge 'all the traffic would bear,' and even then was forced to make large drafts on his imagination. Today no one doubts the wisdom of building that road and with the accumulated experience of the years and the present higher standards of public conduct it should be possible to build railways in Alaska on terms fair both to the public and to private interests. Whether it be done by concession, contract, or by direct government construction, is a minor matter provided that the arrangement be honest and fair. The general concensus of opinion seems to be that in the Philippines American Government officials have worked out and applied a feasible plan, and it ought not be impossible to do here at home among our own people, what has been done half way around the world in a district inhabited by those whose interests and habits of thought differ so strongly from our own. The Copper River & Northwestern railway is only mentioned here as an illustration. There are other lines and other routes and the best should be selected. It would seem wise, however, to attempt first to complete what has been largely done by some private company, provided a satisfactory agreement be reached. In any event Americans should frankly face the fact that provision of railways to interior Alaska is a National duty. It is as much a Government function to build a railway as a wagon-road. The latter, however well it be made, must inevitably be incomparably less efficient. It has never been required that wagon-roads be assured in advance of enough traffic to pay interest and sinking funds on the investment. Why then should railways? The question becomes especially pertinent in the particular case under consideration. A rich and prosperous Alaska will be worth more to the Nation than several dreadnaughts — and will cost less. Mining men have a special interest in the matter since the first development in the country must be that of the values concentrated in the ore deposits. They have also a special responsibility since they, as a class, know Alaska best. It is time that they made their influence felt. We have no sympathy with the idea that Conservation necessarily means cold storage any more than that anti-social exploitation is the only form of development. Between the two is a mean that is just and reasonable and it should be the part of practical statesmanship to guide the Nation along that path.

Viva Mexico!

"*Viva la Independencia! Viva Mexico!*" Thus exclaimed Miguel Hidalgo y Costilla on the night of September 15, 1810, and the echo of that famous *grito* has sounded across the century which has intervened. Again on the night of September 15, 1910, it will be repeated with redoubled force by a nation which has witnessed the fruition of independence and has felt the material blessings that it brings. On September 16 the Mexican people will hold up for the adulation of the world a list of noble heroes, Hidalgo, Morelos, Matamoras, Rayón (patriot, metallurgist, and journalist), Mier y Terán, Guerrero, Felix Fernandez, in whom the celestial patron of the Revolution is honored in the name of Guadalupe Victoria, which he assumed as conquering soldier and as first President of the Republic. We need not pry curiously into the occult to explain the part which a reverent faith in the power of *Nuestra Senora de Guadalupe* played in achieving the freedom of Mexico. The virgin of Tepeyac stood for the fiat of heaven upon the new order of liberty and spiritual equality, superseding the old régime of mental and bodily bondage. She was the protectress of the down-trodden Indian, confessed as their loving mother in a hundred miracles; and when Hidalgo flung the banner of Guadalupe to the breeze he also flung in that same act the religious fervor of a whole race, with its dogged will and fatalistic contempt of death, against the waning strength of Spain.

Mexico is also celebrating the crowning glory of

her first century of autonomy in honoring Porfirio Diaz. It is a matter of simple coincidence that his birthday falls on the day of the *grito*, not a subtle political convenience as was the shifting birth-date of the great Napoleon, but it is a happy juncture. It throws into more prominent relief the merit of the man who made a unified nation out of warring factions. What he has done the world knows; how it might have been done differently is useless speculation; how it might have been done better is material for closet philosophers to demonstrate for the entertainment of the idle; several gentlemen, possessed of more daring than statesmanship, had the same opportunity as Diaz, and they failed. The time, the place, and the man, for the peace and prosperity of Mexico, is a trinity that came into conjunction when the great pacifier first assumed the reins of authority in 1880. A country that had never enjoyed financial credit has been lifted by him to so high a level that her securities passed the recent financial throes with no more than a momentary depression, in which the bonds of even the lending nations participated. Her industries have been developed under enlightened policies that are eclectic but not imitative. Her tariff is protective in principal, but liberal to the needs of consumers, while at the same time it is less fiscal in purpose than our own, or that of Germany or of France. Her mines have been favored in the past by laws admitting duty-free the initial plant required, and by a system of claim-tenure which renders it impossible to hinder legitimate enterprise by maintaining unproductive possession, except at large expense. It is an accentuation of the ancient law that has filtered down from Chaldaean sources, making use of the supreme test of right. Foreign capital has been welcomed, protected, and accorded advantages which have even caused the native-born Mexican to feel at times that a discrimination were made against him. Railroads have been built and administered under a system which we might wisely emulate. The problem of their nationalization has been solved without resort to absolute ownership, and the roads are responsible, through the need of maintaining a market for their bonds, to the bourses of the world instead of to a government bureau. Thus public administration and economical efficiency in operation are combined. In the face of powerful opposition by what we are now accustomed to call 'special interests,' Mexico delivered herself from the humiliation of bondage to speculators in silver, by stabilizing exchange, and leaving the manipulators in Paris, Bombay, and Shanghai, to buy her white metal as an article of simple merchandise. The monetary glamor was extinguished, and though many mine owners lamented the days when they could pay their labor in the depreciated product of their *haciendas* under a system of free coinage, the result has been to stimulate the development of other ores and to greatly diversify the mineral output of the Republic. From the days of thrilling romance when bandits waylaid *conductas* in the Sierras, Mexico has come to a condition of peace and safety, facilitating intercourse and mutual trust, without which the conveniences of a broad banking system could not have been realized. Thus the conduct of business has been facilitated, and the waste of a fluctuating currency eliminated, by the sound policies introduced through the efforts of the great financial minister, José Ives Limantour, whom Diaz had the discrimination to select.

Well may Mexico celebrate the establishment and guarantees of present peace, along with the homage which she pays to the liberators who fought and died for her freedom! Well may she honor the fame of her living statesmen who shed lustre upon the memories of those who are dead and gone! It is our fortune to join, as do all the nations of the earth, in honoring the heroes of Mexico. Her independence has lessened our own political difficulties. The importance to us, as a matter of international security, that there should be a Mexico for the Mexicans, was seen when Secretary Seward sent a curt message by a rough soldier to the gentleman from Austria. But let us not flatter ourselves, in joining heart and hand in these Mexican centennial festivities, that we are celebrating an echo of our own Glorious Fourth of 1776. The separation of Spanish America from the Mother Country received less stimulus than is commonly believed from our defiance of George III. Henry Clay's speech on the Panama Congress would have been so misunderstood as to excite a smile among the dons of Mexico and Lima and Buenos Aires. The Latin American uprising was part of a quite independent course of political evolution. Fundamentally the line of cleavage between Anglo-Saxon and Latin reconstructionists follows the divergent attitudes of the two peoples toward authority. The Spanish American considers the 'supreme government' as supreme; the constitution appeals less to his regard. The Anglo-Saxon touches his constitution with reverent hands, but makes short shrift of assumptions of absolutism in the executive (with due apologies to Mr. Roosevelt). The Colonial Congress passed the Declaration of Independence and fought it out, despite changing fortunes of war, to the end; the Mexicans were true to their traditions in the '*Plan de Iguala*,' which recognized the sovereignty of Fernando VII if resident in Mexico. It was a case of hair-splitting to ease the political conscience, no doubt, but it was effective, and in principle as far as the antipodes from the document signed by the patriots of seventy-six. The northern colonists had been fed on the doctrines of Pym and others of like ways of thinking, while Latin America had listened to the philosophy of the Abbé Raynal, and to the subsequent 'Rights of Man.' In their own way they won the liberties of their choice; they have suffered from dictator to dictator, as distinguished from our trials with the bosses who hold in their hands the will of the triumphant majority. In the end they have found stable political life under the unvanquished Porfirio. He has gathered about him able men who stand sponsors for that stability, Enrique Creel, José Ives Limantour, Olegario Molina, and their colleagues; and, on this festal occasion, we greet them and the nation they love and serve, with '*Viva la Independencia*!' *All's well with Mexico*!

Concentration at Cananea, Mexico

By Courtenay De Kalb

A distinguishing feature of the mill-work at the concentrator of the Cananea Consolidated Copper Co. is the close watch maintained upon efficiency obtained at every stage of the process. There is no working in the dark. The duty of every machine is a matter of record, and its maximum output is known through special tests upon each grade of ore subject to treatment. The mill has been frequently described, but it is constantly undergoing alteration in order to increase the percentage of saving. The following description represents the plant as it was in the month of April, 1910. The mill is in duplicate sections, each of which has a nominal capacity of 700 tons daily of a mixture of the Cananea ores, but when treating talcose ores from the Oversight mine the duty of each section is 900 tons per diem. The ore will be followed through the mill, so that the account here given will in effect be a flow-sheet, with details of results obtained.

Cananea Concentrator.

The ore from the crushing plant is received in six steel bins of 467 tons capacity each. The ore has been crushed to pass a 1-in. ring. It is delivered from these bins to conveyor F by six automatic pan-feeders. The conveyor, which is the standard Robins equipment, is 450 ft. long, and is of 16-in., 4 and 6-ply conveyor belting. It runs at a speed of 235 ft. per minute, with an inclination of 18° from the horizontal, and has a life of over 36 months, transporting 1400 tons of ore per day. The driving of this conveyor requires 10 hp. The belt delivers its ore to conveyor G, also a standard Robins, 16 in., 375 ft. long, driven at a speed of 335 ft. per minute, consuming 11 hp. Its life is 48 months, handling 1400 tons daily. Conveyor H, 115 ft. long, 16 in. wide, running at a speed of 216 ft. per minute on a grade of 10°, takes 700 tons of ore per diem from conveyor G to section D of the mill. It requires 3 hp., and the belt lasts 55 months. Conveyor I, 163 ft. long, 16 in. wide, 18° from the horizontal, inclined in the reverse direction to belts F and G, delivers its load at a speed of 235 ft. per min. to conveyor G. A 400-ton overflow-bin, held for emergencies, delivers ore to conveyor G by means of conveyor I. Conveyors G and H are operated by independent motors.

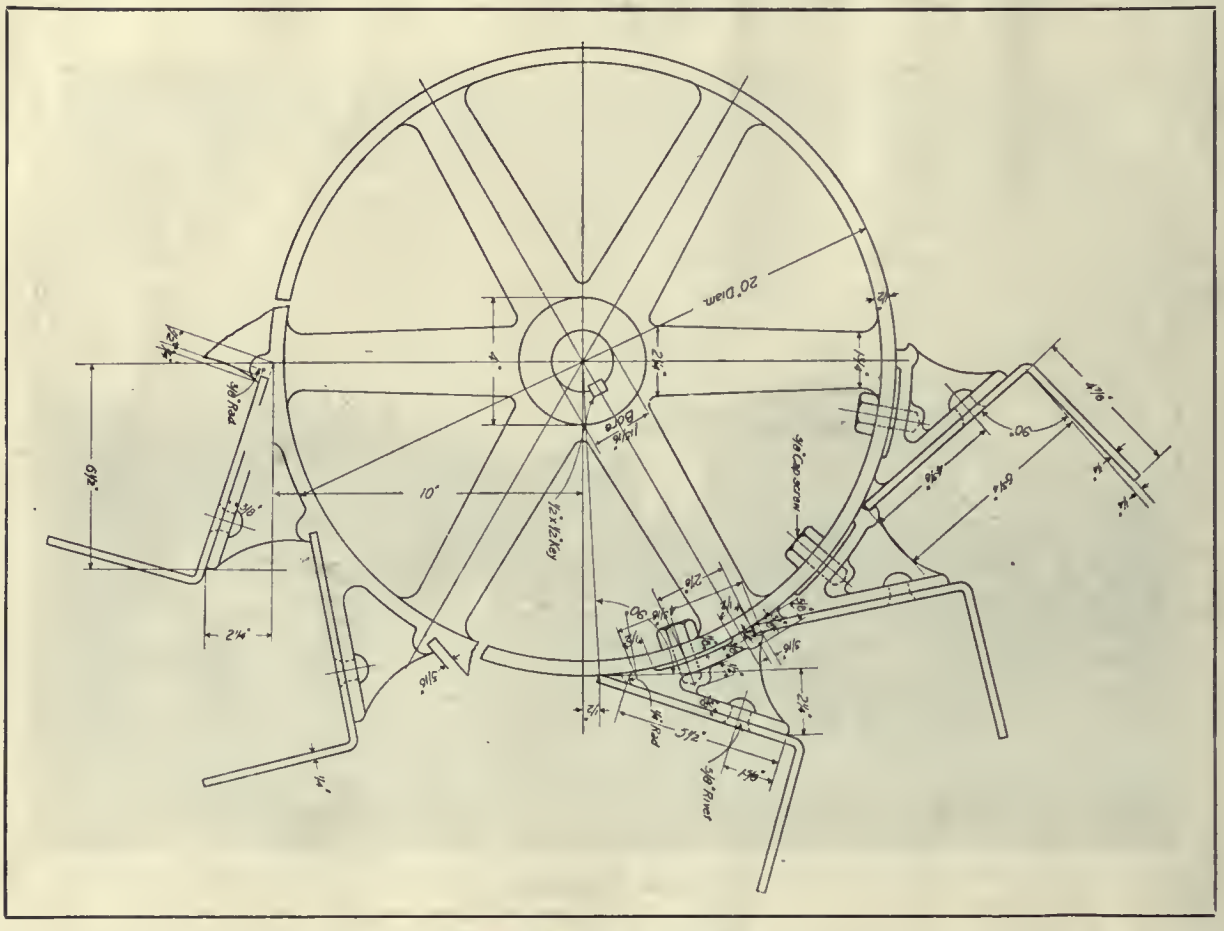
The analysis of the average ore-feed, made on samples taken by an automatic sampler over the fine-ore bins, shows, copper 2.88%, insoluble 64.8, iron (Fe) 11.2, sulphur 12, silver 0.4 oz. per ton, gold trace. The screen analysis of the feed to one section of the mill is as follows:

	Weight Per cent.	Tons Per day.	Copper Per cent.	Copper Tons.
On ⅝-in. trommel	24.0	168.0	2.76	4.637
On ⅜-in. trommel	11.0	77.0	1.76	1.355
On 3/16-in. trommel	11.5	80.5	2.00	1.610
On 2-mm. trommel	8.8	61.6	2.50	1.540
Through 2-mm. trommel...	44.7	312.9	3.53	11.045
Total	100.0	700.0	2.88	20.177

The ore at this point is discharged from the conveyors, and water is added, carrying it to two ⅝-in. trommels. These are 48 by 60 in., passing 700 tons of mill-feed per 24 hours, with the addition of 108 gal. of water per minute. The oversize produced is 24%, or 168 tons, which goes to the 'bull-jigs.' The 532 tons of undersize goes to the ⅜-in. trommel,

The latter is set with an inclination of ¾ in. per foot, and makes 16 rev. per min. It is built of four pieces of punched steel sheet, $^{5}/_{16}$ in. thick, with ⅝-in. round holes, spaced 1 in. centre to centre, rolled lengthwise to a diameter of 48 in. The average life of the screen is 30 days, doing a duty of 0.1 lb. of screen worn out per ton of ore passed.

The two bull-jigs, handling 168 tons of oversize, have a screen 24 by 40 in. of No. 12 wire. The plunger is 21 by 40 in., making 115 two and one-half-inch strokes per minute, consuming 2 hp. The screens weigh 21 lb. each, and last 80 days. The depth of bed maintained is 8 in. There is added 96 gal. per min. of water to each plunger. The performance is as follows: from 168 tons of feed, containing 2.76% Cu, is obtained 33.704 tons of concentrate with 5.32% Cu, leaving 134.296 tons of tailing assaying 2.28% Cu, the jig extraction therefore being 38.66%, and the concentration ratio 4.984 into 1.



Shovel Wheel for Jig Tailing.

The bull-jig tailing is de-watered by a Cole shovel-wheel, the construction of which is shown in the accompanying illustration. It consists of a series of shovels attached to the rim of a spoke-wheel, the spokes radiating from an inclined spindle. The wheel is 24 in. diam., weighs 113 lb., and has a life of 36 months. The wheel is of brass, but the 12 shovels are of 1¼-in. scrap-steel plate, and last 30 days. The de-watered tailing is sent to coarse rolls, 16 by 36 in., Allis-Chalmers class B, set to crush to ½-in. requiring 11 hp. The capacity is 132 tons of tailing per 24 hr., with an addition of 45 gal. of water per minute. The shells are made of Midvale steel and weigh 2860 lb., having a duty of 0.156 lb. steel per ton of ore crushed, the life being therefore 150 days. The screen analysis of the crushed product is: on ⅜-in. screen, 39.9% with 2.64% Cu; on $^{3}/_{16}$-in., 34 with 1.6 Cu; on 2-mm., 12.7 with 2 Cu; and finer than 2-mm., 13.4% assaying 1.85% Cu. This material is elevated by a belt-driven elevator, having 104 ft. of 18 in., 3-ply belting, carrying 50 elevator buckets, 16 by 8 in. each; the belt making 460 ft. per min. The belt lasts twenty months, and the buckets two months. The discharge is into two ⅜-in. trommels, 48 in. diam., set at an inclination of ¾ in. per foot, making 16 rev. per min. The trommels are in two sections, of two pieces each, made of ¼-in. steel, 76 by 32 in., with ⅜-in. round holes spaced ¾ in. apart, without margin. These handle all the undersize from the ⅝-in. trommel and the jig-tailing, making a total of 656 tons. The oversize, or 136.6 tons, goes to two 1-compartment Harz jigs, the jig-feed containing 2.31% Cu. These jigs are identical with the bull-jigs, but are driven at the rate of 130 strokes per minute. The ratio of concentration is 8.942 into 1, making 15.275 tons of concentrate assaying 5.82% Cu, the extraction being 30.39%, leaving 121.32 tons of tailing with a tenor of 1.68% Cu. The hutch-product is re-combined with the tailing, and this is all de-watered with a Cole shovel-wheel. Of this amount 119 tons are shoveled to fine rolls, Allis-Chalmers class B, set to crush to ¼ in. At this point 45 gal. of water per minute is added.

An elevator delivers this product to a ⅜-in. trommel. The entire 121 tons is obliged to pass this

screen. This is followed by two $^3/_{16}$-in. trommels, handling 651.021 tons in 24 hr. with an addition of 32 gal. of wash-water. These trommels, 48 in. diam., are of steel screen, in four pieces, of a total weight of 280 lb. The screen is round-punched No. 10 sheet, with $^3/_{16}$-in. holes spaced $^3/_8$-in. centre to centre with a 1-in. margin on the sides. The inclination is ¾ in. per foot, and the speed is 16 rev. per min. The oversize goes to two intermediate jigs, with 23½ by 35½-in., No. 4-mesh, brass screens, made of No. 12 wire, weighing 18 lb., and lasting fifty days. The plunger is 21 by 36 in., making 165 strokes of 1-in. length, and consuming 1 hp. The feed-water to the jigs is 70 gal. per min. The feed contains 1.79% Cu. The concentration ratio of 9.02 into 1 gives a smelter-product of 20.07 tons with 5.72% Cu. The extraction at this stage is 35.36%, leaving 161.02 tons of tailing with a copper content of 1.3%. The hutch-product in this case is part of the concentrate. The tailing is sent to another shovel-wheel which delivers its de-watered product to Bryan mills.

Up to this point there has been abstracted from the pulp-stream 33.704 tons of first jig concentrate, 15.275 of second jig concentrate, and 181.097 tons of intermediate jig-feed. The remaining 469.924 tons are sized through four 2-mm. trommels, giving 101.65 tons of oversize, containing 2.217% Cu, and 368.274 tons of undersize which is sent to Richards 'goggin type' hydraulic classifiers. The jigging at this stage is done on three double 2-compartment Harz jigs, producing 22.097 tons of hutch and pocket concentrate with a tenor of 5.74% Cu, and 79.553 tons of tailing holding 1.24% Cu, the concentration ratio being 4.6 into 1, and the extraction 56.25%. These jigs are provided with 23½ by 35½ in. No. 5-mesh brass screens made of No. 14 wire, weighing 14 lb. each, and lasting 40 days. The plunger is 21 by 35 in., making 170 strokes, 1 in. long, per minute, and requiring 1 hp. The tailing is sent to the shovel-wheel for the Bryan re-grinding mills.

The hydraulic classifiers, handling 368.274 tons of pulp per diem of 24 hr., receive as hydraulic water through the three classifying pockets 120 gal. per min. The discrimination of the classifier is well illustrated by the following comparison between the feed, first spigot, and first overflow:

Grade.	Tons Solid.	Gal. Water in 1 ton of feed.	Tons Copper.	Water Added
Classifier feed	368.274	1235	12.827	...
1st spigot.	120.425	284	5.183	70.2
2nd spigot.	32.963	110	1.689	36.0
3rd spigot.	23.873	95	0.823	13.8
Overflow.	191.013	746	5.032	...

The spigot products all go to fine jigs, and the overflow to 4-compartment spitzkasten. Four double 3-compartment fine jigs handle 177.261 tons per diem, from the classifier, the average copper content being 4.34%. The ratio of concentration is 1.91 into 1, and the extraction is 80.55%. The concentrate amounts to 92.806 tons, assaying 6.68% Cu, and the tailing is 84.455 tons, with a tenor of 1.77% Cu. The jigs have 23½ by 35½-in. screens, and the plungers are 21 by 35 in., making 200 strokes of $^9/_{16}$ in. per min. Each jig consumes 1 hp. The depth of bed is 4 in. The head-end screens are in one piece, 6 mesh, No. 16 wire, and the tail-end in two pieces, 8 mesh, No. 18 wire. The head-end screens last twenty days, and the tail-end fifteen.

The 4-compartment spitzkasten divides its 191.013 tons of feed into 24% spigot-discharge and 76% overflow. The work of the spitzkasten is seen in the table below:

	Weight Per cent.		Copper Per cent.	
	Spigot.	Overflow.	Spigot.	Overflow.
On 100-mesh	22.0	15.4	3.80	2.42
On 200-mesh	20.4	2.8	3.85	3.83
Through 200-mesh	12.6	21.0	4.63	4.66
Slime	45.0	60.8	1.82	1.85

The overflow is sent to two pulp-thickeners, 10 ft. diam. by 12 deep, classifying 145.170 tons of pulp into 21.5% spigot-product and 79.5 as overflow, the latter going to another spitzkasten system. The spitzkasten principle is not actually introduced here, the settling being accomplished by circulation of the pulp through 33 rectangular compartments, having a total capacity of 9900 cu. ft., and presenting a superficial area of 2170 sq. ft. These are handling 450 gal. of slime per minute.

As shown above, 325.028 tons of medium coarse jig-tailing, assaying 1.41% Cu, go to a shovel-wheel delivering its discharge to the Bryan mills. Of this, 18% is an overflow of slime and fine sand which is sent to the chip-catcher, and then to the spitzkasten; 82% only reaches the Bryan mills. There are four of these, 5 ft. diam. each, receiving 266.522 tons from the shovel-wheel, and 25 tons of middling from the Wilfley tables, making a total feed to each mill of 72.88 tons per 24 hr. This is crushed to pass a 1½-

Grade.	Weight, Per cent. Feed.	Spigot.	Overflow.	Tons, Solids. Feed.	Spigot.	Overflow.	Copper, Per cent. Feed.	Spigot.	Overflow.
On 20-mesh	8.0	24.0	0.5	29.462	28.902	1.239	3.86	2.98	1.80
On 60-mesh	26.0	51.0	13.5	95.751	61.416	83.459	5.03	5.13	2.58
On 100-mesh	10.0	8.0	11.0	36.827	9.634	27.263	4.30	5.88	3.46
On 200-mesh	8.0	2.0	9.0	29.462	2.408	22.306	4.50	5.58	6.18
Sand through 200-mesh	13.0	2.0	16.0	47.875	2.408	39.655	4.62	5.15	5.87
Slime through 200-mesh	35.0	13.0	50.0	128.897	15.657	123.927	1.70	2.22	1.70
Average	...	...	...	368.274	120.425	247.849	3.64	4.30	3.08

It is to be noted that the soluble copper in the feed constituted 0.14%, which of course does not appear in the subsequent products. The second and third spigot-products and the final overflow show equally good results. The following table briefly recapitulates the performance of the classifiers as regards extraction, the figures being reduced for convenience so as to show tons of copper at each stage,

mm. screen, delivering the product to de-watering boxes. The Bryan mills make 39 rev. per min., and require 18 hp. each. The die weighs 1661 lb., and lasts 120 days; the three tires weigh 3672 lb., and have a life of 240 days; and the five screens weigh 19 lb., and are worn out in four days. The following screen analysis represents an average of the crushed product from the Bryan mills:

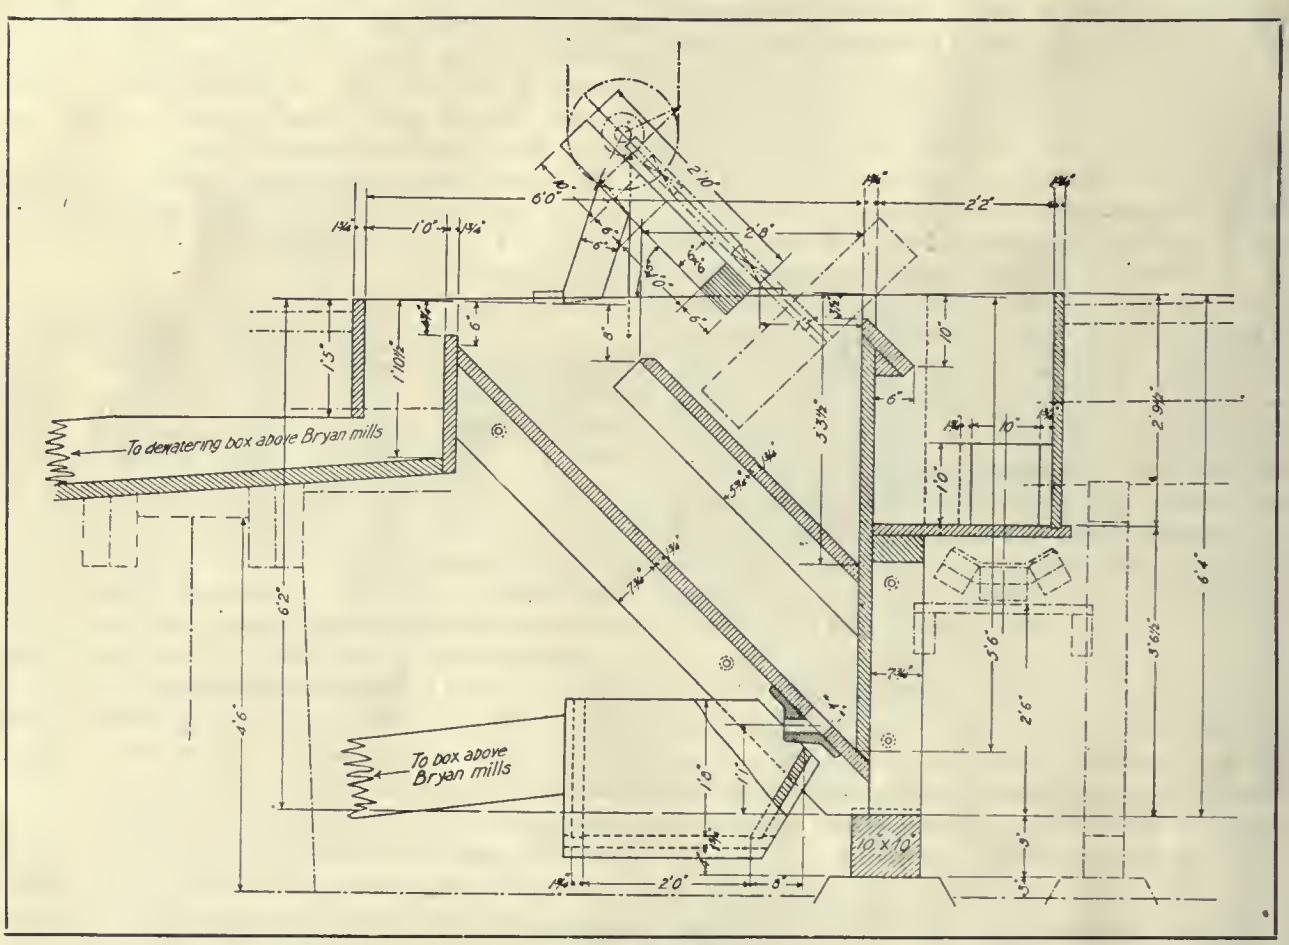
Grade.	Weight Per cent.	Pulp per day Tons.	Copper Per cent.	Copper per day Tons.
On 20-mesh	1.9	5.064	0.48	0.243
On 60-mesh	19.0	50.639	0.70	0.354
On 100-mesh	16.0	42.643	1.24	0.529
On 200-mesh	13.9	37.046	1.56	0.578
Through 200-mesh	8.2	21.855	2.15	0.471
Slime	41.0	109.275	1.28	1.399
Total	100.0	266.522	1.58	3.574

The de-watering boxes receive this product plus the spigot-discharge from the 4-compartment spitzkasten, making 312.365 tons in all, assaying 1.59% Cu, or 4.959 tons per diem. Of this total 92% is drawn off through a spigot and led to hydraulic classifiers for Wilfley table and fine-jig feed, while 8% overflows to round-tanks for the vanner-feed. The two classifiers, which are of the Richards goggin type, take 287.376 tons of pulp, assaying 1.56% Cu, and make four products, as follows: first spigot 60.50 tons, 1.8% Cu; second spigot, 36.20 tons, 2.18% Cu; third spigot, 20.54 tons, 1.89% Cu; overflow, 170.136 tons, 1.3% Cu. Hydraulic water at the rate of 150 gal. per min., is used, and the classification ratio is 2.26 into 1, making 117.24 tons of fine-jig and Wilfley-table feed, and discharging 170.136 tons to another spitzkasten, which treats this amount per day, making a fine-table feed of 50.42 tons, concentrated on six Wilfleys, and 119.716 tons of overflow which goes to a centrifugal pump delivering to the round-tanks.

The fine-jigs are two in number, of 3 compartments each, taking a total of 48.25 tons per diem, containing 1.8% Cu, and producing 9 tons of 5.9% concentrate, showing a concentration ratio of 5.36 into 1, and a 60.47% extraction. These jigs are fitted with screens 24 by 36 in., the head-screen being 6-mesh, and the tailing-screen 8. The bed is only 2½ in. deep, and the 21½ by 34½-in. plungers make 240 quarter-inch strokes per minute.

Nineteen Wilfley tables treat 109.41 tons of classifier and spitzkasten sand per day. The feed contains 1.84% Cu. The daily output of concentrate is 17 tons, with 7.6% Cu, the concentration ratio being 7.024 into 1, and the extraction 58.62%. The tailing amounts to 76.43 tons, with a copper tenor of 0.619% Cu. It is interesting to note that the headwater with the Wilfley-table feed contains 1.13% Cu. The 25 tons of middling are returned to the Bryan mills by an elevator 86 ft. long, made of 11-ply belting, with sixty 8 by 5-in. buckets. The elevator belt is driven from a head pulley 24 in. diam., and has a speed of 356 ft. per min. The buckets last five months.

A 6-in. centrifugal pump, working against a head of 25 ft., handles 119.716 tons of pulp and 25.98 tons of slime to three round-tanks, 10 by 18 ft. An 18-ft. elevator lifts the round-tank discharge to eighteen



Jig-Tailing Separator.

6-ft. vanners. These have smooth belts, 12 ft. long, driven 12 ft. in 2½ min., and set with an inclination of 7/16 in. per foot. The feed is composed of the following grades:

Grade.	Weight Per cent.	Solids Tons per day.	Copper Per cent.	Copper Tons per Day.
On 60-mesh	4.4	6.410	0.42	0.027
On 100-mesh	7.0	10.198	0.78	0.071
On 200-mesh	27.0	39.337	1.00	0.393
Through 200-mesh	12.0	17.483	2.19	0.283
Slime	49.6	72.268	1.19	0.859
Total	100.0	145.696	1.19	1.733

The extraction is 53.23% on a concentration ratio of 11.48 into 1, the total concentrate being 12.691 tons assaying 7.26% Cu. The 133.005 tons of tailing carry only 0.6% Cu. These go to the tailing launder, and are sampled on the way to the dump by an improved Scobey sampler, belted to the vanner drive-shaft, and cutting the whole stream once every seven minutes.

Another spitzkasten takes 58.505 tons of slime overflow from the Bryan-mill shovel-wheel tank, making 50 tons of pulp for the Wilfleys, and 8.505 tons of slime which goes to an Aldrich pump. There is also a 4-pocket classifier handling 31.211 tons of spigot-discharge from the pulp-thickeners, and 50 tons from the previously mentioned spitzkasten. This makes a roughly classified feed of 81.211 tons to eight Wilfley tables. The Aldrich pump is of the triplex plunger type, 13 in. diam., 10 in. stroke, making 32 strokes per minute. Its capacity is 800 gal. per min. It handles 400 gal. per min., plus 8.505 tons of slime, delivering its load to the feed-water box at the head of the mill.

The eight Wilfley tables treat 81.211 tons of pulp and 5.24 tons of the middling made. The feed contains 2.03% Cu; the concentrate amounts to 8.517 tons with 9.2% Cu, being a concentration of 9.64 into 1, and an extraction of 48.03. The 72.694 tons of tailing, assaying 1.2% Cu, is discharged into the tailing-launder.

From the large spitzkasten 113.959 tons of slime are sent to eighteen 6-ft. vanners, making 10.2 tons of concentrate, raised from 2.38% Cu in the feed to 10.52 in the finished product. The ratio of concentration is 8.14 into 1, and the saving is 38.68%. The tailing, 103.759 tons, with 1.63% Cu, is delivered to the tailing-launder.

The succeeding table illustrates the extraction of one section of the mill up to this point the distribution of the extraction being shown in percentages of the whole sand in the last column:

Machine.	Concentrate Tons.	Copper Per cent.	Copper Tons.	Sand Per cent.
Jig No. 9	33.704	5.32	1.793	11.27
Jig No. 14	15.275	5.82	0.890	5.59
Jig No. 19	20.077	5.72	1.148	7.22
Jig No. 22	22.097	5.74	1.268	7.97
Jig No. 24	92.806	6.68	6.199	39.00
Jig No. 34	9.000	5.90	0.531	3.34
Wilfleys No. 35	17.000	7.60	1.292	8.12
Vanners No. 40	12.691	7.26	0.921	5.79
Wilfleys No. 45	8.517	9.20	0.783	4.92
Vanners No. 47	10.200	10.52	1.073	6.72
Totals	241.357	7.00	15.898	100.00

The tailing discharge to tailing-launder is shown below:

Machine.	Tailing Tons.	Copper Per cent.	Copper Tons.
Jig No. 34	39.250	0.86	0.337
Wilfleys No. 35	76.430	0.81	0.619
Vanners No. 40	133.005	0.60	0.812
Wilfleys No. 45	71.694	1.20	0.847
Vanners No. 47	103.759	1.63	1.701
Overflow No. 38	34.504	1.20	0.414
Totals	458.643	1.03	4.730

The ratio of concentration is 2.9 into 1, and the total extraction of copper up to this stage of the process is 77.07%. The tailing from both sections of the mill, 905.287 tons in all, is received in a coarse-sand tank, which is an inverted pyramid, 12 by 12 by 12 ft., having a capacity of 612 cu. ft. Through a ⅞-in. spigot 292.672 tons are discharged, assaying 0.65% Cu, leaving 612.609 tons of overflow containing 1.21% Cu. The spigot-product is sent to the tailing-pond, and the overflow to the fine-sand tank, 24 by 12 by 9 ft., with a wedge-shaped bottom, having a capacity of 1380 cu. ft. The four compartments discharge through eight ¼-in. spigots, combining their product with the fine sand from the mill, which all goes to the fine-sand plant where it is concentrated on 10 Card tables and 40 Frue vanners. The Card tables receive 53 tons assaying 0.98% Cu, yielding 2.258 tons of concentrate with 5.7% Cu. The concentration ratio is 23.47 into 1 and the extraction 24.74%. The 50.742 tons of tailing go to a settling tank, the clear water from which is sent to the precipitating plant. The 40 Frue vanners treat 215 tons assaying 1.12% Cu, and yield 7.945 tons of concentrate assaying 9.2% Cu. The tailing amounts to 208.055 tons, with a copper tenor of 0.81%. The concentration ratio is 27.06 into 1, and the recovery 30.35%. The same disposal is made of the tailing as in the case of the Card-table tailing. The total feed is classified, the spigot going to the Card concentrators and the overflow to the vanners. The concentrate is elevated to the railroad bins, and the tailing is discharged at intervals from the settling-tank to the tailing-pond. At this point a recovery of 250 gal. of clear water per minute is effected.

The overflow from the above fine-sand tanks and fine-sand tailing tanks, is treated in four sections of V-bottom tanks with 77 compartments, 5 by 32 ft. each, and 8 ft. deep, making a superficial water-area of 12.320 sq. ft. The pulp carries only 4.05% solid matter, but the total solids amounts to 1300 tons daily, with a copper-tenor of 1.2%. The spigot-product consists of 325 tons of fine sand assaying 1.42% Cu, and 975 tons of what is called in this mill 'absolute slime,' containing 1.04% Cu, or 10.14 tons of copper, while at the same time 1500 gal. of clear water per minute is recovered.

The slime-plant treating this material consists of fifty 6-ft. corrugated-belt Frue vanners, with a belt-travel of 12 ft. in 2½ min., the inclination being ½ in. per foot. The total daily feed is 460 tons, of which 96% will pass a 200-mesh screen. The copper content of the feed is 1.16% Cu. The concentrate produced is 13.403 tons, assaying 7.53% Cu.

leaving 446.597 tons of tailing carrying 0.97% Cu. The concentration ratio is 34.32 into 1, and the extraction 18.9%. The second recovery made on the tailing discharged past the Scobey samplers is as follows:

Machine.	Concentrate Tons.	Copper Per cent.	Copper Tons.
Card tables	0.537	5.70	0.031
Sand Vanners	1.891	9.20	0.174
Slime Vanners	3.350	7.53	0.254
Totals	5.778	7.94	0.459

This amounts to a further saving of 10% of the copper discharged from the upper mill. It should be stated that this subsequent concentration plant represent an annex to the old mill.

The total water recovered from the settling system, including tailing-tanks, is 3000 gal. per min., to which the overflow from the concentrate bins adds 900 gal. This quantity is raised 150 ft. by two, Aldrich, triplex, vertical, belt-driven, plunger pumps 18 by 18 in., requiring 40 rev. per min. The pump-column is 16 in. diam., and the indicated horse-power is 225. The water is received by two round tanks at the head of the mill, each having a storage capacity of 100,000 gallons.

The Scobey tailing-sample is at intervals carefully screened wet, then dried, and each size weighed and assayed. The residues are panned, using a pan for the coarser products, and a plaque for the finer. The results of such a test are shown in the following table, on the basis of one ton:

Grades.	Weight Per cent.	Weight Pounds.	Copper Per cent.	Copper Pounds.	Pan concentration, Ratio.
On 20-mesh	2.5	50.00	0.82	0.21	217.39
Pan concentrate	...	0.23	0.42	0.01	into
Pan tailing	..	49.77	2.60	0.20	1
On 100-mesh	27.0	540.00	0.41	2.48	99.0
Pan concentrate	...	5.45	0.46	0.18	into
Pan tailing	...	534.55	3.40	2.30	1
On 200-mesh	11.5	230.00	0.43	1.15	30.99
Pan concentrate	...	7.47	0.53	0.46	into
Pan tailing	...	222.53	6.16	0.69	1
Through 200-mesh	10.8	216.00	0.31	3.89	5.53
Pan concentrate	...	39.05	1.80	3.37	into
Pan tailing	...	176.95	8.64	0.52	1
Slime	48.2	964.00	0.29	12.27	
General tailing	100.0	2000.00	1.27	20.00	38.31
Pan concentrate	...	52.20	1.00	4.02	into
Pan tailing	...	1947.80	7.70	15.98	1

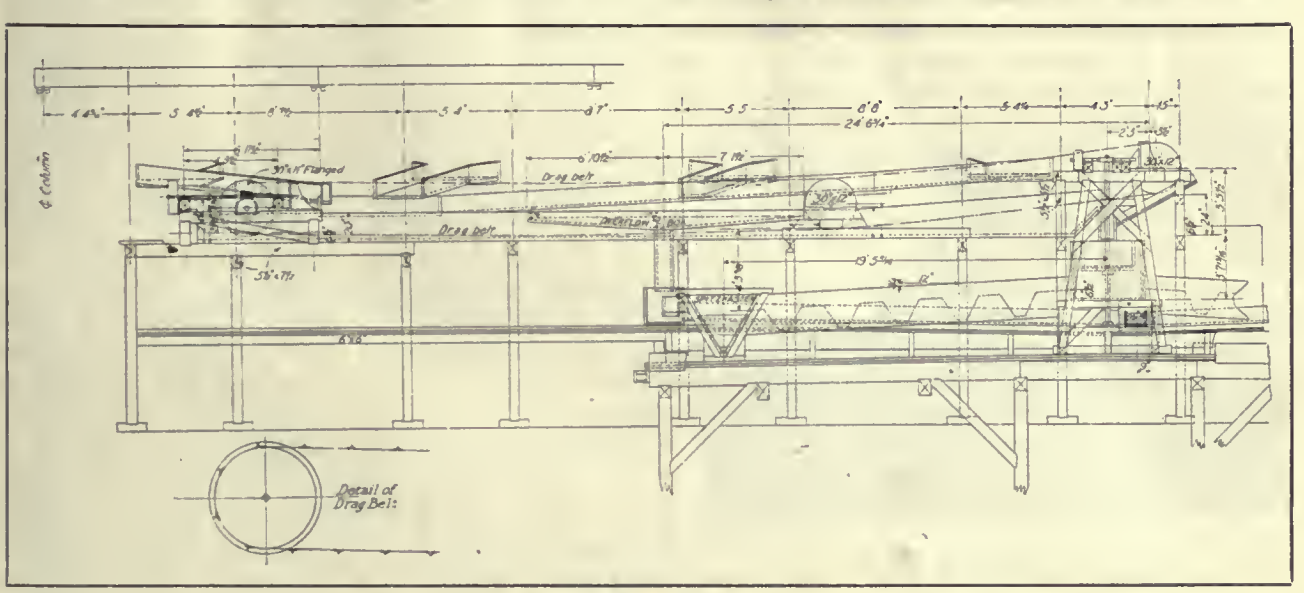
The pan and plaque concentration thus represents a possible saving of 20.1% against an actual recovery by Card tables and vanners of 10%. The general sample of the tailing finally discharged to the tailing pond carries 0.84% Cu, while the pan-tailing shows a possible minimum of 0.82. L. D. Ricketts, general manager for the Cananea Consolidated Copper Co., acting under the conviction that, as the waste of past generations of miners is ore to the present metallurgists, so the depleted tailing, carrying only 0.82% copper, may be valuable in the days to come. Hence it is carefully imponnded. The tailing-launder is provided with a series of pockets, 12 ft. centre to centre, which discharge across the width of a deep gulch, and, flowing toward the up-canyon side of the tailing-wall thus produced, it builds a sloping dam that has proved safe against the pressure of the impounded water as well as against the wash of floods in the rainy season, the latter being further cared for by a spill-way. The catchment-area tributary to the canyon above the dam is relatively small. A floating barge is placed at the head of the pond, carrying a centrifugal pump, electric-motor driven, which pumps 1100 gal. per min. of the greenish coppery water through wooden pipes to the precipitating tanks. The tailing-dam now stands 90 ft. high, with a slope from crest to toe having a mean of about 40°. The sand in this tailing-dam has a maximum diameter of 1.5 millimetre.

The elaborate investigation of every detail of the milling process here is conducted under the direct guidance of David Cole, the assistant general manager for the company. Mr. Cole is the designer of the exceedingly simple and efficient de-watering shovel-wheel previously mentioned and illustrated. He has also designed a simple and clever separator for dividing sand from slime, which is now being used to prepare sand and slime for different concentrators in the plant. This so-called 'drag-belt separator' consists of a long shallow trough, with a slack belt traveling in it and held down by an idler so that scrapers on the outer side of the belt just escape the bottom at mid-length. The pulp enters at one end, the settling sand as it accumulates is dragged forward and over the farther end of the trough at a speed of 50 ft. per min., while the slime overflows by a weir-notch along one side, extending one-third the length of the trough. The following screen-analysis demonstrates the efficiency of the apparatus:

Grades.	Feed Weight Per cent.	Slime Weight Per cent.	Sand Weight Per cent.
On 20-mesh	1.1	...	10.2
On 40-mesh	5.1	...	21.8
On 60-mesh	9.1	...	22.9
On 80-mesh	3.8	...	8.8
On 100-mesh	6.4	5.6	10.5
On 150-mesh	11.1	10.9	10.7
On 200-mesh	4.7	5.4	2.5
Through 200-mesh	8.1	11.7	5.1
Slime	44.0	64.0	4.1

As the ore to mill varies, the extraction also fluctuates within normal operating limits. The saving during the month of April, to which the foregoing

outline applies, was 78.81%, and the total daily recovery of concentrate ready to go to the reverberatory smelter averaged the equivalent of 494.27 tons of metallic copper. The labor required for this plant, treating 1400 tons per diem, is as follows: one mill foreman, $175 per month; one head foreman, $5 per 10-hr. shift; one jig-man, $3.50 per each 8-hr. shift; one vanner-man, $3.50 per 8-hr. shift; one engineer, $4 per 8-hr. shift; three machinists at $4.25 per each 10-hr. shift. These constitute all the Americans employed. The Mexican labor consists of two jig-men, two millmen, two stable-men, and to vanner-men each at ₱3.50 per each 8-hr. shift; four helpers at ₱2.50 per each 8-hr. shift. There is also a repair gang of four Mexicans receiving ₱4 each, and six feedermen at ₱3. For loading concentrate there are six Mexicans paid ₱3.50 per day each, and one American foreman receiving $4. The sampling is under the direction of an American receiving a salary of $125 per month, under whom are four helpers who are paid ₱3.50 each for an 8-hr. shift. Common labor is employed in many situations, bringing up the total number of men engaged in and around the mills, to 304.



Cole Drag Belt Scraper.

Honduran mining laws are based on the famous 'Ordenanzas de Mineria' of Spain, and give the alien the same rights as the native. Under this law anyone can denounce up to 1000 hectares (about 2400 acres) for mining purposes and pay a yearly tax of 50c. silver (20c. gold) per hectare. Some 700 mines in all have been denounced. While the country is undoubtedly richest in silver, denouncements have also been made of gold, lead, copper, kaolin, crystal, iron, opal, marble, saltpetre, aluminum, chalk, coal, antimony, zinc, nickel, and asphalt. Petroleum is also found, and an exclusive privilege to extract and export it has been granted. The iron found is said to be highly magnetic and rich copper-silver ore is found in the mines of Guanacostre, in the department of Olancho. A recent discovery of copper in the department of Yoro has been reported, in which the veins are said to run as much as 10, 12, and 14 ft. in width. At the present time only two or three companies are in successful operation in Honduras. The New York and Honduras Rosario Co., operating in San Juancinto, in the department of Tegucigalpa, is the only one doing work upon an extensive scale. It employs about 1800 men, of whom 30 to 40 are foreigners, mostly Americans. During 1908 it mined and milled 29,516 tons of ore which yielded 976,450 oz. silver and 16,664 oz. gold.

Coal mine accidents in the United States in 1909 are reported in a bulletin of the Geological Survey. The total number of persons killed in the year is given as 2412; injured 7979. The disaster in the mine of the St. Paul Coal Co., at Cherry, Ill., is not included because the report of the Illinois State mine inspectors was made for the fiscal year ended June 30, while the Cherry fire occurred in November. The number killed in the Cherry accident, has been reported as 393. The number of non-fatal accidents, 7979, is unprecedentedly high, exceeding the figure for 1908 by more than 1200. The number of fatal accidents, 2412, is smaller by 38 than that for the preceding year. Comparisons are not quite fair, however, because the reports for 1909 were more complete than those for any preceding year. As usual, the greatest number of fatal accidents was due to falls of roof and coal, which were responsible for over 49% of the total number of fatalities. Explosions of gas and dust caused less than 14.5% of the total number of deaths.

In copper mines where the water is strongly acidulated and carries an appreciable amount of copper in solution, the destructive effect of the acid water on the ropes, pump-column, pumps, skips, or cages, and any other iron or steel objects with which it comes in contact, either in the mine or on the surface, may in some measure be abated if the precipitation of the copper on old iron scraps (a common practice at the surface) be done underground before the water is pumped or hoisted to the surface. The reaction of the acid water on the old iron not only precipitates the copper, but removes considerable acid from the water as well.

Deep Mining in Transvaal

By Roland Gascoyne

The question as to the ultimate depth at which it will be possible to successfully mine on the Rand has been attracting the attention for some time, but as the mines increase in depth the limit to deep mining appears to be further removed. Granted that in depth the banket reefs maintain their present average, there is every indication that successful mining operations will be continued on the Rand to a far greater depth than seems possible in any other mining field. Generally speaking the principal anticipated bugbears to the success of deep mining have been two only, increased temperature with depth, and increased pressure of the superincumbent strata. The third, that of deep winding, seems to be losing most of its force as it becomes necessary to wind from such depths as prevail on the Rand today. It does not appear necessary to go into that matter as it is clear that winding in one clear lift from the depth of 5000 ft. presents no unsurmountable difficulty. The question then resolves itself into considering the difficulties attending deep mining on the score of temperature and pressure.

The question of temperature received attention some sixteen years ago when Hamilton Smith wrote a letter on the subject to the *Times*. At that time actual mining on the Rand had only reached about as many hundred as it has thousands of feet in depth today, and the main observations were confined to the Rand Victoria bore-hole. At a depth of 200 ft. the temperature was 67.2°F. and it was recorded that the temperature gradually increased to 95.3°F. at a depth of 2494 ft., which was taken to indicate that at a depth of 3000 ft. the temperature would be 100°F. These observations seemed to show that the temperature increased one degree for every 82 ft. in depth, but for some reason this rapid increase of temperature is not borne out by later observations in other parts of the Rand. In fact, Mr. Smith at the time seemed to doubt the accuracy of the observations.

A year later Andrew J. Crosse made an important series of observations at the Ferreira and Crown Deep mines, at the former obtaining a temperature of 69.1°F. at a depth of 808 ft., and at the latter a temperature of 70.7°F. at a depth of 1030 ft. These observations seemed to show roughly an increase of one degree Fahrenheit for every additional hundred feet in depth: an increase likewise not confirmed by subsequent observations. Four years ago Hugh F. Marriott read a paper before the Institution of Mining and Metallurgy, on 'Earth Temperatures on the Witwatersrand Gold Fields,' in which he gave results of observations made in shafts and bore-holes varying in depth from 500 to 3916 ft. from the surface, no less than seventeen observations being taken at different mines and varying depths. In the Jupiter mine at a depth of 3916 ft. the rock temperature was 83.25°F. From these observations the following results were tabulated, showing an increase to 102.35°F. at 8000 ft. of depth.

Depth feet.	Deg. F.	Depth feet.	Deg. F.
1000	68.75	5000	87.95
2000	73.53	6000	92.75
3000	78.35	7000	97.55
4000	83.15	8000	102.35

The observations show that the results vary somewhat, but the average increase over the whole list of mines where observations were made, showed an increase of underground temperature of 1°F. for every 208 ft. in depth. Since the above observations were made, another 500 ft. has been added to the depth of the deepest mines, and the latest investigations show an increase of 1°F. for every 255 ft. in depth, which, if correct, would seem to indicate that the temperature gradient on the Rand is the lowest in any mining field in the world, not excepting that even at the Calumet & Hecla mines in North America.

It will be seen, therefore, that the deep mines on the Rand will have little to fear from the increase of temperature due to the depth, and that the existing deep mines can double their present depth before experiencing any difficulty or trouble owing to the growing temperature. That this is so is proved by the fact that at the Jupiter mine, well over 4000 ft. deep from the surface, mining operations today are being carried on without any resort to fan ventilation; a condition of affairs which speaks volumes for the ease with which deep mining is destined to be carried on at the Rand. If, in the absence of any artificial ventilation, mining operations on the Rand can be carried on to a depth exceeding 4000 ft., it is evident that with ventilation receiving adequate attention it will be easily possible to carry on work to at least double the present depth. Should the temperature gradient continue to decrease as greater depths are reached, it does not seem unduly optimistic to predict that mining operations may perhaps be carried on to a depth of 15,000 ft. without any serious inconvenience being suffered through the increased temperature due to depth. In making this calculation, it must not be overlooked that the Rand is blessed with a fairly abundant supply of colored native labor, capable of doing manual work at a much higher temperature than white labor, and as the latter can work in the Rand underground atmosphere up to a temperature of 90°F. without feeling any serious inconvenience, and that in a comparatively unventilated mine, it is evident that native colored labor in a properly ventilated mine will be able to give much better results at a considerably higher temperature, and on that account it would probably appear that as regards temperature, deep mining on the Rand has but little to fear.

The difficulty with regard to the growing pressure of the superincumbent strata as the depth increases is one that has not yet been fully realized on the Rand, and it is only during the last few months that the trouble has shown itself in a serious aspect. There have been several instances where damage has been done to the shafts by the subsidence of the strata, especially where pillars left in support of the shaft have been too small or were left strictly in accordance with the local Mine Regulations. These if carried out in mines with a steep inclination, will

cause the pillar to be left not altogether in the best position; that is, unless the pillars are left much larger than actually required.

There seems to be an impression on the Rand that the quartzite hanging and foot-walls are so cohesive that even when the whole of the reef is extracted at considerable depths there will be no movement whatever of the hanging wall. As a matter of fact the quartzite will move more rapidly than shale or slate, and when it moves it is liable to move freely. This is easily discerned where mining on the long-wall system is followed, for when the hanging wall or roof contains a fair proportion of shale, it shows a steady bending movement, but if it be altogether composed of sandstone, the hanging wall, once it commences to subside, sinks rapidly, and frequently in such masses as to completely close the working levels of the mine. That the weight of the superincumbent strata is a factor to be reckoned with is shown by the recent accident at the Cinderella Deep mine, where sixteen natives lost their lives through a pillar collapsing at a depth of 4000 ft. from the surface. During June and July several similar but smaller accidents have occurred on the Rand, thus showing that mining operations are reaching such a depth as to require full recognition of the fact that the hanging wall, once it begins to move at such depths as 4000 ft. and over, will be difficult to control by the old method of leaving pillars.

There are also many engineers and mine managers who believe that beyond a certain depth the strength and cohesive nature of the hanging wall will prevent any movement or subsidence. This view may have been adopted owing to hanging walls over 1000 ft. thick rarely collapsing all the way to the surface and giving such pronounced indications as the presence of surface cracks and fractures. A little observation, however, will show that even where mining operations are carried on over 1000 ft. deep, there is a subsidence of the surface, but before the movement takes place a sufficiently large area has to be excavated underground to admit of the hanging wall moving as a body and before a fracture can be formed at the surface the hanging wall and foot-wall meet and prevent further subsidence. In other ways it is clear that actual subsidence will take place, not only when the whole reef has been worked, but recent indications would seem to show that at the depth some of the mines are now working on the Rand, the hanging wall will collapse in time, notwithstanding the fact that nearly one-half of the reef has been left standing behind in the shape of pillars. The actual time that will elapse before the hanging wall begins to move will naturally depend upon circumstances, but it is clear that the ultimate maximum pressure exerted on any pillars or other supports left must be the actual weight of the superincumbent strata. The Rand quartzites may be taken to weigh 1.222 lb. for each square inch of area one foot in depth, so that for each thousand feet in depth the weight will be 1222 lb. per square inch, and at 5000 ft. deep the ultimate pressure per square inch will be 6110 lb. It follows that at 10,000 ft. the pressure will be 12,220 lb. Experiment has shown that the quartzite hanging wall of the Robinson mine will crush at a pressure of 8170 lb. and will fracture with a pressure of 6489 lb. to the square inch, so that the real difficulties of deep mining will begin as regards superincumbent pressure, when a depth of 7000 ft. is attained. It is difficult to draw a hard and fast line as to where the preliminary difficulties will begin, but seeing that as soon as a pillar begins to fracture and fly, accidents are likely to occur, and as this will commence long before crushing strength of the quartzite is reached, the risk of pillars being crushed would seem to commence at a depth of 3000 ft. and continue to increase in intensity with the growing depth. At the Cinderella Deep the accident occurred at a depth of 4000 ft., but there are so many different conditions to consider, such as the presence of dikes, lines of weakness, and proportion of reef left standing in

Ferreira Deep Shaft.

the shape of pillars, that it becomes difficult to establish a rule and only a rough and ready calculation can be made, even if all the circumstances are known. The best method of procedure would undoubtedly be to take the maximum possible pressure as the guide under all circumstances and never allow any condition to prevail underground likely to come into conflict with the necessary rule to be observed against this possible maximum pressure. It is clear that between the depths of 3000 and 7000 ft. the leaving of pillars must be attended with some degree of risk, and if mining operations are to be carried on with the maximum degree of safety, a method of mining will have to be adopted whereby the pillars will be worked out in a minimum time so that as the depth beyond 4000 ft. increases the sooner the pillars will have to be worked. At a depth of 7000 ft. there will be considerable risk in leaving any pillars at all, and then a system of working allied to long-wall methods may perforce have to be employed.

While it is clear that in a good many instances the real dangers due to the pressure ultimately to be reached, do not appear to be recognized, it is satisfactory to notice that steps are being taken to avert the danger. Prominent among them is the adoption of the sand-filling process, whereby all the exhausted areas of the mine are filled solid by water-borne tailing. It may be pointed out that there is also a ten-

dency to modify the present system of working so as to better suit the sand-filling process and the most suitable modification seems to be that of leaving much larger pillars so as to permit of secondary working and the working of bigger stopes to be completely sand-filled before the pillars are touched, so that gradually and perhaps unconsciously a method of working is likely to be evolved similar in many respects to the stope and pillar system of working as practised in coal when a moderate depth is attained. As the mines increase in depth even this system of working will become obsolete until at a depth of 7000 or 8000 ft. it seems probable that the long-wall method, coupled with sand-filling, will be adopted. When such a depth as 7000 ft. is reached, the underground conditions, more particularly as regards the inclination of the reef, will be more suited to the adoption of the long-wall method of working than the conditions at the existing depths, and it may be urged that on that account principally, the long-wall system or some modification of it will be adopted, but at all events it seems clear that when such depths are reached the adoption of such a system of working may become general.

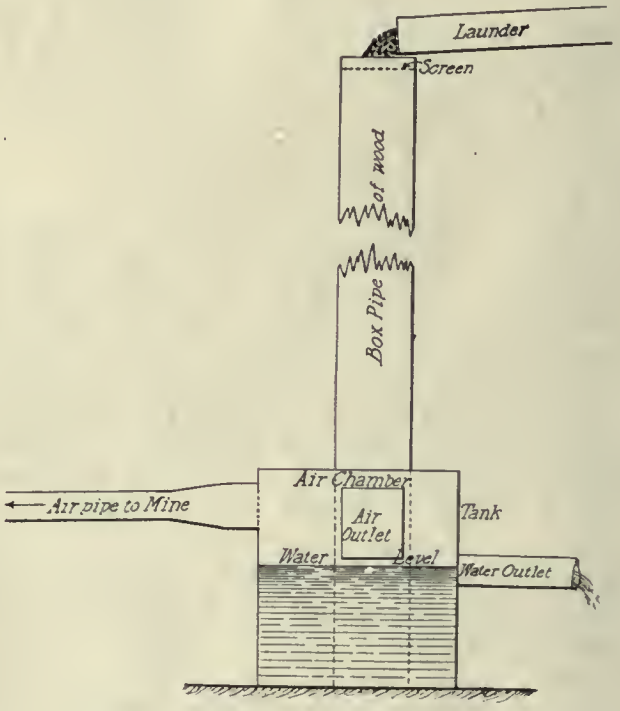
As greater depths are being actually attained on the Rand, the depth limit to deep mining seems to recede until it is wellnigh impossible to fix on a limit. Even the temperature gradient flattens with the increasing depths, and if the temperature at 120°F. be taken as the limit to economical working, the latest observations indicate that this will only be reached in 15,000 ft. from the surface. If, on the other hand, the estimate be based on difficulty caused by the weight of superincumbent strata and compared with the ultimate crushing strength of the Rand quartzites, using the same method of calculation as the last Royal Commission on deep mining in England adopted, a depth of 15,000 ft. as the probable limit to deep mining on the Rand is also reached. Providing mechanical engineers can devise a successful method of winding from such a depth, there seems no reason why the ultimate limit to deep mining on the Rand should not be extended to a depth of 15,000 ft. from the surface.

Crude petroleum often contains water, fine sediment, and sand. If the presence of any, or all, of these in the oil is suspected, they may be detected by pouring a quantity of oil on a clean plate of glass and allowing it to spread over it in a thin even sheet. If water be present it will appear, if held up to the light, as small, bright, light-colored spots on the glass. These may be distinguished from air bubbles by pricking them with the point of a pin. If sand be present in the oil the grains will show as small blisters on the otherwise smooth surface of the oil.

Where there is a scarcity of water for milling purposes, water from the mine is sometimes used, but when this seems necessary where plates are used, it should first be ascertained that the mine-water contains no mineral in solution that is detrimental to successful amalgamation. Some minerals cause discoloration of the plates, and sometimes altogether prevent amalgamation. Arsenic is one of the substances which act in this manner. If the water is to be used in concentration only, the presence of the minerals in solution will make no difference. Salt water is not detrimental to amalgamation.

WATER BLAST FOR VENTILATION

A simple, cheap, and effective means of ventilating mine tunnels, shafts, and other workings, may be applied at any place where a stream of water, having a head of 30 ft. or more, is available. The entire apparatus consists of a wooden box, or pipe, 30 ft. or more in length and 12 inches in diameter, set vertically, and provided with a coarse screen of wire or perforated metal near the top, though this screen is not absolutely necessary, as its chief function is to break up the stream of water into drops. This box must be secured at the top to keep it from falling. This may be easily done by either braces or by building a light trestle out to it from the hillside. The water is brought to the top of the box in a small flume or launder, which discharges into the upper



end of the upright box. The falling drops imprison a large amount of air as they fall, and this air, being unable to escape upward through the falling stream, is carried to the bottom of the pipe, where it escapes through openings in the side of the vertical pipe, and accumulates in an air chamber, from which it passes out through a pipe-line to the working face, or wherever desired in the mine. The force of the current of air depends, to a great extent, on the height of the falling column of water—the higher the water column the greater the force of the air-blast. A 30-ft. fall has been known to drive an abundant supply of air to the face of a drift at a distance of 600 ft. from the ventilating plant. It will be observed that a liberal-sized air-chamber is provided in the tank above the surface of the water, in which the air accumulates. The water-level and outlet in the tank should be several inches below the level of the air outlet to the mine.

Geology of Hostotipaquillo Ore Deposits

By S. J. Lewis

A complete description of the Hostotipaquillo field, in the State of Jalisco, Mexico, even in the narrow limits indicated by the map (Fig. 1) is not now possible, but the following notes at least constitute material toward such a study. They are the result partly of geologic studies made by the writer for Cinco Minas and of the development work incident thereto in working out the position of the orebodies, and partly of later similar work in connection with other properties in the vicinity. The district is now so well known that all reference to any but the geological features may be omitted. The geology is so closely related to the ore deposits as to merit close study. The district in general, though it has produced millions of pesos worth of high-grade ore, will probably be best known in the future for its remarkable extensive deposits of low-grade, silver-gold, milling ores.

Fig. 1. Geology of Hostotipaquillo District.

Whether its copper production will ever become noteworthy is a question for the remote future. The type ore of the district is quartz, cementing a breccia of the country rock, impregnated with sulphides of silver associated with gold; and in some parts of the district with sulphides of the base metals.

The Santiago river seems to be the physiographic axis of the district: on the west side are both early and late flows; on the east side only the early lavas. On the west side occur all the important ore deposits of the area described, with the exception of the San Pedro Analco mines. The ore deposits on the east side are usually in cooling-cracks in the andesite sheet, and are quartz veins impregnated with base sulphides. Galena carrying little or no silver is usually present, generally accompanied by zinc. None of these deposits are of economic importance, save the San Pedro Analco mines already mentioned. The ore deposits are associated in a general way with warm springs, similar to those at Tequisquiapan, in Querétaro, near the Ajuchitlán mines. The principal springs near Tequila are in the Tecomil barranca, and flow altogether about 60 cu. ft. per second, at a temperature of about 70°F. They are scattered from near the top of the mesa down along the barranca for a distance of two miles, nearly to the Santiago river, and gush out of broken, much-brecciated andesite. Similar springs exist near the Espada and San José mines, near the river, closely associated with the mineral veins.

The district was formerly one of intense volcanic activity. The country rocks are principally andesite and basalt, with flows of rhyolites. The lavas have in later times been intruded by stocks of dacite. The oldest of the flows is the andesite, part of the eruptive sheet that covered so much of the Plateau region in Cretaceous times. The basement rock is exposed in but one place, a deep arroyo tributary to the Santiago river, leading down eastward from the Cerro de Cinco Minas. It is a fine-grained, dark-green, diabasic rock, showing much hornblende, very heavy, hard, and tough. In the river bed itself it is observable at this point only as loose blocks mingled with other débris. It is in place in the arroyo. A few miles to the north of this point, near the San Pedro Analco ferry, the basement rock emerges as an important uplift of trachyte-syenite, through which the river has cut its way down for over 3000 ft. It appears to have been a peak of the Cretaceous topography, antedating the andesite flows. It is of importance as determining the character of the mineral veins in its vicinity. The andesite sheet barely covered it at the high point, growing thicker as one goes north toward the San Pedro Analco mines. Fissures in the thin portion of the andesite are lean and carry base sulphides; the same fissures further away become strong quartz veins carrying silver, and at some points these become workable deposits.

The andesite shows great variation in color and texture in different parts of the district. At Cinco Minas it is grayish white, fine grained, and shows very few porphyritic crystals; from this it varies through many shades of blue to the dark purple characteristic of the San José region near the river. This phase frequently shows large phenocrysts of feldspar. In the Tequila area the andesite is buried under successive flows of basalt which poured out of the Tequila volcano in Tertiary times, forming the present rim-rock of the river canyon-walls. Here the present thickness of the basalt flows is some 2000 ft. It is well shown in the lower end of the Cinco Minas canyon, near the Balbaneda. As one gets farther away from the volcano the basalt thins, finding its northwesterly limit near the Tepic boundary. The Tequila volcano is a conspicuous landmark, being typically conical in form, the top truncated and cup-shaped, with a volcanic plug rising from the centre. Its surface is covered with flow rhyolites, which followed old lines of weakness in making their way to the surface; and with fragments of black obsidian of every size from the smallest to masses of as much as a cubic yard.

The quiet flows of basalt were succeeded by a period of subsidence, during which much of the topography was submerged; explosive eruptions took place from the Tequila centre, obsidian fragments from which are numerous in the conglomerate beds exposed by railway and arroyo cuttings. The

particles forming these beds were evidently sorted under water, and include pebbles of andesite, basalt, and other flows, and in the Balbaneda canyon near Cinco Minas, in conglomerate beds overlying the great rhyolite flow, pebbles of quartz have been observed. The elevation to form the present topography is geologically quite recent.

At no point has the basalt been observed occurring as a dike. The remarkable cooling-prisms shown in the photograph (Fig. 2) were exposed by a cut on the new road built at Cinco Minas. They are nearly horizontal, about 12 ft. long and 3 ft. diam. The horizontal position is due to their having been thrust over from the vertical during the period of vein-formation in the Cinco Minas area. They overlie andesite, which in turn overlies a great stock of dacite, which coming up from the west, as do most of the intrusive masses observed here, carried before it a portion of the andesite sheet, displaced the basalt flows immediately above, and came to rest near the top of Cinco Minas peak. The dacite is found only on the west side of the mountain, never on the river side. From the horizontal blocks shown, the basalt can be traced westward without interruption into

Fig. 2. Displaced Basalt Flow, Cinco Minas.

the normal vertical position, the public road running over the tops of the prisms for half a kilometre. The cooling was evidently slow, the prisms sub-dividing longitudinally into thin layers parallel to the faces, so that the exposed upturned ends are literally a mosaic of concentric figures. This basaltic rock differs in this respect from the true basalt found in the Balbaneda canyon, which is in small simple five-sided prisms without tendency toward splitting. Intermittently with the basalt flows occurred numerous flows of rhyolite and stocks of dacite, the latter of which seem to have been of prime importance in determining loci of ore deposition. Every ore deposit of economic importance which the writer has examined in the region is closely associated with such an intrusion. The genesis of the Cinco Minas ore deposits is particularly interesting. The dacite stock above referred to, forms the foot-wall of the deposit proper, the hanging wall being the andesite sheet pushed up by the intrusion. The andesite is thus presented on the surface as a narrow strip, about 500 metres wide, highly decomposed, associated on its western edge with mica-like particles with a coppery lustre. Similar rock occurs on the western edge of the Santo Domingo deposits farther north. In horizontal section, the dacite stock is about 200 metres across from southeast to northwest. The chemical affinity of the highly silicious dacite with the more alkaline andesite has been favorable to ore deposition. The resulting vein consists partly of mineralized brecciated particles of country rock surrounded by the precipitated quartz, and partly of altered hanging wall rock. The rock has been mineralized from the foot-wall outward, ending in a thick soft gouge. This seems to be typical of the veins in the district. The vein is in places over 90 ft. in thickness. At both ends of this deposit, the fracture continues in the andesite, and has been subject to the same vein-forming processes, though to less degree. Both north and south then of the original Cinco Minas ore-shoot, important deposits have been formed; both foot and hanging being andesite, generally speaking, though dacite has been observed in the hanging wall at the north end. A succession of local enrichment faults approximately at right angles to the strike has given the orebodies to the south great economic importance. In this area belongs the bonanza body taken out by former owners, as well as the continuation downward of the same, found in June of the current year. As permission to go into details has been withheld by the management, only the general features of these interesting structures can be touched upon here. In general, the evidence is strong that persistent bodies of primary ore of commercial grade were formed in the vicinity of the dacite intrusion as a result of favoring precipitation conditions; that where the fractures are wholly in the andesite, the ore, though still of commercial grade, contains a slight admixture of base sulphides; and that when so formed, local faults have in many cases given opportunity for secondary enrichment that has resulted in the formation of bonanza orebodies. That the original deposit is of primary origin seems certain. Bodies of banded primary ore, assaying high in silver and gold, have been found in the lowest workings, 1000 ft. below the outcrop. As in the rest of the mine, the most valuable ore contains silver sulphide, with a small but important and constant percentage of gold. The ore at the Casados mines near the San José is said to be similarly banded.

The Cinco Minas fracture system is easily traceable northwest along the west side of the Santiago to the vicinity of the Santo Domingo vein-system. Here parallel productive veins are known, some of which have been worked for many years. The deposits are quartz, with silver sulphide containing gold, and are thick, robust bodies, sometimes 30 ft. across normal to the dip. The conditions in the Santo Domingo area have been somewhat complicated by faulting. The veins have been intruded by a dacite stock, entering from the east like the Cinco Minas intrusion, but of more recent age. The faulted blocks, of immense size, have been moved a considerable distance to the east, after which re-cementing and later mineralization of the broken and loosened masses have formed immense irregular deposits on the river side of the hill. Developments now in progress on neighboring prospects will later afford

interesting data bearing on this feature. The dacite stocks in general seem to antedate the veins; the rhyolite flows, on the contrary, seem to be of later date and to go across the veins. Such a flow in the Balbaneda area came up from south to north at about 45°, covered the Cinco Minas vein-system below the southern end of the properties, and aided in forming the rugged topography of that section. The flow occurred intermittently with basalt eruptions. Upon the inclined surface of the rhyolite are found perfect cooling-prisms of basalt, undisturbed since the date of their deposition.

Official maps and determinations claim the existence of slate and shale (*pizarra*) in this area. They are best shown at the mouth of the Balbaneda canyon in nearly vertical cliffs. The rock is blue-black, finely laminated, with numerous light hair-lines parallel to the lamination. It breaks and splits in a manner quite similar to shale, especially where the specimen is highly decomposed. The rock is not

Fig. 3. Tertiary Corrals Found near Cinco Minas.

shale, however, but flow-rhyolite belonging to the sheet just mentioned. It is of great extent, reaching from the Balbaneda through and beyond the San Mattias canyon and becoming massive in the latter arroyo. Both canyons have formed following the line of this flow, succeeded by erosion of the overlying basalts. At present the Balbaneda creek flows for most of its course between precipitous walls of rhyolite on the north and of basalt on the south: at the canyon mouth later disturbance of the flow has allowed the water to cut its way through the rhyolite.

On following the cliffs into the side gorges where decomposition has not been so active, the same laminated 'shales' are found, but represented by five-sided prisms of indisputably igneous origin: and by following still farther, whole cliffs of these cooling-prisms, exactly identical with the shale-like rock, but plentifully sprinkled with large phenocrysts of feldspar, may be seen. The succession affords most satisfactory opportunities for study. In addition crystalline aggregates of obsidian in quantity are associated with the rhyolite. The only sedimentaries observed here are the small and economically unimportant conglomerate beds already mentioned, and a few still smaller limestone beds of negligible area and a few inches in thickness, near the town of Hostotipaquillo. They belong to the low-level (probably Tertiary) period when all this section was submerged. To this period appear also to belong the interesting and quite modern corals shown in the photograph (Fig. 3). They occur in a small hill near Cinco Minas, on the surface, the whole hill being made up of them. They are the only fossils observed in the district.

The close relationship of the dacite intrusions to the ore deposits of the region cannot be better shown, in a way somewhat different from the conditions prevailing at Cinco Minas, than at a mine nearby. The original rich deposits here were entirely in the andesite, and were stoped to considerable depth over an unusual length. Recent exploratory work at depth below these workings has shown that this important deposit was not merely a cooling-crack in the andesite flow, but that like the others of importance, it is genetically related to a dacite intrusion. The latter, coming up from below as a stock, fractured the andesite sheet and was itself fractured. Mineral-bearing solutions circulating in the openings since the disturbance have formed a vein, low in metallic content in the dacite, rich in gold and silver in the andesite. The difference in alkalinity was evidently the determining factor in precipitation.

The recent age of the deposits in the vicinity is interestingly shown by the fact that at the bottom of the lowest working in one mine I found a piece of practically unaltered basalt, as part of the vein-filling of country-rock breccia. Thanks are due the management of Cinco Minas for permission to publish the notes regarding the general geological features of these deposits.

ONTARIO OUTPUT, JANUARY-JULY

Returns to the Bureau of Mines of Ontario show that the output of the metalliferous mines and works for the six months ended June 30, was as follows:

	Quantity.	Value.
Silver, oz.	12,804,992	$6,260,197
*Cobalt, tons	189	35,657
Copper, tons	4,634	660,497
Nickel, tons	9,339	2,005,660
Iron ore, tons	39,497	113,082
Pig iron, tons	221,718	3,540,688
Zinc ore, tons	576	5,000

*Only cobalt paid for included.

Shipments from silver mines aggregated 14,787 tons, of which 12,024 were ore and 2763 concentrate. The former averaged 814 oz. of silver per ton and the latter 1017 oz. Gowganda contributed 334 tons of ore containing 317,925 oz. of silver, and the Lake Superior district a small production, the remainder being from Cobalt proper. The production for the corresponding period of 1909 was 11,234,382 oz. of silver valued at $5,379,980. The nickel-copper mines of Sudbury turned out 9339 tons of nickel and 4634 tons of copper, as compared with 6027 of the former and 3741 of the latter for the same period last year, an increase of 52 and 42%, respectively. The production of pig iron as compared with the first six months of last year does not show a very large increase, the figures being 221,718 tons, having a value of $3,540,688, as against 211,583, valued at $3,197,759 in 1909.

Development and Operation of the Mining Law of New Zealand

By A. C. Veach

*New Zealand was formally made a portion of the British Empire in 1840, and in the same year the settlements at Wellington and Auckland were established. This colony was thus founded at a time when those in control of the colonial office in London were not in favor of reserving in deeds of grant any minerals, and this policy has been followed to this day. While it was separated in 1841 from New South Wales, of which it was initially made a dependency, the land laws and regulations in force in that State, including the imperial lands sale act of 1842, continued in force until 1846, when a new charter was issued. In the instructions under the first charter it was provided that (1) lands should be separated into "such as are supposed and such as are not supposed to contain valuable minerals;" (2) that mineral lands might be sold at auction, after due notice, at any price exceeding the minimum fixed for ordinary lands; and (3) that any land supposed to contain minerals might be leased for any term of years not exceeding 21 at a royalty of 15%. This sounded the keynote of the mineral-land policy that has been followed by New Zealand to this day. The administration has always endeavored to separate mineral from non-mineral lands, and the laws have always authorized the sale and leasing of such lands. The royalty was reduced in 1848 to one-fifteenth, and in 1850 the first separate mineral lease regulations were issued. New Zealand was, under the charter of 1846, divided into two provinces—each with its own lieutenant-governor and assembly, composed of a legislative council and a house of representatives. All the North Island, except a small area about Wellington, was included in the province of New Ulster, and all the remainder in the province of New Munster; the cities, Auckland and Wellington, were naturally the seats of government of the two provinces; in addition there was a general assembly for the whole colony. The mineral regulations of 1850, although appearing in the *New Ulster Gazette*, were apparently applicable to the whole colony, and while a waste lands occupation act was passed in 1849 for the province of New Ulster, the land regulations were generally the same for the whole colony.

At this time coal and copper were known in several parts of the colony. A copper mine had been opened on Kawau island on freehold land, acquired in the period previous to 1847, when no distinction was made between mineral and non-mineral lands, and a coal mine, which, like the Kawau mine, never proved of any value, had been opened at Nelson as early at 1842. How soon government leases were issued under the instruction and regulations cannot be determined, as most of the early government records were lost when the capitol was transferred from Auckland to Wellington. It appears, however, that leases were issued in 1852 for coal and copper in the vicinity of Nelson, presumably under the 1850 regulations. In the same year alluvial gold was discovered near Coromandel Harbor, and provisional regulations were at once issued. These, like the first Victorian and New South Wales regulations, related only to the digging of alluvial gold, and fixed the same fee of 30s. per month. The lands involved were native lands and were entered under special agreement with the natives; the government, in addition to paying a fixed sum to the natives, based on the number of miners, agreed to give the natives 2s. from the amount received for each miner's license. This goldfield did not prove of much importance and was for a time abandoned; the necessity for special gold mining laws, therefore, did not arise until some years later. Gold was found in Nelson in 1857, in sufficient quantities to cause some excitement, and as the field showed some evidence of permanency there resulted the goldfield act of 1858. This was largely based, as were succeeding goldfield enactments, on the Victorian statutes. However, it was not until 1861 that finds of sufficient importance to attract more than local attention were made. In that year large discoveries were made in Otago, and the first gold rush which affected people beyond the colony begun. In 1861 $3,750,000 worth of gold was produced in the field, and this rose to $7,500,000 the succeeding year, and to almost $12,000,000 in 1863. The excitement here had hardly begun to subside when considerable finds were made in Marlborough, and in 1865 the famous West Coast goldfields were discovered. About this time rich lodes were found in the Coromandel fields and the importance of New Zealand as a gold-producing region firmly established. At first the work was conducted wholly on the basis of miners' rights and claims, but in October, 1859, an application was made for a gold mining lease in Nelson, and in 1860 numerous applications were filed. As the early period of alluvial digging passed, more and more developments were undertaken on leases and the miners' right claim was gradually restricted until today only alluvial ground can be held under this form of tenure; all reef or lode development must be undertaken under license or lease.

In 1859 the coalfield near the Clutha river, in Otago, was reserved and mining leases issued. In 1862 reserves were made in Nelson covering the high-grade bituminous coals of that region. Coal leases were at once issued and the development of this, the most important coalfield in the colony, was begun. Coal was not exported in any quantities until 1867. Mines have been opened gradually in many parts of the State, but except in the West Coast coalfield the coal is of a sub-bituminous or lignitic character. The developments of minerals other than gold and coal have thus far not proved of much importance, with the exception of the fossil resin, Kauri gum. This substance was first dug in 1853, and the total production to December 31, 1906, had a value of £13,443,017.

*Abstract from 'Report on Mining Laws of Australia and New Zealand.' Government Printer, Washington, 1910.

The mining law for coal and minerals other than gold was for many years interwoven with the land regulations of the provinces. Under the constitution act of 1852 New Zealand was in 1853 divided into six provinces; the two old provinces of New Munster and New Ulster were abolished and the new provinces were named, Auckland, New Plymouth, Wellington, Nelson, Canterbury, and Otago. This number was afterward increased to 10 by the formation of the provinces of Hawkes Bay, Marlborough, Southland, and Westland, and the province of New Plymouth was reorganized and renamed Taranaki. Each of these provinces had a superintendent and a provincial council, and there was a governor and general assembly for the whole colony. Each province had its own land laws, and the administration of these laws rested wholly with the local officials. Although these provinces were abolished in 1875 and a central land office created in 1877, the local administration by land boards has continued to this day, and until 1892 separate provisions were made under the lands act for several of the old provincial areas which had been renamed land districts. In 1892 the lands acts were made uniform for the whole colony. The local land boards are still, for the most part, charged with the classification of the lands; in this they are assisted by a trained permanent corps of land surveyors, appointed only after rigid examinations. This force is under one surveyor-general, who is a highly trained officer, comparable to the head of the U. S. Coast and Geodetic Survey. The New Zealand land office is strong where the American is weakest.

It may be noted in passing that the striking retention of the mineral lands, which has characterized the history of this colony has been effected not by a single department but (for almost twenty-five years, or during the time of the provincial administration), by 10 entirely independent bodies. That they all adopted the same policy but adds to the impressive character of the results and clearly indicates a strong and general public feeling. All this happened long before any Labor or Progressive party was even thought of in New Zealand, and the matter is to be regarded not as a socialistic propaganda but as a simple business judgment. There was throughout this period always the provision for sale, and that practically no known mineral land was sold is clearly a most convincing indorsement of the success and practicability of government mineral leasehold. Had it been found desirable or necessary to sell the freehold of mines in order to promote mining industry and the general welfare of the region there can be no question but that the minerals would have been sold.

In some cases these provincial regulations also touched gold mining. In several of the early goldfields acts no rental was fixed, and this rental was determined in each province. The Nelson waste-lands act of 1863 provided that gold leases should be issued at a rental of 10% of the value of the land involved, but that no land should be valued at less than £10 per acre. It further provided that "before a lease is granted the land may be offered for sale at public auction at the upset price on which the rent is charged." This is the only specific provision which has ever been made in Australasia for the sale of known auriferous lands.

Although a general mining act was passed in 1877, provisions regarding mineral leases continued to be incorporated in the lands acts for several years. Special acts were from time to time passed with reference to certain coalfields, and in 1886 the coal-mining law was entirely separated from the other mining law. Scarcely a session of parliament has passed without the enactment of an amending mining bill, so that taken all in all the number of acts which have been passed in New Zealand containing provisions regarding mining is very large. The existing law as to minerals other than coal and Kauri gum is found in the mining act of 1905.

The result of the test of government mineral leasehold in New Zealand affords a most conclusive demonstration of the soundness, practicability, and economic value of this form of tenure. For sixty years this State has provided for the sale and leasing of mineral lands, and yet practically no known mineral lands have been sold—all have been leased. For forty-two years in one part of the State or another the lands comprised in mineral leases could be put up for sale at public auction at the request of the lessee after three years' development work, and for seventeen years the lessee could demand such a sale as a right, and yet an entirely negligible quantity of land was sold in this way. This result has been attained not by arbitrary or despotic means, but in a freedom-loving English-speaking country, a country which within the past year has conclusively demonstrated that it cared not for abstract doctrines, but only for results. It cannot be considered as the result of any socialistic or labor agitation, for during the first forty-four years the dominant political party was the Conservative; only in 1891 did the Progressive and Labor Party become of importance, and it has done little more in connection with the mining law than continue the principles already established. Had the policy of mineral leasehold not proved entirely satisfactory, the sale of mineral lands would undoubtedly have resulted, as is conclusively shown by the action of the State in regard to perpetual agricultural leases. One of the early acts of the Progressive or Labor Party was to provide for a 999-year lease for agricultural holdings. This was in response to the cry for the non-alienation of land, but in providing for this form of tenure the settler was allowed to select between it and freehold. Under these conditions more land was taken up under perpetual lease than under forms of disposal leading to freehold, and the advocates of this plan rejoiced. However, after a time the holders of perpetual leases desired the freehold, and as a result of their demands a law was passed the last session of Parliament abolishing 999-year leases and permitting the holders of such leases to convert to freehold. Not only is there now no demand for the freehold of minerals, but the mining men are practically a unit in regard to government leasehold as better for mining industry than freehold

Summer Travel in Mexico

By J. A. MacDonald

I have just been discussing mining affairs in Mexico with a young engineer who was there last summer, and he concluded by saying that he would not go there again in the rainy season for the best mine in the Republic. The sun glared on him, the rain wet him, the mosquitoes bit him, the natives would not speak English to him, he did not like the way they fed him, he could not find a mine, and it was all very distressful. I think it is all a matter of temperament. It is very doubtful if that man will ever find a mine, make a mine, or operate one successfully. It is true there are some vicissitudes there in the rainy season, but compared with the blasts and blizzards we often have to endure in the northern hills, a trip there would seem to me a veritable honeymoon. Nine winters ago, some four or five thousand men went up to Thunder Mountain, Idaho, through the deep snows of that country, with packs on their backs, and not one made a valuable discovery. Many left their bones in the wilderness. I never saw so many sick men outside of a hospital as were scattered along that trail. I believe the wood-ticks that infested the trees and brush caused much of the sickness, apart from the hardship and exposure. Notwithstanding all this the most of them would immediately start out again under the same incentive. Among mining men 'the lust for gold' is not so strong as is the joy of conquest, the spirit of adventure; the spirit that scorns all danger, all obstacles to attain an end. To those who have not traveled over the mountains of Mexico in the summer season, some details of such a journey may prove interesting, possibly of some value.

I took with me a folding cot, blankets, shelter tent, mosquito netting, oilskin jacket and pants, and a little box of medicines, containing quinine, seidlitz powders, ammonia, permanganate of potassium, carbolic acid, borax, vasaline, witchhazel, and some ipecac, which is a specific for dysentary in hot climates. There also was a package of indigo for snake bite. I had room for a blow-pipe outfit in the same box. Of the medicines, I only had occasion to use the ammonia and permanganate, for the bites and stings of insects, and once I found the carbolic acid effectual when the other drugs failed. I was able to alleviate many ills among the natives with these simple remedies. The people have knowledge of many valuable roots and herbs in their own country, but are usually too improvident and indifferent to gather them before they are needed—that is part of 'the white man's burden.' There is an Indian in the Fuerte valley who has a remedy for hydrophobia that has never failed in any case he has been called on to treat. That terrible disease is prevalent there, originating with the small pole-cat and being communicated to the coyotes and other animals. Because of some superstition this Indian will not disclose his remedy.

Last summer I had to examine a property in the southwestern part of Chihuahua, in the District of Chinipas. I took the evening train from Los Angeles and arrived at San Blas Junction, Sinaloa, after a ride of 49 hours. There was nothing to mar the pleasure of the journey, though it was very hot going through Yuma; hotter than in Los Angeles. They said the thermometer registered 118° in the shade the day previous, "but then it was dry heat" and they did not mind it much. If they ever get a wet heat! I remained at San Blas over night and took the 11 o'clock train the next morning for Fuerte, on the K. C. M. & O. railroad. The station at Fuerte is five miles from the town. Some of the land-holders there were extravagant in their demands of the railroad company. Hence this gap.

Fuerte is a picturesque little town of some 5000 inhabitants, situated on the river of the same name. There are three good hotels that furnish bed and

Part of Northwestern Mexico.

board for ₱2. I stopped at the Cosmopolita, where I met some old friends. The next day I secured two mules; one to ride and the other to pack my bedding and grip to Choix, as it is more convenient to outfit there for a journey into the mountains. The distance is 45 miles over a good wagon-road. I paid ₱7 for the use of the mules and for a boy to bring them back.

We left town at 4 o'clock in the afternoon to avoid the heat of the day. About two hours after, a violent thunder storm came up. I put on my oilskin suit and let it pelt away. The lightning flashed and quivered around and above us, and at every crash of thunder overhead it seemed another cloudburst. It was a furious war of the elements, but it surely made the corn rejoice. We jogged along till we came to Aguajito, a small pueblo about 25 miles from Fuerte. Here we stopped for a few hours' rest. The family was sleeping on the porch. Don Luis, the master of the house, insisted on my taking his bed, though I had my own. He never saw me before or after, and that act of courtesy was characteristic of those people wherever I went. He prob-

ably slept on a mat the remainder of the night. We slept about four hours, it seemed fifteen minutes, and were off again at the *madrugada* (daybreak). We arrived at Choix at 8 o'clock, in time for breakfast. Choix is a small town of about 1500 inhabitants, and situated on the west bank of the Choix river. Here, as at Fuerte, the water for domestic use is brought to the house in leather sacks, swung on the backs of burros. The sacks are filled by driving the burro far enough into the river to fill the sack. A plug is withdrawn from a hole in the bottom and the water allowed to flow in. The country hereabout is chiefly underlain by granite showing considerable feldspar. There are low hills at intervals. Low-grade placers have been worked to some extent by the natives along the Choix river. None of them, I believe, can be considered worthy of attention. I could not learn of any mine south of the Fuerte river that was being worked at a profit. East of the Choix there is a range of mountains with mineral veins that may prove valuable. Twelve miles east is a large deposit of low-grade copper ore, in a rhyolite dike close to the river. It is estimated that six million tons of ore are exposed. The ore consists of oxides and carbonates of iron and copper, with a little gold. It is called the Mozamique mine and is owned by Americans. Some time ago I found rich gold quartz near the head of the Choix river, but never have had time to seek its source. At Choix, Vega & Sons have a complete assortment of goods for the home, camp, or mine. I purchased a cooking outfit and supplies from them at prices but little higher than at Nogales. As it is not expedient to purchase mules for a short trip, I engaged three at the rate of ₱1 per day, and a mozo or guide at the same rate. Good mules accustomed to the mountain trails can be bought for from $50 to $75.

In traveling through the mountains in this country the mozo is almost a necessity. Using ordinary precaution in securing them, one will find them to be loyal and extremely honest. They are expert packers, know the best trails and fords, the best places to camp, and where the best pasturage may be found on the road. While you ride they trot along on foot behind, tireless, silent, and vigilant; every now and then tightening up or adjusting the pack or chasing the vagrant mule back to the trail from which he has wandered. When evening comes they care for the animals and make themselves generally useful.

Making a late start the first day I stopped at Nacimiento, some fifteen miles from Choix and camped at the home of Jose Barfuson, an old German, 'the Sage of Nacimiento.' He has been in Mexico since the Civil War in the United States, having fought under General Grant. He is full of reminiscences. I spent a pleasant evening under his hospitable roof and got away early the next morning, reaching the raging Fuerte about noon. The water was about ten feet higher than normal. We hailed the boatmen at the ferry near the mouth of La Reforma canyon; they came over with a good sized boat, into which we loaded our outfit. Having stripped the mules, we led them astern with ropes, and, rowing the boat with all our might, we crossed in safety. I would not attempt it again while the river was so high. It would have been more prudent to wait a day or two and not run the risk of losing the mules. The river sometimes rises thirty feet above low-water mark. It is destined to furnish great water-power and to supply water to irrigate a large territory. After a light lunch we entered La Reforma canyon. We were in a great mineral region, one to delight the eye and sense of the miner. The mountains rise in rugged grandeur each side of the narrow chasm to a height of two or three thousand feet. At this season a stream fifteen or twenty feet wide and a foot deep flows down the canyon. We noticed the masses of igneous rocks, covering the granite base, and reaching the tops of the highest peaks. Far up where the slope of the mountain will permit, patches of cultivated ground may be seen. Along the margin of the stream many *higueras*, a species of fig tree, grow luxuriantly. They resemble a cottonwood. My mozo said that they produce a fruit which is palatable and nourishing. Occasionally we saw a *guajilote* tree all abloom with big purple flowers, something like those of the oleander in form and color. Where the soil is favorable fine specimens of the sycamore grow, and always the thorny cactus and mesquite. It is remarkable the number of trees that have thorns in this country, even on their trunks. No doubt it is a wise provision of Nature for their protection. If man would take the hint and prevent forest fires it would accrue to his advantage.

The trail follows the bottom of the canyon, and when that becomes too rough it climbs the sides of the hills. Two slender waterfalls descend the east side of the chasm from a great height. The water is pure and refreshing. The water below is poisonous in the dry season when the flow is scanty, being heavily impregnated with copper from the veins and mines in the district. There is a copper mine at the head of the canyon, called the Bahneracic, that was worked extensively during the French occupation. It might be profitable to use a precipitant here for the copper. Many veins crop out on either side of the arroyo, and at least one showed a good percentage of copper. It was about six feet wide and was heavy with bornite. The pay-streak occupied about one-third the width of the vein, and the bornite lay in bands and convolutions where the stream had stripped it bare. Far up on the mountain I could see old workings on what appeared to be the same vein. I could learn nothing of its history except that it was open to denouncement. There are squatters occupying every available spot along the arroyo where a bit of ground can be cultivated.

About 4 o'clock we reached the home of the Garcia family, where I am acquainted. The grandmother is a fine old lady with the dignity and mien you might imagine graced the mother of a Diaz or Cortez. The next morning we took the trail leaving the noted Lluvia de Oro mine a few miles to the southeast. For centuries that great deposit lay neglected, staring out from the face of a limestone cliff, while Mexican and Spaniard passed and repassed it un-

heeding. The Indians knew its merit, but kept the secret well, till one of them in a drunken orgy babbled about it, not knowing that Espiridion, a Mexican, listening, knew his tongue. It came into the possession of Americans. At first under the capable management of Mr. Underwood, who was ably assisted by Tom Smith, it became a famous producer. They shipped ore from this mine that ran 60 oz. in gold and 1100 oz. in silver per ton. Later, under various managements, it has had a checkered career, but like a good man it cannot be kept down. I learn that now they have a competent engineer in charge. It has been the scandal of two nations.

I have reason to believe that a number of good veins will be found within a radius of six miles of this property. There is a 'lost mine' in this vicinity, called the 'Gloria Pan.' They have the records of it in the archives of the City of Mexico. There is the Gloria Pan mountain and Gloria Pan pass, named after it, while on the hillside remains the slag pile from the ancient furnace where the ore was treated; but the mine itself cannot be found. The Indians know where it is, but will not tell. A good prospector would probably find it in a few weeks' search.

Toward the head of the canyon we reached a point called Tule, from which we took an arroyo to the east that brought us to the little camp called San Francisco. Here I met my friend, Jim Paul, who was to guide me to the property I had to examine. One of the animals I engaged was unfit for the journey farther, and I sent it back to the owner. Jim had a good saddle mule and a pack-horse, and with them we made an early start the next day. Climbing up a steep trail we reached a point that commands a magnificent view; the freshness and glory of a beautiful morning were on the hills. To the horizon on all sides, undulated one vast sea of corrugated stone. Only in the 'Great San Juan' or in the wilds of Idaho have I seen such evidence of the mighty forces of Nature. These scenes never pall on the senses of the mountaineer, whatever may be his fatigues or difficulties.

We followed the trail along sharp ridges, down through steep gorges, across streams and up again, over rough trails and smooth trails, sometimes so bad we had to stop and make repairs. The sure-footed little mules picked their steps with rare sagacity. The air was fragrant with the perfume of many flowers. The mocking-bird and his cousin, the *cuitaceche*, more musical, charmed the ear with their melody. The parrots in flocks chattered about us; occasionally the *cuiche*, a fine game bird, started up from some shady dell as we passed. This bird crossed with the domestic fowl makes a great fighter; the ordinary game-cock has no show with him, as he fights in the air. At intervals by the wayside we noted a lonely grave marked by a cross and a cairn of stones. The wandering Scot may here recall a feature of his native hills.

About noon we passed through Becerra's ranch at Huachara, where there are some hot springs. There is considerable limestone seamed with veins in this district, but as we were pressed for time we could only look at it with longing eyes. We got some grain for the animals at the ranch house and pushed on to a vacant cheese factory, where we camped for the night. It rained heavily as we neared this point, but we managed to start a fire and cook supper under shelter. About dark Jim was stung by a scorpion on the finger as he came through the fence of the corral. The fiery lance of the little demon burned like a red-hot iron. I applied some ammonia, which relieved the pain, but his finger remained numb for several weeks. We were tormented with 'jiggers' which cover the wet leaves at this season. They make their way through the clothing, and even through shoes, burrowing into the flesh and causing intense itching. We did not mind them much during the day while we were occupied, but at night when we got between the blankets the annoyance became intolerable. We bathed from head to foot with a solution of permanganate, which soothed us to sleep and proved an efficient antidote. Later I found coal-oil would answer the purpose quite as well. The jigger dies in about twenty-four hours without any application—but he dies hard.

Our course the next morning was nearly due north; the trail was somewhat obscure at first, but Jim soon found it, and we went on at a good rate till we came to a sharp declivity where Jim's pack-horse lost his footing, fell down the mountain over the jagged rocks, and was killed. We put the pack on one of the saddle mules and took turns riding after that. We reached the Cayereche river that evening. The water was so high we could not cross, so we camped at the house of an Indian near the ford for a couple of days. He had a little boy not old enough to talk, yet he could sing, and kept up a chant much of the time. The little fellow was very interesting. These people are of a happy temperament, but the poor women always seemed to me to have a look of inexpressible sadness in the depths of their eyes that is pathetic. The men seem to treat them with kindness, but their life is one of hopeless drudgery from early dawn to close of day, and the natural cheerfulness of their disposition is blighted by the most abject poverty.

We employed our time here in prospecting, but without finding anything that appealed to us. The appearances are much better on the other side of the river, where there are some big dikes decomposed and heavily stained with iron. When we finally crossed over we tested some of them near the trail and got fine colors of gold, but nothing that looked like pay. In two days' travel from this point we arrived at the property I came to examine. I got the necessary data and took samples which I had assayed at the laboratory of the La Plata mine, known locally as the Santa Barbara mine. Mr. Walton, the metallurgist in charge at the mill, showed us every courtesy. They have a good plant of machinery here, adapted to concentration and cyanidation. Power is developed from the Septentrion river, which crosses the vein worked. The lower adit was driven in 900 ft. on the vein without a break in the ore. The pay-streak varies from 12 in. to 12 ft. in width and the face of the adit was still in ore at a depth of 800 ft. below the surface.

The average value of the ore is said to be about $100 per ton, mostly silver. Crispino Guerra, the Mexican who found the mine, never realized a dollar from it. He was too poor to denounce it, and those to whom he showed it proved ungrateful. I was told it was purchased by the present owners under a bond for $750,000. Guerra is now herding goats in the neighborhood.

I saw some good looking prospects in that district. Some of them showed ruby silver, but silver sulphide and chloride prevailed. A few miles down the river from where we camped, I noticed that the formation was greatly disturbed. I went to investigate, and found evidence of an old crater, about one-fourth of which remained; the rest of it had been eroded and had tumbled into the stream below. About 100 ft. north of the rim, running at a tangent, there was a good vein with a six-inch streak of quartz that yielded $7.25 in gold per ton. There is an abundance of game hereabout, deer, turkey, wild hogs, and flocks of wild ducks on the river. Much as I would have liked to remain in the country, circumstances made it imperative for me to return without delay, so bidding farewell to the many pleasant acquaintances we had made, Americans and Mexicans, we started homeward. Our return was but a repetition of our journey inward.

During all our travels we only saw three snakes, one of which we got near enough to kill. We also killed a huge gila monster. They seem to grow much larger here than in Arizona. The mosquitoes and jiggers gave us the most annoyance. Whenever we left the trails our progress was slow and difficult, as the tangle of vines and underbrush grows exceedingly dense. I carried a pedometer and found we could only make about a mile an hour, and even then, when not wet with rain or dew, we were bathed in perspiration. In the winter season it is entirely different and much more agreeable, besides, a better view of the surface can be obtained.

I have often wished when going through some great mining camp like Butte or Cripple Creek, that I might once get into a mineral region that was not plastered over with locations, and here in the Sierras of Mexico was the first time such an opportunity came to me. I knew a reliable man who in a journey of two months made four valuable discoveries, and had little time to prospect. For a hundred miles or more, north of the Fuerte river, approximating the course of the 'Stillwell' railroad (K. C. M. & O.) is a great mineral zone, where the conditions seem ideal for good mines. Andesite is the prevailing rock of the country, and this is intruded by dikes of rhyolite, diorite, basalt, and other igneous rocks, with limestone at intervals. Granite appears rarely. The rocks are faulted, folded, fissured, and traversed by many veins. There is much decomposition and chemical action evident. The erosion has been great and the deep gorges with bare walls afford easy prospecting to the practised eye. The laboratory of Nature has been prolific in the distribution of her treasures in these mountains, both as to quantity and quality. Nearly every metal as well as gems and precious stones are found scattered through these hills. Coal and oil are abundant, though but slightly developed. Of iron there is scarcely a limit. In Sinaloa there are many fine tracts of timber and not a saw-mill in the State. Owing to certain wind currents the time of the rainy season is the reverse of that in California. From June till October the rain falls at uncertain intervals; not always when it will do the most good. In the northern States there is no sure crop without irrigation. In the mountains there is little ground available for cultivation. The slopes are so steep and the gorges so narrow that only rare spots can be tilled, and these are fully utilized. It is essentially a mining country, and as such it has no rival. Its resources are infinite.

These notes on agricultural conditions only refer to certain portions of the Republic. In some of the southern States from 80 to 160 inches of rain falls annually; in that section all tropical vegetation flourishes. In the north and northwest States there is a scarcity of food much of the time and many of the people are in a state of destitution. Whatever their condition may be they are always kindly, courteous, and amiable in a rare degree. Too often they are improvident, shiftless, and lacking in application—prone to emulate the lily of the field that toils not—but withal they are exceedingly human. I speak of these traits because some who deal with them are unable to modify the standard of action to which they are accustomed in Boston or Oklahoma. Under the wise and beneficent rule of the present government the Mexicans are making rapid progress. Education is compulsory and eagerly sought in the cities and villages of any size. In remote districts schools are not yet possible, but in due time these will be reached. Nearly one-sixth of the population speak the Indian tongue only, but order prevails among them. There has been a great deal written about tyranny and arbitrary rule down there and there may be instances of it. I have discussed political matters with Mexican citizens and officials and they were as free to criticize their government as any radical here in the States. More than that, I know an official who went down to the City of Mexico to remonstrate with the President himself about an election that recently took place. He came back smiling and not in the least disfigured. There are only two rulers on earth anyway who are pre-eminent, and Diaz is one of them. The laws are generally just and no more selfish than our own. In some cases they are more liberal. The intelligent foreigner who goes there will adapt himself to his environment. If he is unreasonable and critical he will have plenty of grief and had better stay at home. Wise statesmen of all nations do well to encourage foreigners who can add to the prosperity of their country. They soon become as good citizens as any, and this is recognized in Mexico.

In these brief notes I have referred to a narrow strip of country, a mere thread in a web. There are two great ranges coursing southeast for nearly two thousand miles, besides the isolated peaks that are highly mineralized and much of this territory has never been prospected.

Discussion

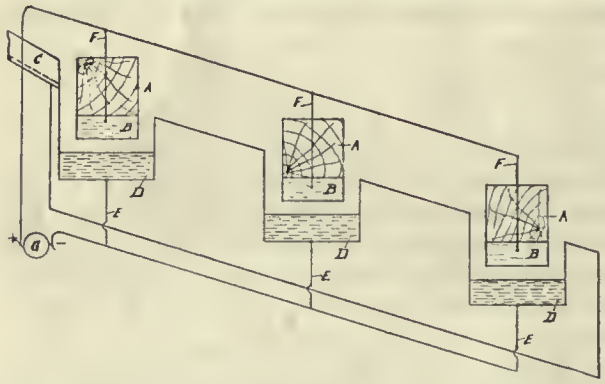
Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A Cyanide Problem

The Editor:

Sir—In your issue of August 13 appears a communication signed 'Mine Owner,' from Tucson, Arizone, in which reference is made to quartz gangue, abounding in pyrite, with small amounts of galena, blende, and chaleopyrite, the value being chiefly in gold, which may be panned; the further statement follows that after amalgamation and cyanidation the tailing was of about one-half the value of the head; your correspondent states that silver is also present in a complex antimonial compound, and attributes the low extraction to the presenee of antimony, and desires to know if there is any remedy besides roasting.

I would suggest that a remedy may be found in the use of the electrolytic sodium-mercury cell for



Three electrolytic sodium-mercury cells, forming a portion of electrolytic amalgamating sluice; longitudinal sectional view. A, baffles for deflecting gangue on mercury surface; B, graphite electrode (anode); F, positive connection with generator, G; D, mercury connected as cathode with negative lead, E; C, launder delivering pulp, water, and salt solution.

amalgamation in which a series of mercury cells or riffles (Hungarian mercury wells) are arranged in the form of an electrolytic amalgamating sluice, the mercury being excited by a low voltage current (five to ten volts) of high amperage (twenty to thirty amperes per square foot of mercury surfaee). When such a device is adjusted to the existing conditions, it has been found that all gold and silver in a metallic state not encased readily amalgamates. Pulp and slime are simply passed over the device and the metals are automatically extracted in the form of amalgam. The construction of the apparatus prevents any blanketing of the mercury and fouling or flouring is impossible. To obtain these results in the electrolytic mercury cell a definite amount of salt solution is fed into the water passing over the sluice; sodium amalgam is formed and any required strength is constantly and automatically maintained. The construction of the mercury sluice is illustrated in the accompanying design, which represents a longitudinal section of three cells. In such a device, properly constructed and adjusted, all free gold and silver, regardless of the presence of sulphur, arsenic, copper, antimony, or other refractory elements, will readily amalgamate while the gangue is passing over three or four lineal feet of excited mercury surface; such a device has a capacity three times as great as a mill plate of the same width.

To determine the amount of free metal in ore at any given mesh, assay a sample; then treat a similar sample with strong sodium amalgam. The sodium amalgam should be strong enough to amalgamate copper wire instantly. After agitating for twenty minutes carefully draw off the water, pulp, and slime, evaporate and again assay; the difference between these assays shows the free gold present, which may be extracted by a series of electrolytic cells. As only a low voltage current is needed for the electric amalgamator, the cost of operating such a device is trifling; a five horse-power generator will furnish current to treat the product of a 40-stamp mill. I might add that these statements are based on the results of scores of demonstrations, and there is ample evidence that the electrolytic sodium-mercury cell will extract all released gold regardless of the physical or chemical conditions of the gold or associated elements. The basic patents on electrolytic amalgamation have all expired.

ELMER ELLSWORTH CAREY.

The Weight of Learning

The Editor:

Sir—The worst offender among manufacturers of cumbrous books has been discovered and I take pleasure in holding IT up to public contumely. As it is a bureau, and as it has reformed to a degree, I feel sure that it will not be offended.

In 1894 and again in 1904 the Bureau of American Republics issued a valuable publication in two volumes, entitled 'Commercial Nomenclature.' The books contain parallel columns of English, Spanish, and Portuguese names of commodities "upon which duties are levied." As duties are levied, in one American republic or another, upon practically everything portable, the list may be said to be complete. Over 50,000 names of things are listed, including everything from absinthe to zoötic (hydrocyanic) acid. Every engineer who comes in contact with Latin-Americans and Americans will find it useful. But the desk can be used for nothing else if even one of the volumes is in use! Why should each book have been made 12 by 15 by 2 in. with a combined weight of 18 pounds and some ounces? The pica type is clear, but such large type is not required or even desirable in a book of reference. The board bindings are heavy. Each page is provided with a blank space 7 by 3.5 in. solely for the use of the reader for 'remarks'! This total 'remarkable' area exceeds **250 square feet** of useless white paper. A careful comparison of these volumes with Kent's 'Mechanical Engineers' Pocket-Book' shows that the text in the two could be accommodated comfortably in a volume of the size of the latter, if similar paper and type were used. The cost of manufacture would

not be much greater while the work would be made available for a greatly increased circle of readers.

The edition of 1908 is much reduced in size, being issued in one volume 12 by 9 by 1.5 in. weighing 5 lb. 10 oz., a reduction to one-third the weight of the first edition. That is a good start, but the next edition should weigh only one-quarter of the present edition, or 23 oz., the weight of Kent's book. Besides the book containing the English words in the first column, are two other books to make the complete set, containing the Spanish and the Portuguese first, respectively. The three deserve a place on the shelf of any one who has to do with buying or selling between the American Republics, but when taken from the shelf must be sent by freight.

Milwaukee, Wisconsin, August 20.

A Johannesburg Landmark

The Editor:

Sir—I send you with this a correct view of the 'Corner House,' at Johannesburg, in the course of construction. The picture printed in your issue of July 23, by some means, was reversed. The building was on one of the landmarks of the city when

'Corner House' Central Administration Bdg , Johannesburg.

erected in 1904. Since then a number of large structures, the Stock Exchange, Carlton Hotel, and Barnato Bros.' building in particular, have been erected. The intimate relations of the 'Corner House' to the mining industry will perhaps warrant publication of this picture.

Standardization of English

The Editor:

Sir—It is refreshing to read an article like that of Mr. Rickard's, 'Standardization of English in Technical Literature,' in your issue of August 20. Engineers, both mining and metallurgical, are apt to become careless in their technical writing. "Remember the Reader" is the true 'key-note' of all literature, and should be especially so of all technical writing. Mr. Rickard objects to the use of colloquial words and local terms. I am obliged to accuse him of this error. We all know that Mr. Rickard comes from that sturdy stock we know as Cornishmen, and the world has not produced any better practical or technical miners. Every mining man is familiar with the 'lingo' of 'Cousin Jack.' On page 233, line 5, Mr. Rickard says, "There be those that write," etc. While I shall not discuss the actual rhetorical error (?) of the word **be**, it certainly cannot be denied that it is decidedly colloquial and local. Neither can Mr. Rickard hide behind the mention he makes of the discussion between Napier and Macaulay.

I think this should not **be**, really it must not **be**, and I sincerely hope will not raise any **be(e)s**.

C. O'BRIEN.

San Francisco, August 24.

Poetry and Metallurgy

The Editor:

Sir—Your Fiftieth Anniversary Number was most readable. In connection with that poem entitled 'Malgamatin' it may interest your readers to know that it was written one lunch hour by D. Doolette, then gaining experience in the sulphide mill of the Great Boulder mine here. It is very true, as all dry-crushing and roasting men know of such troubles. Another bit of verse, entitled 'The Love Song of the Metallurgist,' and written by Mr. Vesey, appeared in the *Sydney Bulletin* a few weeks ago. It refers in the main to Broken Hill. I quote one stanza:

"Oh, come where the cyanides silently flow,
And the carbonates droop o'er the sulphides below;
Where the rays of potassium lie white on the hill,
And the song of the silicate never is still.
Come, oh come!
And partake of some
Peroxide of soda and urani-um.

While alcohol's liquid at 30 degrees,
And no chemical change can affect manganese;
While alkalis flourish and acids are free,
My heart shall be constant, sweet chloride, to thee.
Yes to thee—
Chloride-dum-dee—
Zinc, borax and bismuth and $HO + C$."

METTALURGIST.

Kalgoorlie, Western Australia, July 23.

Calculating Niter in Crucible Charges

The Editor:

Sir—In an article, 'Analytic Work at Copper Queen Smelter,' appearing in your publication of July 30, page 147, a method for calculating niter in the crucible assay is discussed. It is that given in text-books and most published niter charges. In its condensed form $\frac{5W-20}{4.5} = X$ gm. of niter, where W equals the weight of lead reduced in the preliminary fusion. Why do we never see in print and seldom used this expression in its simplified form, $\frac{W-4}{0.9} = X$ gm. of niter? The result is the same.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A convenient size for specimens to be studied by the aid of a hand lens is 4 by 2½ by 1½ inches.

Hydraulic strippers have been brought into use by a number of quarries where the overburden is now being removed.

Diamond-drills are often used to determine the nature of the ground on which dams are to be constructed if sufficient data cannot be obtained from the outcropping rocks.

The best asbestos yet found in the United States occurs near the bottom of the Grand Canyon of Arizona. The quality of the asbestos is exceptional, but its situation in a reservation precludes its being worked.

A thick tempering oil, such as lard or whale, should be used in tempering chrome-vanadium spring steel; paraffine and other light oils should not be used. The bath should be kept as cool as possible, preferably by water circulating in pipes.

Electric sparking devices have been placed in one of the long tunnels of the Los Angeles aqueduct which is driven through oil-bearing strata so that any accumulations of gas may be ignited before they attain size enough to cause an explosion that would endanger the men or the work.

Fluorspar is prepared for the market by washing, crushing, and separating it from other minerals, after which it is ground for the finer trades. For foundry and steel making use it is sold unground as 'lump' or 'gravel' spar, in grades depending on color and degree of admixture of silica.

Continuous bucket elevators are those where the buckets are placed as close together as possible. This arrangement possesses the following advantages: the material may be fed directly in the buckets without striking the belt and wearing it out, the elevator requires no boot, and a greatly increased capacity is secured.

Compressed air in the foundry serves many uses: it operates molding machines, air-hoists, either independent or in combination with jib cranes, sand sifters, rammers, chipping hammers, and sand-blast for cleaning casting, pushes core oven cars into and out of the ovens, and promotes combustion in melting furnaces.

A valid appropriation of the water of a spring situated on a mining claim cannot be made without the consent of the owner of the claim. If the claim has been abandoned or forfeited there is nothing to prevent an appropriation of the water being made. If the water from the spring runs out and down a well-defined water course, it may be appropriated outside of the boundaries of the mining claim if no other prior rights have been acquired.

Briquetting tests conducted by the United States Geological Survey consisted of (1) the manufacture of briquettes to determine the adaptability of different coals to the process and the merits of different binding materials; (2) physical tests to establish the fitness of the briquettes to withstand weathering, transportation, and handling; (3) steaming tests to prove the calorific value of the briquettes in boilers of different types used by the Government, and, by comparison with the raw coals, the benefits to be derived from briquetting.

The mining law authorizes a junior locator to lay out the lines of his location so that the end of the junior claim laps over a senior location. The conflict area would belong to the senior claim. If the owner of the senior location subsequently draws in the boundaries of his claim so as to exclude the conflict area from the senior claim, the junior locator must amend his location and specifically include this area in his amended claim. If he does not amend his location, the area originally in conflict would revert to the public domain and be open to location. The junior claim would still be valid to the extent of the original area outside of the conflict.

Exports of iron and steel manufactures from the United States in the past fifteen years exceeded in value the corresponding imports by $1,400,000,000. In the fifteen years immediately preceding, on the other hand, imports exceeded exports by $300,000,000. According to the following figures published by the Bureau of Statistics of the Department of Commerce and Labor, the excess in value of exports over imports of iron and steel manufactures in the last 10 years is more than 2½ times the excess of imports over exports in the preceding 40 years:

Iron and steel manufactures.	40 years, 1861-1900.	10 years, 1900-1910.
Imports	$1,409,000,000	$307,000,000
Exports	973,000,000	1,411,000,000
Difference	$436,000,000	$1,104,000,000

A 235-mile natural gas line is being built for the Arkansas Natural Gas Co. from the Caddo Parish, La., gasfields to Little Rock, Ark. There will be several branches to supply cities on the way. The diameters of pipe are 12 in., 16 in., and 18 in.; there is one 20-mile stretch where a double line of 12-in. pipe is used. The line is to be constructed of plain end pipe connected by rubber-packed couplings, with the exception of five miles near Tupelo Springs, Ark., which will be constructed of screw-end pipe. The reason for the screw-end pipe is that a compressing station of three 1200-hp. units will be built at Tupelo Springs. Up to this point, a distance of 127 miles, the gas will be carried by the pressure at the wells, which varies from 465 lb. in the upper sands to 1000 lb. in the lower sands. Possibly two compressors may be installed near Vivian, which is in the gasfield. The main line will be from 2 ft. to 30 in. below the surface of the ground.

Special Correspondence

LONDON

Otavi and Tsumeb Mines. — Mount Morgan Report. — Robinson Deep.—Treasury Mine.

The Otavi and Tsumeb mines in German Southwest Africa are interesting ventures controlled in Berlin. The ore is rich and consists of a mixture of copper and lead sulphides. The higher grade is exported to Germany and the remainder smelted on the spot yielding metallic lead and a lead-copper matte. In spite of the low price of copper and the increased cost of mining, the operations are highly successful and give satisfactory profits. The output last year was 49,500 tons as compared with 44,950 a year ago. Of this 33,500 was exported averaging 16% copper, 26% lead, and 9 oz. silver per ton. At the smelter 16,000 tons of ore yielded 2940 tons of matte averaging 48% copper, 24% lead, and 14 oz. silver, together with 2732 tons of lead. The cost of mining increased from 11s. 6d. a year ago to 25s., a rise accounted for by the fact that the ore comes now from the second and third levels instead of from the open-cut. Rock-drills are employed, and a system of filling exhausted stopes with limestone has been introduced. The expenses of mining during the year were £60,600, and of smelting £68,600; the cost of bringing supplies and of shipping the ore and products was £136,400, and £35,000 was allowed for depreciation. The income from sales was £411,400, and the profit was $100,360. The company also operates the railway to the west coast at Swakopmond, and made a profit of £84,300 from this source. After paying administration charges and interest on debentures, the net profit of the company for the year was £168,000. The ordinary shareholders receive £100,000, being at the rate of 10%, and the deferred shares, of which there are 200,000 of no face value, receive £40,000, being 5s. per share. The company is taking an active part in the direction of the exploration work conducted by the Otavi Exploration Syndicate, a London company financed by English and German firms.

The report of the Mount Morgan Gold Mining Co., of Queensland, for the year ended May 31, shows that the total production of gold during the year was 187,867 oz., and of copper 7062 tons, obtained from 397,228 tons of ore. By chlorinating 124,122 tons of siliceous sulphide ore, 57,217 oz. gold and 499 tons of copper were produced; the blast-furnaces produced 109,363 oz. gold and 6563 tons copper; and 52,917 tons of oxidized ore yielded 12,287 oz. gold. Owing to depletion of the oxidized ore the extraction plant has been finally closed. The yield per ton from the smelting ore was 9.93 dwt. gold and 2.98% copper, as compared with 7.77 dwt. and 2.85% the year before, and the yield from the chlorination plant was 9.19 dwt. gold and 0.4% copper, figures practically the same as before. The report does not give the figure for the amount of copper sold but the price realized was £60 per ton. The total revenue was £1,079,914 and the expenditure £712,722; in addition £24,706 has been allowed for depreciation of plant, £50,000 has been added to the reserve fund, and £60,000 more has been carried forward than was brought in from last year. The dividends absorbed £150,000. The coal strike in Australia did not inconvenience the mine and smelter, as large stocks of fuel were in hand, but the works of the Electrolytic Refining Co., at Port Kembla, where the Mount Morgan copper is now refined had to suspend operations for a time. The Boyne Valley railway from the mine to Many Peaks was completed last month, and the regular supplies of basic ore will in the near future replace the barren ironstone flux hitherto brought from Iron Island. The plant has been enlarged by the addition of larger converters, so as to deal with the larger amount of matte that will be produced. The new system of filling old stopes has proved satisfactory, and no repetition of the cave of two years ago is expected. Much attention is being given to the question of improving the ventilation of the mine. Analyses of the air have not shown any absolutely dangerous proportion of undesirable gases or dust, but in the aggregate the samples showed that the average air is not up to a sufficiently high standard. To improve matters, a new upcast shaft is being sunk at the northwest end of the workings and will connect with all the levels.

The Robinson Deep, in the central part of the Witwatersrand is a 'second deep' being on the dip of the Robinson Central Deep and Ferreira Deep. It is controlled by the Consolidated Gold Fields and is isolated from others of the same group being surrounded by Wernher-Beit-Eckstein mines. Operations were started in 1898 with 40 stamps and the equipment now consists of 300 stamps and 5 tube-mills. During the year ended March 31, 738,495 tons was raised, and after the removal of 16% waste, 620,350 tons was sent to the stamps. The yield of gold was as follows: from the stamps 119,383 oz., from the tube-mill plates 30,223 oz., by cyanidation of sand 46,053 oz., and slime 13,113 oz., total 208,772 oz., an extraction of 6.73 dwt. per ton. The estimated content of the ore and the assay of the tailing are not given. The revenue from the sale of

Head-Frame at Mount Morgan Mine.

gold was £877,056 or 28s. 3d. per ton milled. The working expenses were £542,313 or 17s. 6d. per ton milled, leaving a profit of £334,743 or 10s. 9d. per ton milled. The dividends distributed absorbed £343,000 being at the rate of 35% on the issued capital. The output and profit were smaller than in the preceding year when the figures were: output £1,092,224, profit £525,222, dividend 42½%. The profit per ton last year, 10s. 9d. compares with 17s. 7d. a year ago, and the extraction per ton 6.73 dwt. or 28s. 3d. compares with 8.3 dwt. or 33s. 8d. A year ago is was announced that to keep the mill going the average ore would have to be of lower grade, so that the fall in yields and profits was anticipated. The reserve of ore on March 31 was estimated at 1,050,000 tons, having an average assay of 7.23 dwt. C. D. Leslie, the superintending engineer, reports that this reserve does not include anything in the Main Reef; it is hoped that the ore can be mined at a profit, but figures will not be given until actual results are obtained. During the past year stope-drills were introduced and at the date of the report 20% of the ore was mined by them. The miners have not as yet become accustomed to this type of work but the advantage of being able to reduce the stoping width by their use is already apparent. The mine has suffered a good deal lately from

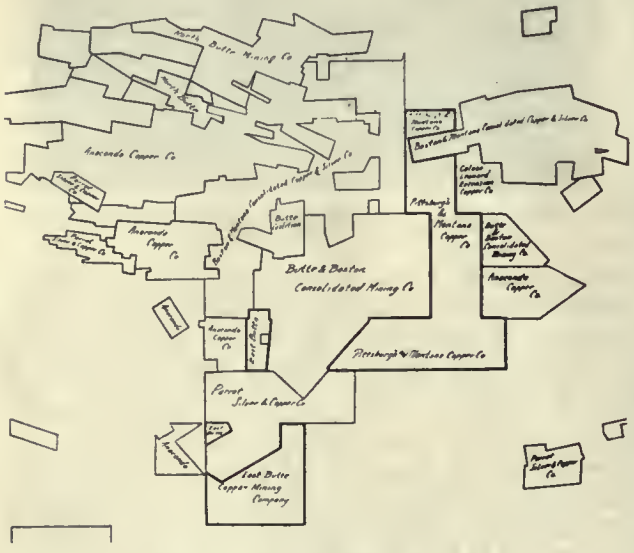
scarcity of labor, and during the latter part of the year, the mill was not running full time.

The days of the Treasury gold mine in the Central Rand are numbered. This is a small outcrop mine situated between Geldenhuis and Jumpers, and during recent years it has been under Neumann control. Dividends were first paid in 1892. In 1894 and 1895 additional property was acquired and the new plant, consisting of 40 stamps, was erected. At the same time the nominal capital was inflated to £540,000. The report for the year ended March 31 last, shows that during that period 148,154 tons was mined and after removing 26% of waste 109,235 tons was sent to the mill, which now consists of 60 stamps. The average assay of the ore was 6.4 dwt., and just 50% of this was recovered in the mill, the figures being 17,569 oz., or 3.21 dwt. per ton. The cyanide plant treated 82,043 tons of sand assaying 3.47 dwt., with an extraction of 2.83 dwt., and 26,871 tons of slime assaying 1.95 dwt., from which 1.67 dwt. was obtained. The total extraction was 5.76 dwt. or 90% of the content. In addition 7341 tons of accumulated slime was treated, averaging 3.54 dwt. and yielding 2.75 dwt. The total recovery of gold was 32,468 oz., worth £135,972, and the expenses were £111,096, leaving £24,896 as balance of profit. Out of this profit £6185 has been used for the extinction of the debenture debt and for the payment of interest during the year, and £1382 was spent in clearing a fall of ground and retimbering. The balance was carried forward. No dividend has been distributed for the last five years. The engineers estimated that on March 31, the reserve blocked out consisted of 201,580 tons averaging 5.68 dwt.; in addition the undeveloped ground is expected to contain 108,459 tons of profitable ore. The life of the mine may therefore be expected to be two years from the present date.

BUTTE, MONTANA

August Production.—Butte-Ballaklava.—Butte & Superior.

A good deal has been said and written during the past two months about the curtailment of the copper output. John D. Ryan, of the Amalgamated Copper Co., now in this city, does not deny that there is a curtailment in the production in this district, but he says that it is not of



Map of Claims at Butte, Montana.

sufficient size to create any alarm, and further he hopes that the curtailment at present in force will not last long. This curtailment has been brought about gradually and a glance over the figures shows that there has not been any decrease during the month just closed as compared with July. However, the mines of the district are hoisting and sending to the smelters a lower grade of ore, which will require more to produce the same amount of copper than has been shipped in months past. This means that the smelters at Great Falls and Anaconda will continue to receive almost their capacity of ore and that the mines will hoist even more, so that no more men will be laid off. The mines of the Anaconda company continue to work seven days and the mines of the Boston & Montana company six days per week. In reference to the curtailment matter it may be stated that the output of all the mines in the district in May was 27,103,000 lb. of copper, and that the August output was about 24,000,000, which means there is a decrease scattered among all the properties of 3,000,000 lb., of which the independent producers, the Butte-Ballaklava, the Tuolumne, East Butte, and miscellaneous small mines, contribute nearly 1,000,000 lb. The Boston & Montana group of mines contributed another million pounds, and the remainder is divided among the Anaconda group, which now includes the Clark properties. The August production of copper by the Butte companies is estimated at 24,762,800 lb., compared with 24,261,000 in July, and 26,317,200 in June, showing that there has been no further reduction in the output. The daily ore tonnage, average yield per ton, and gross daily yield of copper for August were as follows:

Companies.	Tons per day.	Yield per ton (lb.).	Yield per day (lb.).
Boston & Montana	3,000	70	210,000
Anaconda	4,270	62	264,740
Butte & Boston	500	63	31,500
Washoe	390	61	23,790
Parrot	130	64	8,320
Trenton	425	62	26,350
North Butte	1,000	64	64,000
Butte Coalition	1,420	70	99,400
Original	450	65	29,250
Tuolumne	100	85	8,500
Butte-Ballaklava	135	160	21,600
East Butte	120	80	9,600
Miscellaneous	25	70	1,750
Totals	11,965		798,800

The month's total tonnage of ore and total copper production were as follows:

Companies.	Tons of ore	Pounds of copper.
Boston & Montana	93,000	6,510,000
Anaconda	132,370	8,206,940
Butte & Boston	15,500	976,500
Washoe	12,090	737,490
Parrot	4,030	257,920
Trenton	13,175	816,850
North Butte	31,000	1,984,000
Butte Coalition	44,020	3,081,400
Original	13,950	906,750
Tuolumne	3,100	263,500
Butte-Ballaklava	4,185	669,600
East Butte	3,720	297,600
Miscellaneous	775	54,250
Totals	370,915	24,762,800

Work has been temporarily stopped on the ground in dispute between the Anaconda company and the Butte-Ballaklava company, pending the action of the court in the matter of the restraining order. In this connection John A. Percival, secretary of the Butte-Ballaklava company, has issued a statement in which he declares that there is no question as to the rights of his company. He says that for over one year the company employed its entire mining force on the work of proving beyond all doubt whether or not the veins opened apex on the Butte-Ballaklava property. He says the surface was trenched from one end to the other, laying bare the veins traversing it for a total length of 3600 ft. From the lower levels raises were made on these veins, showing direction and dip in such a conclusive manner as to establish beyond all doubt that the apexes of all the orebodies opened by the company were on the property. Work is still going on in the Ophir mine of the Butte Central Copper Co., but no effort has yet been made in the way of attempting to commence the sinking of the shaft from the 500-ft. level to a depth of 1500 ft. as proposed.

TORONTO, CANADA

Increased Market Activity.—Bullion Shipments.—Porcupine. — Northern Ontario Development.

There are some indications of a revival of public interest in Cobalt mining enterprises, and during the last week or so there has been a slight upward movement in stocks, and an increase in the number of transactions sufficient to warrant the expectation of an active fall campaign. Shipments of ore are well maintained but otherwise there is very little news of interest from the camp. A noteworthy happening, however, is the rehabilitation of the Cobalt Townsite, the case of which had been for some time regarded as hopeless, which is now taking out ore and shipping steadily, having sent away 118 tons extracted from the shaft near the Buffalo. Some good ore has been also blocked out at the old shaft near the track, where work will be resumed later. A large consignment of bullion amounting to 6897 lb. was recently shipped to London from four mines, the O'Brien, Temiskaming, Nova Scotia, and Silver Cliff. The O'Brien mine is now sending out most of its silver output in this form. With the exception of what was sent from the Buffalo there was hardly any bullion shipped from Cobalt previous to the present year. The quantity sent out by the Buffalo up to the end of 1909 amounted to 57,317 oz. and the O'Brien last year made a small shipment of 814 oz., whereas the shipments of bullion for 1910 amount to 353,963 oz. of the value of $195,638. The recent discovery at the 100-ft. level of the Hudson Bay is considered one of the most valuable finds of the present season, assays of the vein running over 6000 oz. per ton in some places. At the La Rose the value of the new vein at the 135-ft. level on the Princess property is confirmed, as assays of 4900 oz. extending over 2 in. of the vein have been obtained. The west stringer of the main La Rose vein, developed by a drift 20 ft. above the second level, has widened to 5 in., the ore containing between 2000 and 3000 oz. silver per ton. J. W. Astley, consulting engineer of the Peterson Lake, has resigned, his place being taken by S. M. Thorne, formerly of the Silver Leaf.

Favorable reports as to the progress of the Porcupine camp continue to be received, notwithstanding the drawback of transportation difficulties and scarcity of provisions, the principal development being in connection with the large group of claims held by what is variously known as the Timmins, McMartin, or Dunlop syndicate. It is composed of Noah and L. H. Timmins, John and Duncan McMartin, and D. A. Dunlop, and owns in all 70 claims on which three shafts are down, that on the Hollinger having reached a depth of 140 ft., and one on the Miller-Middleton property 100 ft. It is reported that $1200 per day in gold is being taken out, and that 10,000 tons of ore have been blocked out. The Dome has a Nissen 1200-lb. stamp-mill crushing 5 tons of ore per 24-hr. day. The Porcupine Gold Mines Co. has 10 tons of ore which it is estimated will run about $1000 per ton. A stamp-mill will shortly be installed. The Scottish Ontario has a shaft sunk nearly to the 100-ft. level. When this is reached a cross-cut will be run across the entire lot.

There is some revival of interest in the gold mines of northwestern Ontario. The Lawrentian mine in the Manitou Lake area has been acquired by the Merger Mining Co. and will henceforth be known as the Merger. Development will be undertaken with E. R. Warner in charge. The Redeemer in the Eagle Lake district, will also be re-opened under the management of Frank E. Roberts, formerly of Arizona. The Ophir mine in the Kenora district, which has been closed for some years owing to litigation, will again be worked. A contract has been let for the sinking of a shaft on the vein. Mackenzie & Mann, of Toronto, the Canadian Northern Railway magnates, have taken up options on iron-ore claims covering 4410 acres at Grand Rapids on the Mattagami river on the Hudson Bay slope of northern Ontario, having outbid the United States Steel Corporation, which was anxious to obtain the property. They will put five diamond-drills to work immediately and it is stated that should the property prove up, the price to be paid reaches a high figure. The purchase covers practically all the exposures of iron ore on the Grand Rapids field.

SALT LAKE, UTAH

Copperton Mill Dismantled. — Electrostatic Zinc Plant. — Park City Mines.—Eureka Properties.

The Copperton mill of the Utah Copper Co., which was closed down a few weeks ago, will be dismantled and the equipment used in the remodeling of the old Boston Consolidated mill along Utah Copper lines. This will provide equipment for about one-fourth of the Boston Consolidated plant which will be shut down and remodeled in sections. Boston Consolidated has been entirely liquidated, the last formalities having been gone through with. Production of the Utah Copper for the month of July was 8,677,851 lb. of copper. Some details of the reported financing of the Ohio Copper Co. have been made public since the return of F. Augustus Heinze from his trip. He states that certain French bankers have agreed to sell $1,000,000 worth of Ohio bonds within three months from October 10. This means that the money will not be available to the company until January 10 and, as the issue is not underwritten, they do not make any guarantee to deliver it at that time. This announcement, coming after definite statements that the company had been financed, is a disappointment to stockholders, but Mr. Heinze is confident that the bonds will be sold and the money paid over

Yampa Smelter, Bingham Canyon.

at the time stipulated. The mill is in such shape that the installation of the remainder of the equipment will not take long.

At the International smelter matte has been tapped and two converters are in operation. The Utah Consolidated tramway is delivering about 700 tons of ore per day and is being put in shape to handle the full amount called for. Announcement has been made that four of the reverberatories will be put in shape as soon as possible, this being one more than originally expected. F. W. Cowans, formerly of Mexico and Peru, has been appointed superintendent for the Utah Consolidated, and will have active charge of the operation of the property under the direction of Roscoe H. Channing, consulting engineer. These changes have been brought about by the resignation of J. B. Risque, general manager for the company. Mr. Channing was manager previous to Mr. Risque.

The United States Smelting Co. is making some experiments with its electrostatic zinc plant, at Midvale, with the object in view of materially increasing the capacity. If this cannot be accomplished with the present plant an addition will be built. The working force at the mine has been materially increased. The Yosemite, which was recently unwatered and which has opened good ore on the lowest levels, is to resume active operations at once. New equipment is to be installed at the shaft which will be cleaned out and put in shape. The mine which operated as a lead producer above the water-level will now be worked for its copper content. A large portion of the stock is con-

trolled by the Bingham Mines Co. This company has taken over the Sampson recently. Since the closing of the Yampa smelter it is shipping to the American Smelting & Refining Co. At the Daly-Judge the company is experiencing no trouble in holding the 1600-ft level which was recently unwatered for the first time in twelve years. A few of the old drifts have been found caved but some ore has already been opened and it is on this level that the mine penetrates the Ontario quartzite which has produced most of the wealth of this zone. The Daly West has struck some good ore on the 1900-ft. level while extending the drift from the Ontario drain tunnel to the Daly-Judge. Work has been started extending the 2100 or main tunnel-level to the point where the ore thus found should appear below. Some Colorado capitalists are negotiating for a long-term lease on the American Flag with the privilege of buying a large block of the company's treasury stock. The Gold Chain and Opohongo have entered into an agreement which should result to their mutual benefit in installing a joint hoisting and power equipment. A new 16-drill compressor has been ordered and plans are being made for new hoisting works for the two companies.

The new pumping equipment of the Centennial Eureka met with a peculiar accident in that the water column expanded due to the water being slightly warmer than the air in the shaft, the column being rigidly fastened at the top, buckled so that it was necessary to shut the pumps down while repairs were made. These are practically completed so that the plant will be in operation in a very few days. A case of long standing in the courts was decided in the Supreme Court and by it those Success stockholders who have been suing for a block of Colorado stock have lost on all counts. The proposed merger of the South Columbus Consolidated and the Alta Hecla is being met with considerable opposition and both sides are out with statements of their case. Those in favor of it claim that it will lift the stock out of the cheap class and place the company in a position to go ahead and develop its property and prove it up while the opponents claim that the South Columbus is worth far more than will be paid for it by the terms of the proposed merger and that the benefit will accrue almost entirely to the Alta Hecla. The meeting of the stockholders to ratify or reject will be held this coming week and there should be some interesting developments.

JOHANNESBURG, TRANSVAAL

The 'New Metallurgy' on the East Rand. — June Output. — An Unfortunate Venture.—The Farvic Mine, Rhodesia.

For the past four or five years the average Witswatersrand stamp-duty has been steadily increasing on account of the employment of much heavier heads, coarse screening, and tube-mills. Not a few mines have been maintaining eight tons per day duties for several months, but all records in this respect have now sunk into insignificance in the light of recent milling operations at the East Rand Proprietary mines. E. H. Johnson, consulting metallurgist to this company, has for some considerable time past been experimenting at the Angelo & Cason mills in the direction of higher duty, and as a result of his investigations 80 stamps supplemented by 8 tube-mills are now running there (40 in the Cason and 40 in the Angelo batteries) at a duty of about 25 tons per day. Mr. Johnson anticipates that in a few days' time the duty will be 30 tons. The East Rand Proprietary is now operating 820 stamps and 24 tube-mills. The distribution of the stamps is as follows:

	Stamps.
Driefontein mill	220
Angelo mill	220
New Comet mill	160
Cason mill	220
	820

The Driefontein and New Comet batteries are steam-driven and are more costly to operate than the more modern electrically-driven mills of the Angelo and Cason. The proposal now receiving the consideration of the company is the cessation of work at the two older steam-operated mills and the concentration of reduction operations at the Angelo and Cason plants. The experimental work carried out on a large scale in these two latter mills has shown that the company will, with these 440 stamps at work, supplemented by a large number of tube-mills, be able to crush more ore than the full 820-stamp equipment milled under the old working conditions. This will naturally result in substantially decreased working expenditure and it is important to learn that at the 80 stamps, where the high duty already referred to has been obtained, the pulp leaving the mortar boxes has been even finer than the product leaving the batteries where such an ambitious crushing scheme has not been carried into effect.

This is one important result which will be secured to the company through the full adoption of the project for the consolidation of the four properties achieved a year or two ago, as there will now be no necessity or question of having to operate this or that mill or haul ore through this or that shaft because they belong to any particular company. The Angelo and Cason batteries are well situated as regards the shafts and crusher stations of the four mines, and the new scheme which has only been rendered practicable through amalgamation will, when carried completely into operation, have a most marked and satisfactory effect on the profit earnings of the company.

The statistics prepared by the Transvaal Government Department of Mines for the month of June show that 103 gold mines were dropping stamps during the period. The total stamping capacity employed was 9853 heads and in addition 182 tube-mills were at work. The following tables state the distance of these mines from Johannesburg, the number of stamps and tube-mills operated in different areas, and the quantities of ore milled:

	No. of miles.	Stamps at work.	Tube-mills at work.	Tons milled.
Witwatersrand area	62	9,240	173	1,775,586
Heidelberg	3	125	2	19,637
Klerksdorp	4	40	3	4,000
Pretoria	1	5	..	410
Barberton	15	230	1	16,393
Pilgrim's Rest	15	183	2	18,420
Pietersburg	3	30	1	2,264

Of the total tonnage milled in the Transvaal only 2300 tons out of a total of 1,837,000 were reduced in the first place by other means than gravitation stamps, a fact which indicates the general similarity of practice in Transvaal ore reduction, although of course there are large variations in detail at the different mines. The yields of the mines during June were:

Witwatersrand	£2,517,206
Heidelberg	30,558
Klerksdorp	4,687
Pretoria	241
Barberton	21,343
Pilgrim's Rest	49,652
Pietersburg	2,853

It is officially announced that the Vogelstruis Consolidated Deep mine near Florida is being closed down. The company commenced milling at the beginning of the year and has declared a substantial loss each month. Three or four weeks ago a circular was addressed to shareholders inviting them to subscribe £210,000 for a debenture issue, the proceeds to be devoted to further developing the mine and increasing the milling plant from ten to fifteen thousand tons per month capacity. This invitation has met with an exceedingly poor response; scarcely to be wondered at considering that the company is already heavily in debt, and that if it is to be turned to profitable account the proposition will have to be developed and equipped on a substantially larger scale than was mentioned in the circular. It is not often that a Main Reef venture has to be admitted unprofitable, but it is clear that the Vogel

Deep has, to date, been an utter failure as a separate mine, and shareholders in the company must now seek what comfort they can from the nebulous prospect of the company's claims being at some day included in an amalgamation scheme.

Yet another Rhodesian mine which hitherto has been worked as a tributing venture is to be floated with a substantial working capital and a large authorized capital. During the past year or two several properties in the Matabeleland and Mashonaland provinces of southern Rhodesia have been acquired from small mine workers and tributing syndicates by influential South African mining houses and have been floated under important auspices. For instance the Buck's Reef Gold Mines acquired from Mr. Wood the Buck's Reef mine. The company has a capital of £150,000, the sponsors in the formation of the company being H. J. King and S. Neumann & Co. Then, too, the Lonely Reef was purchased by Lewis & Marks from Palca & Aserman, the fortunate owners receiving £125,000 in cash and 75,000 shares in the Lonely Reef G. M. Co., which has an issued capital of £271,000. The Masterpiece mine in the Hartley area has been sold for £100,000 in cash, and the latest addition to the list of mines previously worked on a very small scale, and now being taken over by large companies is the Farvic. This property is situated in the Gwanda district of Matabeleland and has been worked on tribute for some months past by Rhodesia, Ltd. The adjacent Colleen Bawn mine is equipped with a 6-stamp battery, cyanide, and slime plant and these have been employed by the Farvic. Some idea of the high-grade nature of the ore found may be gained from the fact that for the six months ended March 31, 4461 tons were milled for a total yield of £45,036. In May the value of the output was £6198 and a profit of £3842 was earned. The owner of the Farvic claims, H. S. Henderson, and Mr. Stewart, manager of Rhodesia, Ltd., are now in England arranging for flotation of a company to take over the mine and work it on a scale commensurate with its possibilities.

NEW YORK

Market Stagnation.—Bond Issues.—Ebner Gold Mine. — Copper Companies.—August Exports—Canadian Production.

A committee of citizens from Jim Fiske's native town once solicited him to contribute toward a fence to be built around the local cemetery. Fiske's reply was that "the burying ground did not need any fence. Those that were in could not get out and those that were out did not want to get in." Words could hardly express more aptly the condition of the securities markets at present. Not only do those who are out not want to get in, but they refuse to come in upon invitation, entreaty, command, or compulsion. The volume of business upon the New York Stock Exchange has dwindled to small proportions. The course of prices has been such as to demonstrate clearly the fact that the larger interests, the bankers for the leading railroad and industrial corporations, are in complete control of the market. Complete control of everything except the absorbent element which they find themselves powerless to build up. Mr. Roosevelt's series of speeches made on his Western trip, has not helped to quiet the financial unrest prevailing. Just how far the political situation is to affect the securities market is yet to be seen. The present stagnation is almost as complete as possible. Some revival, at least, of activity must be expected. The situation in the coppers has developed into a waiting game. The copper curtailment is evidently to eliminate accumulated stocks as a market menace; on the other hand, a marked decrease in consumption is inevitable under prevailing business conditions. The cutting down of production has undoubtedly averted a violent upset in the metal market and a further drastic shrinkage in the copper share list. Under present circumstances the metal market must wait upon general business conditions before the hoped for revival can take place. In the meantime the gathering of the copper industry into compact form in a few hands goes on rapidly. Consolidations are in progress wherever feasible. The announcement made last week that the Nevada Consolidated-Cumberland Ely merger had been consummated was a little premature. A group of stockholders, representing in all some 2200 shares of stock, organized at the last moment under the leadership of a New York Stock Exchange house, and secured a temporary injunction preventing the contemplated transfer of the Cumberland Ely property. The Nevada Consolidated management has unofficially made an announcement that, if the rebellious stockholders insist upon holding their position, it will only result in the continuation of the present status and the maintaining of a separate corporate existence for Cumberland Ely, for the benefit of 1½% stock interest, 98½% of the outstanding stock of Cumberland Ely being in the Nevada Consolidated treasury. Both of these concerns, together with Utah Copper, have just declared regular quarterly dividends; Cumberland Ely, 10c. per share, practically all of which goes to Nevada Consolidated; the latter is paying 37½c. per share, of which almost exactly half goes to the Utah Copper Co., which is in turn disbursing 75c. per share. When Utah Copper shall have absorbed Nevada Consolidated, Ray Consolidated, and Chino, as it will in due course without doubt, it will be in position to take the leadership in copper from Anaconda. In fact, Utah Copper is already encroaching upon Amalgamated marketwise. There are many holders

Copper Flat, Ely, Nevada.

of Amalgamated who bought well above par and who are far from satisfied with the return of $2 per year derived from Amalgamated, quoted in the present market about 64, especially when compared with Utah, quoted at 46 and returning $3 per year. On this basis two shares of Amalgamated will practically buy three shares of Utah, upon which the return is $9 per annum, as against $4 on the two shares of Amalgamated. Commission houses are said to be executing many such 'switches.' In view of prevailing conditions, the growing importance of the porphyries and the dominant place they are to occupy, at least during the next few years, it is hard to find any argument effective against the potent one of greater income. A copper cost of 5¾c. per pound for its last quarter and on a production of over 18,000,000 lb. marks Nevada Consolidated as the lowest-cost large producer of this country, if not of the world. Utah Copper's production at a rate of more than a hundred million pounds per annum, is showing a net of something more than 10% upon its $15,400,000 outstanding stock, and these results have been reached in the face of the most discouraging metal market seen for some years. The other Guggenheim dividend payers are declaring the usual quarterly disbursement; Yukon Gold, 10c. per share, which is at the rate of 8% per annum; and Guggenheim Exploration, 2½ per cent.

The calling in of all of the outstanding bonds of the Butte & Boston Consolidated Mining Co., a little more than $500,000, for redemption is claimed to wipe out all of the bonded indebtedness against the group of properties controlled by the enlarged Anaconda. The incident has also directed some attention to the large part played by convertible bond issues in recent mine financing. The Nevada Consolidated bond issue has all been redeemed, but before they were converted they sold at $400. The bond

issues put out by the Utah Copper and by the Boston Consolidated also sold at much above par. The conversion privilege gives to the bond all the speculative value that lies in the stock, while the lien upon the assets ordinarily ensures such minimum of risk as satisfies more conservative investors. Some new issues have appeared recently; the principal ones being Ohio Copper, $1,250,000, a million of which F. A. Heinze says he placed with French bankers while abroad; Miami Copper, $1,500,000; South Utah, $3,000,000; Utah Copper, $2,500,000 for the financing of the Bingham & Garfield railroad; Mason Valley, $1,000,000, the proceeds to be used in the erection of a smelter at Yerington; and Braden Copper, $4,000,000, to be sold to equip the property in Chile and provide transportation facilities. A survey of the financing required in the development of the modern porphyry copper property shows as distinctly as any phase of the mining industry, the great growth of the coppers. That the financing is needed to be on a large scale is shown by the recent placing of one order for 1500 Isbell vanners to go into the mills of Ray Consolidated and Chino. This is claimed to be one of the largest orders for mining machinery ever placed in this country.

It is not, however, the coppers alone that are requiring equipment. The California Nevada Copper Co., which controls the Ebner Gold mine near Juneau, is building a 200-stamp mill, which is to be simply the first unit of a plant which is to have 1000 stamps of 1500 lb. each before it is completed. This first unit of the mill is expected to be in operation before the first of the year. This property is held to be another Alaska Treadwell, with immense orebodies of free-milling ore averaging about $3.50 per ton. The property is opened by two adits; the millsite is at the portal of the lower one, so that ore will come to the bins by gravity. Mining and milling costs are expected to be between 60 and 75c. per ton.

The special meeting of the stockholders of the Miami Copper Co. was held this week to ratify the proposed increase in the capital stock of the company. J. Parke Channing, head of the engineering staff of the General Development Co., stated at the meeting that the present developed ore of the Miami totals between fourteen and sixteen and a half million tons, that the copper content will be well toward 3%. The Miami mill is to be in operation in January, the present mill is to handle 2000 tons per day, but foundations have been built for an addition to be erected as soon as possible after the present mill is operating. The situation in Giroux is not wholly satisfactory. The company has adopted a policy of withholding all information both from shareholders and from the public. It was anticipated that shipments from the Giroux would probably begin when the smelter at Tooele was blown in. The first pouring of copper at the new smelter was made this week, but the date of initial shipments from the Giroux is still a matter of conjecture. There has been much selling of Giroux in the open market, some of which, conducted through one of the largest New York Stock Exchange houses, is said to have been for treasury account. Friends of the property argue that Thomas F. Cole, the managing head of the company, would not endorse the expenditure of $125,000 upon the five-compartment Alpha shaft if there was not demonstrated tonnage to justify it. Nevertheless, Giroux could make a lot of friends in the market now by putting forth a frank and complete statement covering finances and physical conditions, particularly the latter. The merger of the Superior & Pittsburg and the Calumet & Arizona is still under consideration, but is halted by a somewhat unusual obstacle. Superior & Pittsburg is organized under the laws of the State of Minnesota, which in such case require the unanimous vote of the stockholders. It is conceded that it would be almost or quite impossible to secure proxies representing every share of stock.

August exports of copper have been large, amounting to 62,666,240 lb., according to custom-house returns. Notwithstanding the heavy exports ruling throughout the earlier part of the year, the European visible supply has steadily decreased since February 15 up to August 15, thus showing an enormous consumption abroad. Germany, in particular, is just now crowding her factories to the utmost and is using unprecedented quantities of copper. The increase in the visible supply during the latter half of August amounting to some 2,000,000 lb., was fully discounted as the result of the known heavy exports. Domestic deliveries for August are estimated at 60,000,000 lb., and while production is hard to estimate, it is believed that the coming report of the Copper Producers' Association will make a very encouraging showing as compared with the earlier months of the year.

The Dominion Department of Mines has just issued a report covering the mineral production of Canada during 1909. The total exceeds $90,000,000, as compared with about $86,000,000 in 1908. In the production of gold there has been a large shrinkage. In 1900 the gold production of Canada was $27,908,153; in 1907 it was $8,382,780; in 1909 $9,790,000. As the gold production has decreased the silver output has swollen. In 1900 the latter totaled $2,740,362; in 1907, $8,348,659; in 1909, $14,358,310.

The Batopilas Mining Co. shows, by its annual report, a net profit for the year 1909 of $52,782.12 and a total surplus of $3,268,534.61. The Batopilas numbers among its board of trustees some of the most influential men in New York, among them being Morgan J. O'Brien, who was a co-trustee of the Equitable Life Assurance Society with the late Grover Cleveland; and Judge Henry E. Howland, one of the best known members of the New York Bar. Goldfield Consolidated, listed upon the New York Stock Exchange some weeks ago, has now complied with all the requirements of the listing committee and is now traded in on the floor. The shares passed by the committee aggregate $35,591,480. The mining market in London is said to be fast recovering its strength, now that the rubber and oil booms have run their course, and not a few promotions are being shaped up to be taken to England. An increasing English interest in Mexico is apparent, and the recent examinations made for the Rothschilds in Cananea are believed to be the forerunners of some heavy purchases of mining ground in northern Sonora by these financiers. The El Rayo Mines Co. reports a net profit, for the quarter ended July 31, of $88,524, won from 13,900 tons of ore of an average value of $14.48 per ton. El Rayo is in process of absorption by the Mines Company of America, which is also to absorb the Dolores Mines Co. After this merger is completed, Mines Company of America is to be listed upon the New York Stock Exchange. Boston capitalists have become interested in the Arizona Mines Co., which is developing 144 acres of ground in the Castle Creek mining district, Yavapai county, Arizona. Five thousand shares of stock have been sold to provide working funds, and the stock sold has been listed on the Boston Stock Exchange.

RADERSBURG, MONTANA

Keating Gold Mining Co. — Black Friday. — Radersburg-Rena.

The Keating Gold Mining Co., operating in Radersburg district, is shipping five cars of ore per week to the Pittsmont smelter at Butte. The wagon haulage of eleven miles to Toston costs $2 per ton, and freight charges from Toston to Butte are $1.25. Most of the ore being shipped consists of gold-bearing iron sulphide, containing some silver and copper; the average value being somewhere between $12 and $18 per ton. It is understood that the iron content is paid for as FeO at the rate of 10c. per unit, instead of as Fe at some other plants. These ores are free from zinc. The principal workings are on the Blacker-Keating vein, described in the *Mining and Scientific Press* of August 6. The old Keating vertical shaft and the new incline shaft are 800 ft. apart. The former, 400 ft. deep, is equipped with a Sullivan air-compressor, and a hoist operated by compressed air; also, an air-driven pump at the 400-ft. station, which is lifting 75 gal. of water per minute. At the incline shaft is the electric sub-station connected by an 18-mile transmission line to the plant of the United Missouri River Power Co., situated at Boulder, supplying power for a 12-drill air-compressor, Ingersoll-Rand, and a Nordberg electric hoist by which a 1½-ton skip is operated

between the surface and the 675-ft. station of the incline. The first 475 ft. of this incline was sunk on the vein, which has a dip west of 50 to 60°; the lower 200 ft. was sunk in the foot-wall, making a cross-cut of 15 to 20 ft. necessary to open the vein from the fifth and sixth stations. This arrangement affords better room for an ore-loading pocket at each of those stations. The 400-ft. level of the old shaft corresponds to 475 on the incline. This level is 1500 ft. long, extending from the old shaft northward on the vein to the new incline and 700 ft. beyond it. There is still a considerable amount of stoping ground above this level. The newer development is on the fifth level, which is at the depth of 575 ft. on the incline. Driving on the vein is in progress with air-drills in both directions, resulting in establishing a level several hundred feet long. Raises are being made in ore for the purpose of starting the work of stoping. The base of the incline has just reached the depth of 675 ft., where a cross-cut is being driven to the vein, the purpose being to start driving at this station and open level No. 6. The body of ore between the fourth and fifth levels gives promise of yielding a good tonnage. When the fifth level is extended south to a place immediately below the old Keating shaft a raise will be made to connect with the latter to establish good ventilation. The vein is between hard, well-defined walls, and the vein-filling, as a general practice, is all mined and shipped. While the average width is probably close to two feet, there are places where the vein widens to five feet, and others where it pinches to less than six inches. It is stated that the old workings, those at and above the 200-ft. level, contain considerable oxidized ore of milling grade. The mine superintendent is R. Hightower.

The Black Friday mine, situated about two miles from the Keating, was taken possession of on February 1, 1909, by the Toston Leasing & Mining Co., under a bond and lease. The lessees shipped 1002 tons of ore between June 1909 and March 1910, the net returns for which amounted to $43,372, or $43.28 per ton. Parties in control of the lease organized last March the Black Friday Gold Mining Co., which took over the lease and assumed the obligations thereunder. Since doing so considerable ore has been shipped which yielded an average of $45 per ton. The sampling showed the lowest to have assayed $28.75 and the highest $100.66 per ton. At present shipments amount to 20 tons per day. The shaft is an incline which has reached a depth of 500 ft. on the foot-wall. There is said to be 200 ft. of stoping ground above the 400-ft. level. Driving on the 500-ft. level is in progress, there being 3 ft. of ore in the face of the drift which assays $50 per ton. A raise in ore is being made from this level for the purpose of starting stopes. The ore in this raise is said to be 8 ft. wide. The plan is to sink below the 500-ft. station. The hoisting is done with steam-power, but the intention is to install an electric hoist within the next few months and obtain power from the United Missouri River Power Co., whose line passes close to the mine. It is stated that the final payment on the bond is to be made within the next 30 days, when the Black Friday Gold Mining Co. will have complete ownership of the mine. Willard Bennett, A. J. Galen of Helena, R. M. O'Hearn, and A. B. Bennett of Toston are the officers of the company, the last named being general manager. The ore characteristics of the Black Friday are similar to those of the Keating, though the grade of the former is the higher of the two. Ample power for mining and milling is available, as the United Missouri Power Co. has just completed a new generating station.

The Radersburg-Rena Gold Mining Co. is developing the Rena, half a mile north of the Keating, on which there is a 250-ft. incline shaft on the vein. Some driving has been done from the 250-ft. station in sulphide ore, shipments from which sampled 38 to 44% iron and $30 gold per ton. The property has a steam-hoist and the intention is to do more sinking. The matter of connecting with the electric power-line and using an electric hoist is being considered. F. H. Donaldson of Helena, C. E. Gruwell of Butte, and J. H. Tullock of Lombard are most concerned in the property, Mr. Donaldson being the manager.

FAIRBANKS, ALASKA

New Discoveries.—Increased Milling Facilities Needed. — Value of Shipments.

New quartz discoveries have been reported of late, and with the previous finds have stimulated prospecting, and the whole belt between Ester dome and Pedro dome is attracting renewed attention from 'sour-dough' prospectors and 'cheechakoes' alike. Though most of the good prospects lie within a few miles of Pedro dome near the Cleary summit, the formation around Ester is just as favorable. After the finds of Herschberger, Fredericks, and others on the ridge connecting Ester and Pedro, several miles from the older district, chances for further extensions of the gold belt are greatly enhanced. While the prospectors are hard at work, the mill at Fairbanks is grinding steadily on high-grade ore. Now that the stamps have been enlarged to 500 lb. the tonnage is greatly increased, though even at that, shipments are ahead of the capacity. During July several good clean-ups were made. A 5-ton lot from the Lawson, Zimmerman & McCarty veins at the head of Wolf creek assayed $90 per ton in free gold. About three tons of this lot was practically waste, showing that the value of the ore must have been more than double this figure. Lucien Rhodes also put through a 6-ton lot which resulted in a retort worth over $900, being of slightly better grade than usual. Other mill-runs from the same property have averaged $150 per ton. Charles Crawford, who operates a lease on part of the Rhodes-Hall vein, is now shipping steadily from his winter dump and from his present workings. Spaulding & Clough are working on their adit. This property is at the head of Dome creek on the right limit and rich ore has recently been extracted, the gold being coarser and brighter than that in the shaft at the upper end of the claim. They have found no indications so far to show that the pay does not extend the full length of the claim. George and Ed. Thomas have taken a lease on the Wild Rose claim, the extension of the Spaulding-Clough property. Ed. Thomas has till recently been placer mining on the lower end of Dome creek.

The arrastre at the head of Skoogy gulch built by S. Scrafford is running steadily. The last clean-up was reported as showing $50 per ton of ore crushed. As the ore is friable, about two tons is crushed per day. The Redwing Leasing Co., owned by Emil Furstenau and S. R. Calvin, is installing a hoist on their lease of the Jupiter-Mars property. Cross-cuts at the 60-ft. level have opened a good grade of ore. Work has commenced on the foundations for the Chena customs mill by Martin Harrais and associates. While only part of the machinery has arrived, the entire outfit should be on the ground soon. It is understood that the equipment will be complete in every respect. Lawson, Zimmerman & McCarty are figuring on installing air-hammer drills at their properties at the head of Wolf creek. The order will probably be telegraphed to San Francisco in a few days, so the last through boat to St. Michael can bring in the drills before the close of navigation. As the company intends to sink at least 150 ft. and cross-cut 100 ft. each way, the use of power-drills will greatly facilitate the work and save at the same time a large labor bill.

Advices from Fairbanks creek state that the Cook brothers have opened a much larger body of high-grade galena than was shown in the first prospect shaft. Samples from the first shaft showed a large percentage of lead and 220 oz. of silver. Horton and associates have just brought in samples of ore from their vein showing a high value in free gold. The gold is coarse and bright. Some of the specimens are as rich as any yet found in the district and look to be worth about $30 per pound. In this vein antimony is the base metal, and where it shows the strongest, the value changes to silver. Representatives of the Copper River & Northwestern railroad are in Fairbanks at present looking up possible tonnage in case the road is extended to Fairbanks. They are at present engaged in visiting the mines, although they will also note the agricultural possibilities of the district. A large amount of farming land would be made available by such a road.

General Mining News

ARIZONA

COCHISE COUNTY

The fifth level has been started in the Centurion mine at Dragoon, and the management plans to commence shipping ore to the smelter within the next two months. It is probable that the first ore shipped will be sent to the Copper Queen smelter at Douglas.——Thomas Higgins has completed a survey for a patent of 40 claims some of which adjoin the Centurion property.——Operations are to be resumed at the Jim Neal group within the month.——New machinery is to be installed and work resumed at the Pawnee group in the Paradise district. Assays of the ore running $38 gold with 12% copper have been obtained recently from the shaft which has been sunk 100 ft. on the vein. There is also a 180-ft. drift on the claims.——The assessment work is all that is being kept up at the Bradshaw & Arizona at present, but it is planned to do some extensive diamond-drilling the first of the year.——The officials of the White-

Map of Arizona.

tail company are considering the erection of a mill to treat custom ore as well as that produced from their own property.

GILA COUNTY

(Special Correspondence).—The diamond-drill on the 660-ft. level of the Superior & Globe mine is running at a depth of 230 ft. The rock drilled so far has been an unaltered diabase of adamantine character. The bits had to be re-set every five feet of drilling. Today, however, the drill penetrated a soft streak filled with iron-stained vein matter several feet in width which was probably a stringer or parallel vein to the main fault. The drill is being sunk on an incline with the dip of the vein so as to penetrate it at a depth of 600 ft. below the 660-ft. level. It will take between 60 and 80 days to finish this work.

Globe, September 3.

MARICOPA COUNTY

B. N. Weinsheim, of Colorado Springs, has secured an 18-months' lease and bond on the I.X.L. group of claims in the Vulture district, from A. J. and J. A. Kellis. The group includes five claims which have been under development for three years resulting in the opening of considerable high-grade ore.

MOHAVE COUNTY

Work on the Pilgrim group continues to expose good ore in the cross-cut and it is reported that the property will be taken over by Salt Lake interests in a short time when extensive development will be carried forward.——W. A. Mensch has installed an engine and a blower at the Enterprise mine. There is a large force at work on the ground and it is the intention of the owners to open the claims several levels below the present workings.——The shaft of the Richardson brothers at the London mine in the Union Pass district is down 100 ft. Sinking will be continued several hundred feet as the vein at this point has every indication of developing a rich orebody.——The work of getting the old mill at the Gold Crown mine in running order is well under way and it is thought that the plant will be in operation by December 1.——The shaft at the C. O. D. mine will soon reach the 400-ft. level where a station will be cut. The water in the upper levels is all being caught at the 200 where it is easily handled by the station pump. There is little water below that level and this is all hoisted in the bucket.——At the property of the Wallapai King Mining Co. the shaft has cut the vein at a depth of 110 ft. and is being sunk to the 200-ft. level where a cross-cut will be driven to the ore. It is thought that the shoot will show a high percentage of sulphide when cut below the water level as the vein in the upper portion is oxidized and assays well in gold and silver.——The new working shaft at the Ruth is progressing rapidly toward the orebody opened on the 100-ft. level by the west drift. The company has purchased the old mill of the Arizona Pyramid Gold Mining Co. and will move it to Silver creek.

PINAL COUNTY

The Maverick group of claims which was taken under lease a short time ago by the Copper Queen Consolidated Mining Co. is now being developed under the supervision of M. C. Milton. A shaft is being sunk to the 100-ft. level where the orebody will be cross-cut.

YAVAPAI COUNTY

(Special Correspondence).—J. J. Fisher reports the development to be going ahead steadily at the Little Daisy mine, in the Jerome district. A cross-cut at the 800-ft. level has recently opened a body of ore that assays well in gold with a high percentage of native copper. A large fan was installed last week to facilitate ventilation. Two shifts are at work a total of 20 men being employed.

Prescott, September 2.

YUMA COUNTY

There are about 50 men at work at the old Mudersbach mine in the Swansea district which was recently taken over by George Mitchell, and considerable ore is being shipped to the Clara Consolidated at Swansea. Two hoists, gas engines, and air-compressors have been shipped to the mine.

CALIFORNIA

AMADOR COUNTY

The Original Amador Mines Co. has filed a suit against the Amador Keystone Mining Co., asking for $150,000 damages. The plaintiffs claim that the defendants have been extracting ore from the property of the plaintiff company at Amador City since 1897 and the value of such ore reaches the sum named as damages. The plaintiffs also allege that prior to May 25 they had no means of ascertaining whether such ore was being extracted as the defendant company refused to allow an inspection of the workings.

KERN COUNTY

(Special Correspondence).—At the instance of the Kern County Board of Trade, a committee of oil men has sent to Mr. Taft, Mr. Ballinger, and the California congressmen, a telegram embracing a resolution regarding the oil-lands situation. After calling attention to the hardship and attendant financial loss caused by the present manner of allotting Government oil lands, the resolution prays that the Secretary of the Interior be asked to conform to the former ruling and settled policy of the Government ex-

tending over a period of ten years. The board made it of record also that it is opposed to any system of leasing of oil lands by the Government. Two changes in the existing laws were suggested as a cure for present evils; first, that all locations be recorded in the General Land Office, and when so recorded no other locations be allowed on that land until it can be proved that the first location is faulty; second, that the acreage to be taken by any one man be limited, violations of this provision to be punished by a heavy fine and imprisonment.

Bakersfield, September 6.

LOS ANGELES COUNTY

(Special Correspondence).—The third meeting of the Western Oil Producers' Association was held here on the evening of September 1. The meeting was representative of the oil operators throughout the State, although there were not as many present from Bakersfield and San Francisco as had been expected. Supporters of different policies entered heartily into arguments favoring their views, but there was an absence of the almost hostile spirit that has characterized the previous meetings of the association. There was evinced a desire to make concessions to the operators of the north. After discussing and voting on many motions, it was finally decided that the voting for the eleven directors of the association will be by letter; that the votes be canvassed at the next meeting to be held on the evening of September 8; that a full list of members be sent to all who have signed the membership roll; that membership rolls be sent to Bakersfield, Coalinga, and San Francisco for new signatures; and that the names of the men to be voted on for directors be selected by the meeting. During the meeting telegrams were read from the Bakersfield and Coalinga Chambers of Commerce asking for sufficient delay for the operators of the northern fields to secure representation. The membership roll now includes over 100 names and it is expected that this will be doubled by the time of the next meeting.——The statement that the Standard and Associated companies had bought the entire surplus of the Independent Oil Producers' Agency, at 30c. per bbl., is denied by officials of the agency. It is true, however, that oil is being bought in the open field for 30c. per bbl. Also, it is freely predicted that the price will go lower, although some doubt is expressed on this point by prominent operators. The drop in price was not unexpected in the face of the large production in the various fields of the State, and it appears that even a lower price would not be out of keeping with the present output.

Los Angeles, September 6.

NEVADA COUNTY

The drift at the Black Bear mine, at Moores Flat, is still in the shoot from which $5000 worth of high-grade ore was sold a short time ago. The ore was hand-sorted before it was shipped to Nevada City for reduction, and it is estimated that there is approximately $30,000 worth of milling grade on the dump. No stoping is being attempted, the ore which is being stored all coming from development. C. L. Wilson, the manager, will probably let a contract for the construction of a mill in the near future.

SIERRA COUNTY

(Special Correspondence).—The 20-stamp mill of the Sierra Buttes was started this week, and it is expected to have all 40 stamps in operation by fall. It is reported that a shoot of rich ore has just been opened. Jay C. Folsom is manager.——Paul W. Smith and J. G. Jackson, of Oakland, have obtained a bond and option on the Brown Bear group of gravel claims on St. Charles hill.——The 10-stamp mill of the Keystone has resumed. The lessees report considerable milling ore developed.——The vein at the Oak mine is being developed by an adit, which is in over 90 ft. on the shoot. The vein is 18 to 36 in. wide, and assays $20 to $30 per ton. The property was recently bonded by F. A. Gowing.——Development has been resumed at the Kate Hardy, under the direction of J. D. Beggs.——Work will be resumed at the Four Hills mine.——The Middle Yuba Hydro-Electric Co. is rapidly completing the installation of equipment at its sub-station, near Alleghany, and expects soon to commence the delivery of electric power to the district. It is understood that electricity will be received from the plant of the Bay Counties Power Co. until the Middle Yuba completes its plant on the middle Yuba river.——The Hunch Mining & Milling Co. has struck a 2½-ft. vein 485 ft. from the portal of the adit which assays $3.65 per ton.

Downieville, September 3.

TRINITY COUNTY

(Special Correspondence).—The contract for the installation of the Bonanza King power plant on the east fork of the Trinity river has been let and it is the intention of the management to have the work completed within the next six weeks. Operations will be resumed at the mine as soon as power is available.——A Butte company has had representatives examining the Davis group of claims on Ramshorn creek recently.——The Headlight 40-stamp mill and cyanide plant are nearly completed, all of the principal mill machinery being installed and eight of the thirteen cyanide tanks finished. Flume construction is well under way and power-plant construction begun. The aim is to have everything complete and running by

Removing Overburden by Sluicing.

November 1.——The Golden Jubilee has started a force of men on development.

Carrville, September 6.

TUOLUMNE COUNTY

(Special Correspondence).—Not in many years has the water supply in this county been as low as at present, the consequence being a compulsory suspension of operations, partly or entirely, at almost all the mines not equipped with electric or steam-power plants. In many of the mines development will be carried on with small crews throughout the dry season. The construction of a wagon-road into Knight's Creek district, which is becoming well known as a most promising mining region, is a probability of the near future. Packing on the backs of mules being the only means of transportation, the advancement of the district has been greatly retarded. Much mining machinery will be taken in as soon as transportation facilities are made better.——The machinery for a 10-stamp mill and a large electric motor have been delivered at the Duffield mine, near Arastraville. The work of erecting the necessary buildings has been commenced.——It is said that ore assaying over $100 per ton is being extracted from the Hazel Dell for shipment to Selby. The vein is 3½ ft. wide. An ore-roasting plant is being installed.——The mine at Italian Camp, operated by Rolleri & Co., is being equipped with a 4-stamp mill. A sufficient supply of ore is ready for stoping to keep the mill in continuous operation for many months.——It is reported that a body of rich ore was uncovered in the Tarantula mine last week.——The old Ham & Barney mine is about to be re-opened.——The Springfield Tunnel & Development Co. is extracting and washing some rich gravel from its property at Springfield, and the outlook is good for a most prosperous future. Sixteen men are employed.

Tuolumne, September 6.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A streak of ore has been uncovered on a vein parallel with the Virginia City on Lincoln mountain, that shows an assay value of 40 oz. gold per ton. The discovery was made by J. W. Crandall.——Ed. Stensen, of Denver, who recently purchased the Oriental group of claims, states that machinery will be purchased this fall.——John Hurley, leasing on the Helen-Herold property in the Daily district, has uncovered an 8-in. streak of ore that is worth 300 oz. silver and 5 oz. gold per ton. Shipments will start in two weeks.——Power drills are working in the breast of the Vidler adit in East Argentine. C. A. Fuller, the contractor, will complete the 2300 ft. of driving inside of eight months.——A rich discovery has been made in the heading of the Silver Plume adit on Leavenworth mountain.——Work was put under way this week in the development of the Ruler mine on Griffith mountain. The adit is to be driven for a long distance as a number of cross-veins are owned. N. Williams is manager.——E. Relhling, leasing on the Freighters' Friend, is stoping on a streak of ore two feet wide that mills $26 per ton in gold and siiver.——The main shaft on the Avalanche mine at Freeland is to be sunk 100 ft. E. M. Moscript is owner.

Georgetown, September 3.

LAKE COUNTY

The work at present in the Birdella adit in Gleason gulch in the Leadville district is moving slowly on account of the heavy flow of water that is coming from the breast of the cross-cut which is being driven to tap the Amity shaft. The water in the shaft has already been lowered 15 ft.——The heavy flow of water in the Wolftone shaft is under control and the pumps are now handling 1500 gal. per minute. ——The water has been lowered to the 650-ft. point in the Helena and it is probable that development will be started at this point.——Miles Lee and associates who have a lease on the North Star No. 2 have cleaned out and retimbered the adit and are working on a streak of ore which was found in the face of the drift.——Robert Jones, leasing on the Robert E. Lee, is stoping on a large body of ore which he has opened on the lower levels, and is shipping a lead-zinc product.——The shaft on the Clear Grit is down 120 ft.—— Diamond-drilling has been resumed in the Hilltop mine.

OURAY COUNTY

Another rich vug has been opened on one of the Wanakah Mining Co.'s claims, and the ore is being sacked before sending to the mill. Over 100 tons have heen shipped from the vug that was opened a short time ago, assays of over $100 per ton being obtained.

TELLER COUNTY

The School Section Leasing Co., operating on Bull hill in the Cripple Creek district, has been shipping a carload of ore per day since the first of the month. The ore is coming from the fifth level and there is enough broken to keep up this rate for the next three months.——One of the best discoveries made in the district recently was that of Robert Edson, in the Findley mine, the coarse rock milling $40 per ton, and the screenings $90. The ore is between three and four feet wide.——The Jerry Johnson mill, on Ironclad hill, has been closed on account of the litigation between the Jerry Johnson company and Edwin Gaylord.

KANSAS

CHEROKEE COUNTY

(Special Correspondence).—In spite of the fact that a large surplus of ore has accumulated in the Galena camp awaiting a higher market, the mines are not closing, but many new prospects are being constantly opened and old mines resuming activity. Among the larger properties operating are the New Century, the Diplomat, the Abbey & Co., the James Murphy, and a number of small plants from 5 to 50 tons. The Diplomat has sunk to the 180-ft. level, a depth greater than hitherto worked on this land, and has found a fine run of ore of the typical boulder type. The mill is working on a dump pile which contains about 6000 tons of material, accumulated during the building of the mill.——The Wyandotte company has made one of the richest discoveries of recent date in the camp, having found ore which makes a recovery of 20%. Out of 400 tons mine run 90 tons of ore was secured. The deposit was struck at 50 ft. and occurs in a flint gangue with a large amount in the fine dirt distributed through the boulders. All the ore in sight is thought to run 20%. The company has also sold a lease of 20 lots to a large company on the west side of the land and this will be developed at once. This part of the land has yielded a large amount of ore from shallow gouges in the past but will be developed at the lower runs.——Another rich drill-hole has been recently completed by the Clermont company, in the southwest part of the camp. The ore was found at 225 ft. but was richest at a depth of 250 ft. with the drill still in ore at 276 ft. The work was stopped at 280 ft. Another hole will be drilled a short distance from this one. The hole first put down and completed a few weeks ago was almost identical with the second one just reported.——The New Century, the largest mill in Galena, is again operating, though only a part of the mill is used. The plant was originally a double structure. Two shafts are used to supply the mill and some ore is brought from other leases.——A drill-hole has been put down on the Glick land by J. C. Moore, and the drill entered ore at 72 ft. continuing in ore to 80 ft. The cuttings ran 10% and were higher grade than most of the ore taken from this land. Seven drill-holes have been sunk, five of which showed excellent ore while the other two showed only very thin seams and were called blanks. The best hole so far sunk showed a face 18 ft. thick.

Galena, September 3.

MISSOURI

JASPER COUNTY

(Special Correspondence).—Among the good discoveries recently is one by the Waneta company on West Seventh street, Joplin, where the drill passed through a rich run of ore at a depth of 127 to 137 ft. The ore ran 6% zinc. This mine has been worked for a number of years, at various depths, beginning at 70 ft. and afterward being deepened to 100 and later to 131 ft. The mines to the south of this property have been working at depths between 180 and 200 ft.; and additional prospecting will be carried on by the Waneta to discover ore at these lower levels.——The second drill-hole has been completed on the Brattleboro lease on Turkey creek, and has entered the same ore deposit which was reported in the first. The ore was struck at 63 ft. continuing in soft ground till 83 ft. when a hard limestone was entered. The ore is exceedingly rich, running 35% zinc in places and consists of the same quality as has been mined successfully in the Kalitan and Cardinal tracts adjoining.——Northwest of Webb City the second hole has been sunk by a party of Webb City and Joplin men, and has been successful in finding a fair run of ore from 164 to 194 ft. The first hole reported a few weeks ago was similar to the second.——The Granby company, which has undertaken development of its mining grounds in the Oronogo camp, has outlined a new plan by diverting the stream which flows through its land into a new channel to prevent constant flooding of the ground.——The drifts of the Oronogo Circle No. 3 which have hitherto been producers of the highest grade zinc ores, running less than 0.5% lead and bringing the highest market price, have recently completely changed from zinc to lead producers, and have thus vitiated the zinc ores while the lead value has increased remarkably. Two of the drifts show a complete lead face while the third contains much lead mixed with the zinc.——Among the new mills to be erected recently is the Muskingum plant on the west Joplin disseminated tract. It is a 250-ton plant brought from the Peacock district where it was used a short time. The lease consists of 20 acres of well developed mineral land, surrounded on three sides by good producers.

Joplin, September 3.

MONTANA

SILVER BOW COUNTY

(Special Correspondence).—The Black Rock shaft of the Butte & Superior Copper Co., has reached a depth of 1600 ft., and ore is being hoisted from the 1000, 1200, 1400, and 1600-ft. levels, the work of establishing levels at 900, 1100, 1300, and 1500 ft. being in progress. The shaft starts in the south wall and cuts through the vein at a depth of 700 ft., then re-crosses it again at 1400 ft., which indicates the variation in the dip of the orebody. Development on the strike of the vein extends 600 ft. west, and 300 ft. east of the shaft. It is asserted that the greater bodies of ore lie in that portion of the vein east of the shaft. The vein, known as the Black Rock lode, has an approximate width as reported of 250 ft., the ore occurring in lenticular bodies. These lenses have a width varying from 10 to 55 ft., and some of them have a length of 300 to 500 ft. The gangue consists of quartz and decomposed granite, containing zinc sulphide, with some iron, manganese, copper, lead, silver, and gold. The ore runs, usually, 20% zinc, 1 to 2% lead, 6 oz. silver, with traces only of copper and gold. The output of the mine is limited to the capacity of the concentrating plant at Basin, or that portion of it that is under lease to this company, 330 tons per day. Two concentrate products are made; the first and principal part assaying 51% zinc, 3% lead and manganese, and 14 oz. silver. This is shipped to the plant of the Bartlesville Zinc Co., in Oklahoma, controlled by the American Metal Co.; the other product, containing 40% lead, 17% zinc, 10% iron, and 25 oz. silver, is marketed locally. The lead product amounts to 1¼ tons per day. On the whole, the concentration is at the rate of 3½ tons into 1 ton; the recovery of zinc reaches 70%. M. W. Atwater, superintendent for the company, states that the work of erecting and installing a concentrating plant of 1000 tons capacity at the mine will proceed this fall. The building will be of steel, and will house equipment for jig and table concentration, and for classifying, and settling the slime. There will be no magnetic machines, as the ore is low in iron. Four carloads of structural steel are now on the ground for the building. Hoisting is done by running the loaded cars into the cages, but this method is to be supplanted at once by using 3½-ton skips, there being two hoisting compartments for ore and one for a cage that carries men, timbers, and steel. There are two air-compressors, one steam and one electric driven, having the capacity to operate 16 drills. The intention is to run the new mill by electric power.

Butte, September 3.

NEVADA

ESMERALDA COUNTY

Arrangements have been made with the management of the Goldfield Consolidated for the development and working of the shoot in the Vinegarone ground of the Jumbo Extension, as the ore has been opened in the Consolidated stopes to the boundaries of the Vinegarone claim. The workings on the Consolidated side of the line have produced over $2,000,000.——A shipment of 50 tons of ore assaying $35 to $40 per ton was forwarded recently from the Nevada Eagle mine to the sampler of the Western Ore Purchasing Co. The ore was mined on the 250-ft. level where a large tonnage has been opened. The ore nearer the surface was inclined to be erratic, the value depending on rich stringers, but with depth these have widened and the whole vein is now of fair grade.——Plans are being formulated for the reorganization of the Goldfield Daisy, and if carried through a new corporation will be formed to reopen the property.

HUMBOLDT COUNTY

The new machinery, consisting of a 15-hp. engine and a pump, for the Wild Bull Mining Co., in Wild Horse, has been forwarded from Lovelocks to the mine, where it will be installed in the course of a few days. The shaft, now down 265 ft., will be sunk to the 400-ft. level as soon as the installation is complete, and a cross-cut driven to the ore.

NYE COUNTY

(Special Correspondence).—E. B. Bennett has placed orders for equipment for the Beatty Extension mine. The main shaft is down 60 ft. and will be carried to depth to open several veins disclosed in surface workings. A body of ore in the bottom of the shaft assays $4 per ton.——The enlarged mill of the New Bonnie Clare Co. will be started shortly. The spur line from the Las Vegas & Tonopah railroad to the mill ore-bins is being rushed to completion. ——It is reported that work will be resumed within a short time at the Luiu Mac group. John Lindstrum is manager.——The lessees on the Diamond recently shipped a car of high-grade ore to the Martinez plant of the Mountain Copper Co.——Vucovich & Gingles have received returns from a recent shipment of 30 tons of ore to the Needles smelter, from their Denver lease on Tramp Consolidated. The ore averaged $49 per ton.——The Eclipse mill is running on ore from the Shively-Bennet lease on Tramp No. 5 claim. The ore assays $47 per ton.——The management of the Johnnie Consolidated mines has decided to sink the 800-ft. incline shaft to a depth of 1000 ft. from which north and south drifts will be extended. It is also planned to sink a new shaft, 3000 ft. south of the present workings, increase the capacity of the mill from 75 to 100 tons per day, and erect a power-plant at Amargosa station. The new shaft will probably be vertical and 600 ft. deep.——The shaft of the Mizpah Extension has reached the 900-ft. point and will be continued to the 1000-ft. level before lateral work is undertaken. The formation has grown harder, rendering sinking more difficult. ——A foot-wall cross-cut has been started from the 500-ft. level of Tonopah Extension to open the orebodies developed in the west part of the 400-ft. level.

Rhyolite, September 2.

STOREY COUNTY

Assays of $82.50 have been obtained from the face of the drift started a short time ago on a stringer intersected by the east cross-cut of the Mexican mine, the vein having widened to 8 in. Shipments of 50 tons per day are being maintained.——Rich ground is also being opened in the Ophir, 37 mine cars being hoisted that assayed $141.74 per ton.——Cross-cut No. 2 on the 1200-ft. level of the Overman has been cleaned up and work resumed in the face.——Mining in Sixmile canyon is progressing satisfactorily. The Comstock-Phoenix at the north end of the Brunswick lode is shipping steadily to the Butters mill though no stoping is being done, the ore coming entirely from development. Repairs have been made to the aerial tram of the Butters company.

WHITE PINE COUNTY

A new Cameron No. 9 pump has been ordered for the Zack shaft of the Ely Consolidated Copper Co., and sinking will be continued. A large tonnage of ore assaying 5 to 7% copper has been blocked out in the upper levels and lateral work will be started from the shaft to develop this at depth as soon as the pump is in position.——It is reported that Salt Lake interests have secured an option for $25,000 on the Gold Coin group which joins the holdings of the Nevada Consolidated.——R. H. Richardson and John Eager have secured a bond on several claims in the Patterson district which are supposed to contain valuable gold and tungsten ore. Samples have been taken and work will be started on the property if the assays prove as rich as expected.——Machinery is being forwarded from Ely to the Hub properties where work has commenced on the mill. Construction is under the supervision of E. L. Fletcher.——Nickerson & Johnson shipped a car of lead-silver ore from the Elijah mine, near Lane City, which they are working under lease. The ore was sent to the American Smelting & Refining plant and is valued at $30 per ton.——O. H. Paulson, who re-located the old Ruby Hill group about a year ago, has obtained samples from the property that assay several thousand ounces of silver per ton. The group is in the Schell Creek district about forty miles from Ely, and was opened in early days when a large amount of high-grade ore was shipped.

UTAH

BEAVER COUNTY

A mill and cyanide annex that will treat 20 tons of ore per day is to be erected at the Rob Roy property on Indian creek, the controlling interest of which is held by P. T. Farnsworth, who has been directing the development for some time. A new shaft has been started across the creek which will be sunk on the vein. Work is to be resumd shortly on the Busy Bee ground which adjoins the Rob Roy.

JUAB COUNTY

Work has been started at the Black Jack mine in the Tintic district, a contract having been let for 200 ft. of driving. This work will be directed toward the Opohongo ground where the Opohongo shoot is supposed to enter the Black Jack property.——The shaft at the Victoria was sunk 130 ft. the past month, giving a total of 750 ft. The work is progressing in a satisfactory manner and it is expected that the objective point, the 1000-ft. level, will be reached within the next two months.——A pocket has been cut at the 650-ft. level of the Dragon shaft and sinking has been resumed. About 30 carloads of ore per week is being shipped from the mine.——New equipment has been purchased for the Crown Point and will be installed at an early date. A new shaft 1300 ft. east of the Colorado No. 2 shaft has been started.——At the Eagle & Blue Bell 239 ft. of the new shaft was cut during August, and it is expected to complete the remaining 200 ft. by the end of this month, making connection with the 1000-ft. level and giving the company excellent ventilation. The new hoist will be started as soon as the connection is made.——The Bullock Mining Co. has levied an assessment of 1c. per share on its outstanding stock which becomes delinquent October 1 with the date of sale set at October 18.——Work has been started through the Iron Blossom 500 and 600-ft. levels developing the adjoining Governor property into which the Iron Blossom orebodies extend.

SUMMIT COUNTY

The long adit of the Silver King Coalition Mines Co. has been straightened and electric wires for power haulage strung. It is reported that a new shoot of galena three feet wide has been opened on the 1200 and 1300-ft. levels of the mine.——H. M. Crowther and associates have secured another long lease on portions of the old Ontario mine, and are preparing to increase the working force at the property. ——Joseph M. Howells is at the head of a new company which has been formed to absorb the Park City Mines & Power Co. owning the Baby McKee group in the Cottonwood district. Rich ore has been blocked out in the property and shipments will be started at once.——Over 1100 ft. of the Snake Creek-Daly-Judge tunnel has been completed during the past three months though a slight delay was caused a few weeks ago through the late delivery of air-pipe.—— The fissure on the 800-ft. level of the New York is reported to be improving, a number of rich pockets of ore having been opened recently.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—Work has been resumed on the Blue Bird mine in the south belt of the Rossland district. A small force has been started on development and results have been gratifying. One assay taken from a recently opened deposit showed 2 oz. gold, 10 oz. silver, and 5% lead per ton. Considerable concentrating ore is being mined and placed on the dump.——The Le Roi Mining Co., which has gone into voluntary liquidation, is said to be practically free from debt. There is no mortgage against any of the company's property and no debentures have been issued. Last year the company borrowed $77,760 and expended $145,800 since the reopening of the mine, part of which sum was derived from the sale of ore. Of the amount borrowed, $77,760, $24,300 has already been paid and there is about $38,000 cash on hand and owing the company by the smelters and others, leaving a difference of $14,660. This company has done 27,000 ft. of diamond-drill exploratory work since June, 1906; 15,000 ft. of this having been done during the last 12 months. The last of the known pay-ore is being taken out of the mine and will be realized upon. It is estimated that it would take approximately $500,000 to effectively explore the Le Roi ground for more ore of the better grade. There is a lot of second-class ore still in the stopes of the mine, which is considered a valuable asset.——It is stated that arrangements are being made by the Ymir Gold Mines, Ltd. to sink 500 ft., or more, on the main vein, from the tenth level.——In a recent statement William Templeton, the Minister of Mines, made it known that one of the best zinc experts in the world was at present gathering data relative to electric-zinc smelting in those countries where it is now practised, with a view to perfecting a system for the treatment of Kootenay zinc ores. All possible information will be secured and laboratory tests made at Ottawa, and when the scheme has been advanced to a commercial stage the final tests will be made at the electro-thermal smelter at Nelson. The $50,000 recently appropriated for this purpose is being used with care and it is hoped that a successful method of treating the local zinc ores will be the outcome.

Rossland, September 3.

ONTARIO

The Temiskaming & Hudson Bay Mining Co. paid dividend No. 27, August 27, amounting to $23,263 or 300% on the issued stock. The company is erecting a new mill, the fourteenth in the camp of Cobalt, and has the foundations well under way, with the machinery ordered.——From 30 to 40 tons of ore per day are being run through the concentrator at the Savage property, and five drills kept in operation underground. Practically all the work is confined to the 80-ft. level, although the main shaft is down 140 ft., with two veins opened that vary between one and two inches in width and assay 1200 to 1500 oz. silver per ton.——The Harris Lorrain Syndicate has opened a promising vein of calcite containing smaltite and nicolite in trench No. 1 on its property in the South Lorrain district.——Two new orebodies have been cut underground in the Beaver mine which assay about 5000 oz. silver per ton and greatly add to the company's ore reserve. The first discovery was made by raising in an old stope on the 200-ft. level and the second in the cross-cut on the 300.——A four-foot vein has been uncovered several hundred feet on the claims of James Hylands at Porcupine, and a two-stamp mill is to be erected on the property.

MEXICO

CHIHUAHUA

D. W. Shanks, general manager for the Rio Plata Mining Co., who has been in New York recently, stated that the property which is in the Arteaga district was in excellent condition. About 1200 ft. of drifts have been driven since January 1 on the vein of silver ore. A new tube-mill has been installed and the company is treating ore that assays as low as 17 oz. per ton silver. A shipment of 52 bars of bullion containing 58,000 oz. silver has been recently forwarded to Chihuahua.

PHILIPPINES

The mill at the Mauricio mine in the Paracale district started the latter part of August, the tram line to handle fuel having been completed. An ample supply of fuel and water has been provided for and a great deal of interest is taken in the property as it has been one of the pioneers of the district and its success means much to the surrounding country.——The shaft at the Tumbaga is nearing the second level and it is expected that the station at the 200-ft. point will be cut this month and the drifts well along on the vein by the next.——The Ragay Gulf Exploration Co. has been incorporated to develop a number of copper claims and a large area of dredging ground.——There are now three dredges operating in the Paracale district and if the plans of the operating companies are carried out there will be two or three more at work before the end of the year.

Universities and Mining Schools

D. Dale Condit has been appointed assistant in geology for the ensuing year in Columbia University.

University of Wisconsin senior mining students spent six weeks during the past summer at the Butte mines. The course included surveying, mapping of field geology, and underground work.

Clinton R. Stauffer has been appointed assistant professor of geology in Queen's University, Kingston, Ontario. This position carries with it an appointment on the Canadian Geological Survey.

The American Society of Engineering Contractors will hold its annual convention at the Coliseum, St. Louis, Missouri, September 27, 28, and 29. D. J. Hauer, 13-21 Park Row, New York City, is secretary of this Society.

Frank Koester, in a paper presented before the recent Convention of the Society for the Promotion of Engineering Education, held at Madison, Wisconsin, discussed in detail the educational system of the German technical universities.

The University of Chicago included in its summer courses a number of lectures on conservation. The speakers included C. W. Hayes, chief geologist of the United States Geological Survey; Frederick H. Newell, director of the Reclamation Service; and Henry S. Graves, chief forester.

The bulletin of the Lewis Institute has been issued. It contains the announcement of courses, lists of students and officials, and general information. The work is divided into three main parts; engineering and the mechanic arts, domestic economy, and liberal arts. The regular course covers a period of four years and the autumn quarter commences September 26.

The June issue of the quarterly bulletin of the University of Missouri School of Mines and Metallurgy contains the commencement address delivered by Charles Sumner Howe June 1. Mr. Howe, who is president of the Case School of Applied Science, spoke on the success that has to do with individual traits, and the success that is concerned with the highest good to the Nation at large.

At the University of California an association has been formed by the professors and students under the direction of F. G. Cottrell, for the study of the smelter-fume problem. Data regarding the removal of injurious substances from the smoke and the commercial disposition of the by-products will be collected, and experimental work carried on in the laboratories. In the work of determining the availability of the by-products as sterilizing and fertilizing agents to the soil the College of Agriculture will assist, with the College of Mining contributing to the metallurgical side.

The Michigan College of Mines, at Houghton, has issued its 'Year Book for 1909-1910,' 'Views of the Michigan College of Mines,' and a list of its graduates. The Year Book contains the announcement of courses for 1910-1911, lists of the faculty, students, and accredited schools, requirements for admission, costs of living, regulations, prizes, and scholarships. In addition to these, maps of the campus, Portage Lake mining district, and the mineral district of northern Michigan have been included. The views of the college show the buildings, laboratories, and field courses taken by the students. The list of graduates contains the names of 522 former students with their records and addresses. The term opens September 30.

In keeping with its progress in welfare work, the Dodge Manufacturing Co. has just opened to employees of the big plant at Mishawaka, Indiana, an athletic field fully equipped for tennis, croquet, quoits, bowling on the green, and horse shoes. Surrounding the field is a system of tungsten drop lights affording facilities for indulging in the various sports after dark. It is pleasant to see this evidence of co-operation between employers and employees.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Phillip N. Moore is in San Francisco.

Courtenay De Kalb is at El Cobre, Mexico.

John M. Nicol was in Zacatecas last week.

James Breen has returned to Spokane from Judith Basin, Montana.

George A. Packard is making Butte, Montana, his temporary headquarters.

T. Lane Carter, of Chicago, is on a professional trip through Kansas and Missouri.

Albert Burch leaves San Francisco today for a month's work in British Columbia and Alaska.

S. E. Robbins has returned to the Fremont Con. Mines at Drytown, California, from Costa Rica.

J. W. Astley has resigned as consulting engineer for the Peterson Lake Mining Co., at Cobalt, Ontario.

Hallet R. Robbins, of Seattle, is examining mining properties in the neighborhood of Haines, Alaska.

E. H. MacDonald, field geologist for the Northern Pacific Railway Co., spent a month in the regions tributary to Pierce and Elk City, Idaho.

Arthur W. Jenks sailed from London, August 19, to take his position as resident manager of the Famatina Development Corporation, Ltd., Chilicitos, Argentine Republic.

W. Weston has resigned as chief of the mining and industrial department of the D. N. W & P. R. R., and opened an office in the Gas & Electric building, Denver, Colorado, for consulting work in mining and industrial engineering.

The San Francisco Section of the Mining & Metallurgical Society met following dinner at the Palace Hotel, September 5. The following members and guests were present: S. B. Christy, F. W. Bradley, M. L. Requa, C. W. Merrill, W. S. Noyes, A. C. Lawson, Albert Burch, Francis Drake, H. F. Bain, Stuart Rawlings, Charles Janin, Howard D. Smith, E. H. Garthwaite, Sumner S. Smith, F. G. Cottrell, William M. Rees.

VOGELSTEIN TIN CIRCULAR

The statistics of tin stocks are disappointing to those who expected to find in them some reason for the recent advance. They are quite commonplace, showing only the normal shrinkage of the visible supply usually witnessed in a non-Banca sale month, about 1000 tons, bringing the total stock landed and afloat to approximately 16,500 tons. Straits shipments are liberal, 5400 to 5500 tons, about 700 tons larger than the same month last year, but for the eight months there is still a deficit of nearly 2000 tons from this source. European deliveries show no striking change. The most notable development is the continued increase in U. S. deliveries, which now amount to 4300 tons more than last year. There has, however, undoubtedly been a record-breaking actual consumption of the metal. The question now is as to whether consumption may be expected to continue on the same scale. As to the future it seems safe to assume that deliveries will be good during the next month or two, but that thereafter some falling off may be expected in harmony with the curtailment experienced in other lines of the metal trades.

L. Vogelstein & Co. give the following figures of German consumption of foreign copper for the months January to July, 1910:

	Tons.
Imports of copper	100,150
Exports of copper	5,058
Consumption of copper	95,092

as compared with consumption during the same period in 1909 of 90,168 tons. Of the above quantity 86,684 tons were imported from the United States.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

EFFECT OF PERFECTED LOCATION

A perfected location of mineral land has the effect of a grant by the United States of the right of present and exclusive possession. Accordingly where a locator who claims under a prior notice of location, with the boundaries of his claims sufficiently marked, does the amount of required work on the claim and records a sufficient location certificate, any inchoate rights by a rival claimant under an attempted subsequent location of the same claim thereby comes to an end and will not be revived by an subsequent forfeiture or abandonment of a senior location.

Bergquist *v.* W. Virginia-Wyoming Copper Co., (Wyo.) 106 Pac., 673, Feb. '10.

INJURY TO MINER—SAFETY OF 'TRAVELING WAY'

A part of a mine in which a miner was working that was designed for a passage way when completed, but which was only partly completed, was not a 'traveling way' within the meaning of the Colorado statute which requires mining companies to timber such. But it was the duty of the mine owner and operator to furnish the necessary timbers to support the roof and his duty to exercise ordinary care to furnish a reasonably safe place for the miner to work, and the miner only assumed the risk of those dangers which are known to him or which are plainly observable. He has a right to assume that the master has performed his duty and it is not incumbent upon him to discover unknown dangers which are not plainly observable.

Baldi *v.* Cedar Hill Coal & Coke Co., 173 Fed. 781.

EMINENT DOMAIN—OBTAINING IRON DEPOSITS FROM A PUBLIC CEMETERY

The fact that private parties were interested in securing the vacation of an old cemetery in order that the ground might be mined for iron, and the fact that they agreed to bear the expense of moving the bodies and the monuments to a new cemetery provided by the iron company did not affect the question of the necessity of appropriating the land sought to be acquired under regular condemnation proceedings.

McDonald *v.* Marquette Circuit Judge (Mich.) 123 Northwest. 112, Dec. '09.

INJURY TO PERSONS SEEKING EMPLOYMENT IN A MINE

A person applied to a pit-boss for a position to work in a mine, and was requested by the boss to return on a subsequent day. Pursuant to the request at a later day and on application on the office was directed by the superintendent to the pit-boss as the person who knew when men were needed, and thereupon went to the tipple of the mine to see the pit-boss, and while there was injured by an explosion which occurred in the mine. On this state of facts it was held by the Supreme Court of Michigan that whether such injured person was there on express or implied invitation was a question which must be submitted to a jury and could not be determined as a matter of law.

Schmidt *v.* Michigan Coal & Mining Co., (Mich.) 123 Northwest. 1122, Dec. '09.

RIGHT OF TENANT TO OPEN AND WORK MINE

A tenant by the courtesy has no right to open and work a coal mine which was unopened and unmined at the time of the death of his wife, though, as coal in place is held to be land, he has a life estate in it with which estate the remainderman cannot interfere. And where such tenant by the courtesy and the remainderman together sold all their interest in the land, including the unopened and unused mine, the proceeds stood in the place of the land and the tenant by the courtesy was entitled to the entire income during his life.

Deffenbaugh *v.* Hess, (Pa.) 74 Atl. 608.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

OUTLINES OF GEOLOGIC HISTORY. By Bailey Willis and R. D. Salisbury. 8vo. Pp. 306, Ill. University of Chicago Press, 1910. Price $1.50.

This book includes a series of essays involving a discussion of geologic correlation presented before Section E of the American Association of the Advancement of Science at Baltimore, December, 1908. The symposium was organized by Mr. Willis and the book has been compiled and edited by Mr. Salisbury. The contributors include many of the leaders of American geological work and the symposium was the most comprehensive attempt to summarize the known facts relating to the geologic history of North America since the publication of the well known correlation essays of the U. S. Geological Survey nearly twenty years ago. It is an especially welcome addition to the library, particularly of those who wish to know the recent interpretations of American geology but who have neither the time nor facilities for consulting original sources. It is compact, authoritative, and up to date. It is to be regretted that more of the discussion of these interesting papers was not included so that certain divergent views might also be presented. The most important omission, however, was that of a summary chapter by either or both the authors. The non-professional reader in particular would have been greatly helped by such a chapter, which both Mr. Willis and Mr. Salisbury are so well qualified to prepare. None the less the book is an important and most serviceable contribution.

A MANUAL FOR ASSAYERS AND CHEMISTS. By W. H. Seamon. Pp. 255, Index. John Wiley & Sons, New York, 1910. Price $2.50.

It goes, almost without the saying, that this work of Mr. Seamon's is one well worth while. The author says in his preface that the book is principally for students and young graduates of mining schools, brought face to face with problems which ordinarily can only be solved after many years of experience. In addition to the well known standard methods, the author has added several which are distinctly original with him—methods which bring results. Mr. Seamon was for several years director of the State School of Mines at Rolla, Missouri, and at another period, president of the School of Mines, at Socorro, New Mexico, and was later the founder of the well known Seamon Assay Co., at El Paso, Texas. He has in recent years been established at Chihuahua, Mexico.

MINES OF RHODESIA. By Owen Letcher. Mining editor *South African Mining Journal.* Pp. 452, Ill., index. *South African Mining Journal,* Johannesburg, publishers.

This volume contains much of value to all interested in the development of Rhodesia, in whatever field. It treats of the geology of the region; the mining laws; the various mining divisions and mines, and their rapidly progressing development; together with a great deal of information for the use of settlers, with chapters on educational advantages, cattle raising, and agricultural possibilities, and with reliable statistical information. Several maps accompany the book which are a valuable aid in reading its contents. It is a much needed volume and will be heartily welcomed.

SEWERAGE. By A. Prescott Folwell. 8vo. Pp. x + 506, Ill., index. John Wiley & Sons, New York, 1910. Price $3.

A new, sixth, edition of this well known and standard text is now available. Important additions have been made and the entire text as relates to theory and practice has been brought up to date. Designing and construction methods, specifications, and the use of concrete in sewerage works is treated with especial fullness. The book will be useful not only as a class text book but for general reference.

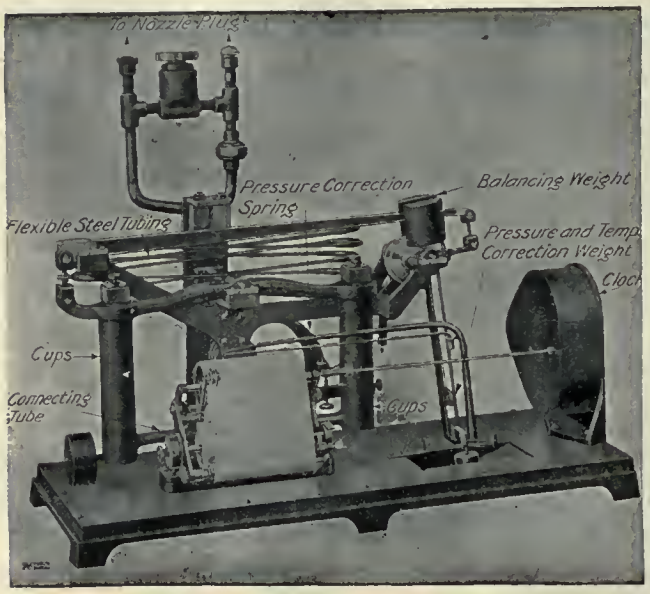
DIVIDENDS

On Saturday, September 3 the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 156 of $98,100. This makes the amount of dividends paid since January 1, 1910, $745,500, and the total to date $12,031,500.

A STEAM AND AIR FLOW METER

Over a hundred years have passed since James Watt perfected a steam engine with practical operating qualities, yet up to the present time the engineer has had no means of knowing how much steam was being delivered to the prime mover—how much utilized, how much wasted. The engineers of the General Electric Co. became impressed over four years ago with the fact that a means of doing away with guess-work in handling steam would be a wonderful boon to the engineering world. Experiments were undertaken with a view to perfecting a practical steam-meter, and as a result of over a thousand actual tests such an instrument is now on the market. There



Recording Steam Flow Meter, Showing Automatic Pressure Correction Device.

have been developed a recording steam flow meter, two types of indicating steam flow meters and an indicating air flow meter, each of which will accurately measure the rate of flow of steam, air, or other gases, in any size pipe, under any conditions of pressure and temperature met in commercial practice. The principle governing the action of the flow meter is a modification of that of the Pitot tube. A brass nozzle plug, screwed into the pipe at the point where the flow is to be measured carries two sets of openings: a lead-

Nozzle Plug.

ing set, facing the direction of flow and extending diametrically across the pipe; and a trailing set, consisting of two openings at 90°, and one at 180°, to the direction of flow. The impingement of the steam against the leading openings sets up in them a pressure equal to the static pressure plus the pressure due to the velocity head, while the trailing set is acted on by the static pressure less that due to the velocity. The difference is a measure of the velocity, and for constant temperature and pressure, gives the rate of flow. The pressures existing in the two sets of openings are communicated through separate longitudinal tubes to the outer end of the plug and from there by ¼-in. iron pipes to the meter.

The recording steam flow meter, Type R, form D, is a curve drawing instrument, accurately calibrated to record the total rate of steam flow in pounds per hour. In this meter there are two cylindrical hollow cups filled to about half their height with mercury and joined together at the bottom by a hollow tube. This U tube is supported on and free to move as a balance about, a set of knife edges. The two pressures obtained by the nozzle plug are communicated to the cups by flexible steel tubing, whereupon the difference in pressure is equalized by a rising of mercury in the left-hand cup and a falling in the right-hand cup. Because of the displacement of the mercury, the beam carrying the cups tilts on the knife edges until the moment of the counter weights on the extreme right of the meter exactly balances the movement caused by the displacement of the mercury in the left-hand cup. The motion of the beam is multiplied by levers and is registered by a pen. The time element of the meter consists of an eight-day clock driving a drum and feeding paper at the rate of one inch per hour. Charts are supplied in sizes to measure a flow of from 2000 to 240,000 lb. per hour, and of sufficient length to last one month. The rate of flow can be read at any instant or the average rate of flow calculated for a given time.

A NEW CRUSHER

The long felt demand for a crusher which will not only successfully crush but grind in the same operation is claimed to have been filled by the 3-B Eureka Crusher manufactured by the Eureka Stone & Ore Crusher Co., Cedar Rapids, Iowa. This machine is of all steel construction, the base being a single open-hearth casting which gives the required rigidity and strength. It will resist the most severe crushing shock. The jaw plates are made of the highest grade of manganese steel and are made reversible so that the maximum of use may be obtained. The eccentric shaft which carries the weight of the movable pitman is turned from a single open-hearth, hand-forged, steel casting, the bearings being made extra large to prevent excessive heating. The best grade of babbitt metal is used throughout. There are only three bearings in the complete machine, thus cutting down the friction fully 50% and saving from 25 to 40% in power. This 3-B crusher will reduce from 3 to 4 tons per hour of 3-in. rock or ore to the fineness of sand. It requires approximately 12 to 15 hp. A hand wheel regulates the distance between the jaws so that the product can be had in any size from 2½ in. down to sand. It is not necessary to stop the machine to change the size of the product. The safety toggle-plate prevents possible breakage from the accidental dropping of a hammer between the crushing surfaces. The tensile strength of this toggle is measured against the base of the machine. Exclusive of bolts the crusher has only fourteen parts. It practically combines the work of two machines in one. The Eureka Stone & Ore Crusher Co. is distributing some literature describing this machine and fifteen others.

COMMERCIAL PARAGRAPHS

PARROTT & Co., San Francisco, has recently been appointed Pacific Coast representatives for the Insoloid Fuse Company.

THE GALIGHER MACHINERY CO., Salt Lake City, has recently received an order for 1500 Isbell vanners to be used in concentrating mills of the Ray Consolidated Copper Co., and the Chino Copper Co. It is said to be the largest single order for concentrating machines ever placed.

The WESTINGHOUSE ELECTRIC & MANUFACTURING Co. has recently received an order from the La Blanca & Anexas Mining Co. for 40 type MS motors to be used in the company's mill at Pachuca, Mexico. The motors ordered range in size from 5 hp. on the pulp thickeners to 75 hp. on the tube-mills.

THE GREAT WESTERN MACHINERY CO., Denver, advises that it has purchased and now has for sale all the machinery from the Bamberger De Lamar 500-ton cyanide mill at Callente, Nevada. Among the items may be mentioned motors aggregating 1000 hp., in units of 5 to 100 hp., 75 tanks, 10 Chilean mills, Gates crushers, Blake crushers, several electric locomotives, 5 miles of light rail, 32 miles of pipe-line, and numerous small machines and tools.

TABLE OF CONTENTS

EDITORIAL

ROBBERY of the safe on the steamer *Tanana* transporting bullion on the Yukon river, calls attention to the great sums of gold now regularly transported from Alaska to the States without loss. In the old days the fleet of treasure ships would have needed a corresponding fleet of battleships. Now robbery is only possible by connivance of some responsible official as is suspected in this instance.

ITALY is to be the host of the Tenth International Geographical Congress, which will assemble at Rome, October 15, and continue in session to and including the 22nd. Extensive preparations are being made to adequately entertain the delegates and reduced fares have been secured on railways and steamships. Commander Giovanni Roncagli, secretary of the Italian Geological Society, is acting as general secretary of the Congress.

COMPENSATION of employees for damages due to accident should be required in all industries. At present, settlement is by individual suit, and the companies pay heavy toll to indemnity insurance companies. The result in that the money paid does not go to the ones needing it and is economically a waste. It is doubtful whether the cost would be much if any greater if the system were changed and the burden of accidents and death placed on each industry instead of on society as a whole.

FOREST FIRES are now under control, but the lesson taught by them should not be forgotten. A most excellent suggestion has been made by Mr. George M. Cornwall, editor of *The Timberman*, to the effect that considerable bodies of troops be encamped each year from April to October in the forests so as to secure adequate patrol of the territory in danger. It would afford excellent experience for the soldiers and would prevent the start of conflagrations. The force of forest rangers is none too large for regular work and in the dry season is pitifully inadequate. The forests were saved this year by the soldiers, but the work of prevention would be both easier and more effective than that of stopping fires once started.

ADMINISTRATION proposals in the direction of conservation were formulated in certain bills introduced at the last session of the Senate by Mr. Knute Nelson of Minnesota. These bills are extremely important as giving at least the tentative ideas of Mr. Taft and his advisers as to constructive work to be undertaken. But two of the administration bills have been passed, one separating surface

and mineral titles in the case of coal land, and the other defining the power of the President in the matter of withdrawing public land from entry. The remaining bills are pending. A useful work has been done by the Colorado Chapter of the American Mining Congress in preparing and circulating abstracts of these bills. Copies of the abstract may be obtained from Mr. A. W. Warwick, 1510 Court Place, Denver, Colorado. They should be read by all mining men particularly.

ARIZONA has elected delegates to a constitutional convention and the work of drafting the fundamental law of the new State will soon be begun. Mr. James Bryce, some years since noted a growing disposition to put into constitutions all manner of provisions previously left for statutory enactment. This tendency has become more and more marked as State after State has since joined the Union. The disadvantage of this plan is that it necessitates frequent changes in the constitution and in many ways leads to light treatment of what should be regarded most seriously. The opposite extreme may be noted in Illinois where some forty years ago the constitution was revised by men who were so well satisfied with their work that they made it all but impossible to secure adoption of amendments; a result that has seriously hampered the State and its chief city. Whether a constitution should be merely a bill of rights and subject to little change, or whether it should include a multitude of matters and be easily altered, thus coming to approximate the 'living constitution' of Great Britain, is a matter much debated. The action of the Arizona convention will be watched with interest. The land is one of large and varied resources and the people are representative progressive Americans. How they provide for the future will not only indicate the trend of present opinion, but will mean much for the whole country.

BRIEF reports on mining stocks and properties are often desired by those whose interest is too small to warrant payment of an engineer's fee for examination. It frequently happens that sufficient data already exist to warrant the sort of report demanded by the contingencies of the case. Relatively few purchasers of mining stocks know where to get such data or how to interpret them when available. The *Mining and Scientific Press* is often importuned to furnish such reports for its readers and others. We have consistently refused to do so, holding that such work is outside the province of a technical paper. We pay much attention to our news service and publish each week all of the information regarding mines that is available and that we consider important and reliable. A regular reader of our news columns can keep well informed about any district, but we cannot undertake to make reports on particular properties. This is the province of the engineer, and the best engineers are listed in our professional directory. Unfortunately, possibly, engineers have never developed a system corresponding to that of physicians, of small fees for office consultations. This would not be easy to do, since in the case of the physician the patient is himself before the doctor, while in the supposed case of the mining engineer, the property to be examined cannot well be brought to his office. None the less we believe something of this sort is capable of development to advantage. Brokers, it is true, furnish reports to prospective customers, and many such reports are accurate and adequate. While in many cases there is no reason to suspect the sincerity of the broker or the honesty of the report, brokers' statements do not answer the demand. The element of self interest is involved and naturally causes the inquirer, justly or unjustly, to discount the statements made. An attempt is being made by a new concern called the Mines Report Bureau, to meet the particular demand outlined. The many difficulties in the way are obvious but the need is real. Intelligent and honest effort should go far to assume success, and certainly editors of mining journals will wish the projectors well.

Illinois Coal Miners Strike

Settlement of the strike of the coal miners in Illinois is announced, the men having gained an almost complete victory. The compromise negotiated by Mr. T. L. Lewis and characterized by Mr. John Mitchell as a better agreement than any other labor leader had ever been able to win in the coalfield, was swept aside in the special convention of the miners and Mr. John Walker and the Illinois officials sent back to make their own settlement with the operators. There was talk of an attempt to introduce non-union labor and of testing the constitutionality of the law requiring certificated miners. This law, while nominally a measure of safety enforced by the State, is actually a bar to the introduction of strike breakers and effectually enforces the labor monopoly enjoyed in Illinois by the United Mine Workers of America. To operate with non-union men in the face of as universal unionism as prevails in the Illinois field would be impracticable and unprofitable in any event, and the plan was wisely abandoned. In the meantime the fall season was rapidly approaching and an actual coal famine was threatened. It was not in human nature for the men to surrender after having won their hard fight at Indianapolis and when a considerable number of the operators had already accepted the Peoria terms. Trade was slipping away from the Illinois operators and reluctantly they have conceded defeat. Mr. A. J. Moorshead and his associates have made a gallant fight and on the whole the members of the Coal Operators' Association have stood together with unusual unanimity. In a field such as that in the Middle West where there are such large areas of coal so cheaply opened and when the variation in seasons produces recurrent periods of large demand and feverish activity in mining, it is inevitable that the lean months be overlooked and more collieries opened than actual market demand justifies. Many a small mine must run, regardless of final profit, or be shut down by foreclosure. Anti-monopoly laws preclude any arti-

ficial regulation of production by agreement among the operators. The consequent weak position of the operators is the main strength of the men and they have played on it with rare ability. The cost of coal mining has steadily risen; it has been impossible for the producing companies to raise their selling price in like degree. Competition with the cheaper mined coal in the South is the most important factor. Non-union labor and a lower standard of living among the men in West Virginia and other competing States, together with an advantage in the average better quality of coal, permits the output of the collieries there to be sold to advantage in territory naturally belonging to Illinois operators. It is an open secret that there has been but little profit in coal mining in the Middle West in the last decade, and conditions are undeniably bad. What the final outcome will be can not be foretold, but apparently some form of legal combination must be found. The trouble is that this is more likely to be brought about, under present laws, in the interest of the railroads than otherwise. No independent group is at once sufficiently interested and sufficiently wealthy to carry it through, and a combination backed by the railways would naturally operate to still further increase the difference in the price per ton paid by them and by other purchasers. As it is, the profits in coal mining in this field come mainly from the small portion of the product used by householders and manufacturers.

Thou Shalt Not Steal

This solemn mandate was laid down many years ago and is as binding now as at any period in history. Whether we regard it as a Divine command or the crystallization of the highest ethical judgment of mankind, it is equally the only possible rule of conduct for self-respecting men. It is short; and neither in itself nor in the context, is there any mention of exceptions. It applies to gold ore as it does to horses: a fact that the West has been inclined to overlook. We have too long forgotten the fundamental character of the precept. In the curious topsy turvy code of the West it has been too common to hang horse thieves and joke about 'high-grading.' The statement that at Goldfield there are two grades of ore, "high-grade and company ore," carried to thoughtful men a sting and a reproach as well as a glint of light-hearted humor. Mr. Waldemar Lindgren startled the community by estimating at one time that a million dollars worth of high-grade ore had been stolen in one year, and informed managers believe that he did not overstate the case. We are glad to believe that at Goldfield, at least, stealing has since decreased. We judge this both from direct statement of managers and from indirect evidence. Single retail merchants no longer sell to a miner's wife in excess of the total amount of her husband's wages, as was once done. One merchant who recently retired and left the district stated that in 1906-1907 he made a profit of $250,000, and frankly admitted that probably the bulk of his profit went back to stolen ore. We would not, however, hold up Goldfield alone to condemnation, indeed we believe that stealing ore in the more important mines, at least, of that district has largely stopped. Grass Valley in California is one of the most charming of mining towns. The neat, white-painted, green-shuttered, miner's homes, surrounded by well kept gardens, with the blue sky, the yellow sunshine, and the background of green pines, afford one of the most attractive pictures in any American mining community. Here, the visitor would say, is mining at its best; a community of industrious, contented workmen and prosperous mines. In this same community, however, it is an open secret that ore stealing is constantly carried on. Despite specimen bosses and change rooms, the high-grade ore steadily finds its way out of the camp through illicit channels. Cripple Creek in Colorado has been cursed since its birth by thievery. Much of the disregard of law that has disgraced the community and that has especially characterized the labor troubles of the district, can be traced to the presence of men to whom ore stealing is a joke instead of a crime. Men who steal ore regularly are and have always been numerous in the mines. The old crowd of union men were driven out, but the non-union men who took their places are no more honest in this particular if in any. It is the common practice to lay all the blame of these conditions on the men, and in truth the major load must rest there. A thief is a thief the world over, and whether he steal a handful of rich ore each day or break into a safe at night, is not material. It is equally true, however, that a man who knowingly or willingly buys stolen ore, or the banker who handles bullion he has reason to believe comes from stolen ore, is as much a 'fence' as though he bought in silver plate for which the burglar has risked his life and liberty. No community persistently and continually harbors thieves of any kind, except public opinion tacitly condones the crime. The prevalence of 'high-grading' in mining districts indicates a low state of morals. It will not do to say that it is a phase of development in unsettled districts. Old mining communities as well as young suffer from it. Neither is it a peculiarly American crime. In Mexico, at Cobalt in Canada, at Kalgoorlie in Australia, on the Rand, in Siberia, indeed wherever rich ore tempts the miner, there are men who become thieves. They are criminals, and the community that tolerates them is no better, so far, than the outlaw camps of horse thieves that have been hunted off the plains. Under our present system of law and legal procedure it is all but impossible to secure conviction and punishment of 'high-graders.' There have been many proposals for change in the law to meet the case and in certain of the foreign districts unlawful possession of gold or silver is made a crime. Each man must account satisfactorily for any metal or rich ore found in his possession. This materially assists in protecting the mine owner, but this alone will not stop stealing. A better moral tone in mining communities is needed. There must be fewer euphomisms such as 'high-grader' and a sharp recognition of the fact that the man who steals ore is a thief.

Lessons From Gilpin County Practice

By George E. Collins

*Studies of mining practice in schools are apt to be drawn from cases which are prominent rather than typical. The great mines of the world attract disproportionate attention; their methods are more often described in technical articles, because the larger scale of working justifies and even necessitates a more elaborate organization, and because writers wish to identify themselves with successful undertakings.

Nevertheless, the great mines, or at all events the great districts, are unique as to ore-occurrence and economic conditions; and there is a disadvantage in directing attention exclusively to practice at the Calumet & Hecla or on the Rand, neglecting the host of small struggling mines and districts, which provide the problems with which most of you will have to grapple in your careers as mining engineers. It is a truism that there is more to be learned from our failures than from our successes. Accurate descriptions of milling methods, describing frankly why we put up with makeshifts, under the rigid but salutary pressure of economic conditions, or of mining practice, explaining why we do not adopt machinery or methods which might be preferable if the mine with which we have to deal would warrant them—these would be of greater value than elaborate descriptions of plants or methods which, for most mines, are out of the question. The young graduate from a technical school is particularly prone to indulge in a 'champagne' equipment for a 'beer' mine, because he has learned that it is the most 'modern' practice, and he wants to make a record for low costs.

Moreover, it is in this way that he can most easily gain credit for ability with the general public; for even the technical visitor, who, in the course of a short inspection, can readily appreciate a smoothly running equipment, is unable to grasp or cannot be informed of the inherent limitations of the mine or the financial considerations which render it necessary to strictly limit capital expenditure. It is not sound practice to make a saving of ten cents a ton, at the expense of a ten thousand dollar capital investment, if we have no assurrance of a sufficient tonnage to warrant it. It is mainly from this standpoint—the necessity of adapting means to ends—that I direct attention, for a short time, to some of the good, as well as the bad points, of methods in the district which lies almost at your own doors.

Gilpin county is a district of small mines and variable orebodies. It is true that the veins are persistent, but this is not true, as a rule, of the individual orebodies. The output for two generations has been remarkably steady, but when we come down to the individual mines, we find that few of them have been in operation continuously for more than eight or ten years at most. The largest producer today may be in borrasca or shut down altogether tomorrow. This is a basic condition of the district—not necessarily a result of want of foresight or bad methods. In soft veins, the expense of keeping open a great extent of levels and raises may easily counterbalance the advantage of maintaining a steady output. Recent technical writings have emphasized the fact that unworked ore reserves lock up a great deal of capital, the interest on which must ultimately be charged to the cost of extracting them. The characteristic ore occurrence in Gilpin county is a productive zone, usually of greater vertical than horizontal extension, in a fissure vein. In these zones the payable ore is not uniform, but tends to occur in disconnected or partly interrupted bonanzas. In most cases these zones were productive at the surface, and are intermittently productive to great depths. This condition, coupled with the laws in force at the time the mines were originally located, and the local topography, has naturally resulted in the opening of a great number of small mines close together, by means of independent shafts which, in many cases, have reached great depths, so that we have mines which are deeper than their length. At times they may be in bonanza, when they make a large production shipping to custom smelters and custom mills. At other times they turn poor, when they struggle along or shut down altogether, to be reopened later by some more hopeful or financially well-furnished person. Looking at the matter broadly, this is not an uneconomical method of working these mines. Its chief drawback is the expense attending the periodical reopening of the main working avenues, due to decay of timbers, fall of ground, and inflow of water. It is from this point of view that we see the economic justification for the long and expensive adits which are being driven to unwater and develop the Quartz Hill and Nevadaville districts. The total inflow of underground water is not great, as compared with that in such districts as Leadville or Cripple Creek. If we had to deal only with a few permanently worked mines, it would be possible to arrange for mutual drainage through one or two central pumping shafts. Unfortunately such is not the condition. Most of the properties are owned by people who have no intention of operating them, and the leasing individuals or associations who do much of the actual mining are indisposed or unable to plan very far ahead. In all my experience in Gilpin county, I recollect only one case in which a mine handling the water for its neighbors was able to induce (in this instance, to compel), any of them to contribute toward its water charges. The result has been that a few of the deep mines have always had to handle the water for an entire district. The expense involved in this has always been burdensome, but so long as they were in good ore, not overwhelmingly so. As soon, however, as each deep mine in succession became impoverished, the water charges caused its complete shut-down. Thus the water difficulty has become a successive inheritance, and the cost of unwatering the extensive old workings has been borne by various companies over and over again, so that together with

*Abstract from lectures delivered before Colorado School of Mines.

the constant expense of handling the regular incoming water, the aggregate cost has equalled a large percentage of the total output of the district. Therefore, in computing the benefit to be derived from a system of natural drainage, it is not enough to figure what would be the expense of holding the inflow by a single, well-equipped plant at a central shaft, but also to consider the greater indirect expense of periodically unwatering mines after a time of idleness, and the advantage of having every mine kept open, so that further exploration is not handicapped by the great expense of unwatering before a stroke of work can be done toward the opening of new ground.

The most characteristic method of handling mine water in Gilpin county has been that of bailing with water-buckets. Where a shaft can be purposely set aside for a sufficient part of the time, and where the hoisting equipment is already available, this is probably the cheapest method of handling water from considerable depths. In this case, the water being usually acid, variable in quantity with the season, and the tonnage of ore to be hoisted rarely equal to the capacity of the shaft and plant, it is a specially commendable method. It results in a wet and disagreeable condition in the shafts, but as this tends to preserve the shaft timbers from decay, it may be really a benefit.

I might illustrate the relative cheapness of bailing and steam pumps by referring to an actual case in 1895. At that time the Gold Coin Co. was working rich ground in the Indiana mine, west of the Hidden Treasure shaft, and handling the water by steam pumps. The California plant was practically idle, and a contract was taken to handle the water by bailing at one-half what it was costing to pump. Nearly half of this was profit. The other method most commonly adopted was that of pumping with steam pumps. The losses due to condensation in long lines of unprotected steam pipes, the dry-rotting of shaft timbers with the moist heat, the destruction of water columns by the warm acid water, the necessity of making provision for pumps of far greater capacity than was required for the regularly coming water in order to handle the spring inflow, combined to make this system particularly expensive under the local conditions.

The third method was the Cornish pump, which was installed at the Gunnell, Saratoga, and Monmouth-Kansas. In the first mine, it was destroyed by fire; in the second, unwisely replaced by a steam pump; and in all three cases the necessity for pumping has been or is being removed by drainage through the Argo tunnel. Nevertheless, the Cornish pump was eminently successful in Gilpin county, as elsewhere. The high relative cost of installation will doubtless militate against its further use in the district, except perhaps at some future time in the Briggs shaft of the Gregory vein, in connection with a comprehensive plan for the working of the Gregory-Bobtail group.

The final method to be considered is that which will probably be more and more generally adopted in future—the electrically-driven plunger pumps. Their freedom from most of the drawbacks of the steam pump, and, above all, the fact that they can be conveniently used to raise water to the level of the deep adits, will probably result in their general adoption to take care of the regular flow, supplemented by air-driven pumps or bailing in the spring months.

The 'Patch' and the Gilpin County Tramway.

The small and crooked shafts, following all the varying dips of the veins, have been much criticized, and every one who has tried to maintain a large output through one of them cannot but sympathize with the criticism. With the exception of the vertical Saratoga and Cook shafts, and the California shaft, inclined on the dip of the vein, I cannot recall a satisfactory deep shaft in the entire camp. But in this, as in so many other cases, 'to know all is to pardon all.' Gilpin County shafts mostly started out as prospect shafts, and followed the veins down. Probably, no doubt, they would have been better adapted for rapid hoisting had they been sunk parallel to the veins on the line of their average dip instead of in the veins themselves, and following every sinuosity. The trouble is that the dip of the veins is variable; some veins even completely reverse their dip more than once. Bearing in mind the legal condition—that most of the older and more important veins are covered by claims 50 ft. wide, and that the

right to the vein on its dip beyond the side lines depends on following it down from the apex—it is easy to understand why the shafts became crooked. For similar reasons the use of buckets instead of skips is general in the district. Nor is the bucket markedly inferior; except that, used without guides, it limits the hoisting speed. For small tonnages, and levels which do not extend far from the hoisting shaft, the Gilpin County plan of using two or three buckets and a trolley in the drift, unhooking the empty bucket and replacing it by the filled one, is one of the most economical methods of hoisting. For a large tonnage and longer trams, the use of low narrow cars, dumping by a tipple into pockets at the shaft, and filling from the shaft-pockets into a bucket, is similar to and nearly as economical as the best modern practice of loading into skips. The less satisfactory plan of using a cage was adopted at the Cook and Saratoga, but can hardly be regarded as a distinctively Gilpin County method.

Until about ten years ago, mining in the district was largely done either by tributing or on contract. We used to contract drifts, raises, winzes, and shafts at so much per linear foot, and stopes at so much per superficial square fathom. I doubt whether anything has done more to injure the prosperity of Gilpin County mining than the virtual abandonment of contract work, which has resulted in a marked decrease in the average efficiency of labor, and a corresponding increase in the cost of mining. There has been some advance in the standard daily wage, but this has not been equal to the increase in the cost of living, and has had relatively little influence on the increase of costs, compared with the lessened proportion of piece-work.

Contract prices for driving levels varied from $3 to $8 per linear foot; raises up to 100 ft. high about the same; in each case labor and materials for breaking ground, loading and tramming the broken dirt to the shaft, when not over three or four hundred feet distant, were included. Shaft sinking cost from $8 to $20 per foot including breaking ground, loading dirt, and setting shaft timbers. Stoping cost from $7 to $18 per square fathom of vein, and was mostly done on what is now called the 'shrinkage' system. Under this system, I believe, costs were as low as anywhere in the world under similar conditions. Needless to say, in contract stoping the closest supervision was necessary, to avoid either leaving large slabs of ore on the wall or breaking unnecessary waste with the ore. When high-grade smelting ore was found, necessitating special care in stripping and breaking down, the contract system was not applied, as the danger of losing ore became of greater importance than a small extra cost. When the entire vein was to be stripped and separately broken down, especially when adjacent to a soft 'shooting-course,' contract stoping was found to work well.

As a whole, the method requires more intelligent, if less constant, supervision than day's pay. It is probable that its abandonment was largely caused by the prejudice against it of bull-headed bosses and superintendents who disliked the worry it involves. Foremen, in particular, frequently oppose contracting because through it they lose the privilege of picking their men, and so favoring their friends, or in other and more innocent ways proclaiming their personal importance. Another thing which has tended to discredit the contract system is the shortsighted policy of some managers, who no sooner see contractors earning more than the standard wage of the district than they begin to cut the prices at which contracts are offered. This is a suicidal policy, for it disheartens the men, leads them to play foxy instead of using their utmost endeavors, and nullifies the essential object of the system—to provide an incentive for better work. Really, this policy usually arises out of ignorance. Such a manager does not know the value of the work, and looks only to the wage earned. The manager who cuts prices, directly high wages are earned, is doing as much to discredit the system as the unions who forbid their members to take contracts, unless guaranteed standard day's pay in any event.

The greatest benefit derived from piece-work is the improvement it effects in the quality of labor. Human nature being what it is, few men will continuously give the best that is in them without a special incentive. Why should a man work specially hard, or exercise his wits for the benefit of his employers, unless he reaps a direct reward for doing so? The day's pay system, which places all men of a class on one dead level as to pay, tends to reduce their work to a similar dead level; and as it is certain that the lazier or less skillful men can not or will not raise their standard of performance, it naturally results that the better men tend to reduce theirs to the level of the rest. It is useless to assert, as so many do, that a good foreman knows how much a competent miner should accomplish. His mental estimate is necessarily based on what the average man does accomplish, and while, in order to keep his men at all, he must make allowance for adverse accidental conditions, he cannot possibly know, from day to day, to what extent these have actually impeded each man's output.

Another method of securing good work is that of paying a little above the standard wage for the district. This may be effective, so long as one's neighbors do not adopt the same original idea. If they do, the remaining mines have to follow suit, or put up with the incompetent residuum. The final outcome is that we find we have succeeded in raising the general wage-level of the district, without making any change in the output of the men. The contract system, on the other hand, by holding out to every man a reward for working harder or using his brains more, and a penalty for laziness and stupidity, eventually raises the level of the labor efficiency of the entire district, although it may take several years for the improvement to become manifest. The day's pay system makes no provision for men and boys who are learning the business of mining. Under it they are compelled either to get their first jobs under false pretenses, pretending to be skilled miners when they are nothing of the kind, or to bribe some foreman. Under the contract system they can al-

ways get taken on to assist the more experienced miners, not as equal participants, but as learners.

The tributing system is especially applicable to the extraction of small, irregular patches of pay ground, to the final robbing of pillars in old stopes, prior to caving and abandonment, and to working of narrow rich ore streaks, where care in placing holes becomes more important than the quantity of work. Contrary to general belief, tributers do not often perform much real development work, unless encouraged by a 'footage' bonus or other special payment. Tributers do not usually work hard, and care should be taken to pay a 'footage' proportioned to the value of the work.

The maximum benefit of the tribute and contract systems is realized when pitches or contracts are taken by small parties of men, where every man realizes that he is dependent on his own exertions. We used to find that we could let driving contracts at a lower price per foot when we stipulated for one shift only, than when we required two or three shifts. In the former case, the men knew that if they did not make the progress they expected it was their own fault, and it was useless to blame it on the other shift. Similarly with tributing; I can see very little benefit in letting out large leases, as has been frequently done at Telluride and Cripple Creek. Where a lessee has to employ 50 or 60 miners, his lease is really an independent mine. It is not easy to see why the company's manager should not be able to employ equally good men, and use equally good judgment in following ore, as such a lessee, and the failure to do so would appear to be a reflection either on the capacity or the loyalty of the mine manager. On the other hand, when leasing to small parties of men, each of whom is vitally interested in the outcome, we are securing the brains of a whole host of men in place of one, and also their watchfulness of the ground and the ore to a degree that becomes a physical impossibility for any manager and his staff.

The greatest recent improvement in methods, tending to lower underground costs, is probably the adoption of the small hammer drill for stoping and raising. Except in the softest veins, such as the California, this has resulted in a cheapening of the expense of breaking ground in stopes. On the other hand, the dust produced is a difficulty which has still to be surmounted. For driving, the water feed to this type of machine has not been generally successful. I have seen a Waugh machine run with the air exhausting through hollow steel so as to discharge the cuttings, the resulting dust being so dense that I wonder any miner would work under conditions so dangerous to health. Except in cross-cuts or hard veins, driving can be done cheaper by single-jack than by machine. The work is, of course, slow, but this can usually be made up for by keeping a sufficient number of headings in progress. The levels can be carried narrower, and the smaller amount of explosive used shatters the walls less, so that the maintenance of hand-driven levels is less than that of levels driven by machine. As for double-hand drilling, where power is available, it is practically extinct; ground so hard that it cannot be economically drilled single-handed requires machine drills. The difficulty of breaking hard and tight ground has been lessened by the use of blasting gelatine, first regularly employed in the Roosevelt and Argo drainage tunnels. This is of relatively small importance in the soft Gilpin County veins.

The milling methods in use in Gilpin county have been subjected to even more drastic condemnation than the mining, with, on the whole, equally insufficient reason. By this I do not mean to be understood as claiming that the savings made on any given ore are the greatest economically possible. If it were practicable to design or adapt each mill to the particular type of ore it is to treat, much improvement could be realized. But here, as with the mining, the real crux of the problem is the nature of the ore-bodies. The ores even in the same vein vary so widely, physically and mineralogically, and the ore-bodies producing any given type of ore are usually so discontinuous, that by the time one has adapted his method to any particular ore it may have been exhausted, and one may have a very different ore to treat.

Hidden Treasure Mill, Gilpin County, Colorado.

The mills now in use are of three principal types: (1) The old-style, high-discharge, Gilpin County stamp-mill, in which battery amalgamation has been brought to a high degree of perfection, at the complete sacrifice of crushing efficiency. The reasons for the efficient amalgamation in the high-discharge stamp-mill have been convincingly indicated by T. A. Rickard in his 'Stamp Milling of Gold Ores,' and also by the late A. N. Rogers in a paper read twenty-five years ago before the American Institute of Mining Engineers. (2) The medium discharge, fast-drop stamp-mill, depending on outside plate amalgamation, the inferior amalgamating efficiency being compensated for by more effective concentration, due to the sulphide particles being less completely slimed. (3) The gradual reduction, straight concentration type of plant, in which standard wet concentration practice is adhered to as closely as the necessarily small size of the plant and other local conditions will permit.

Of these dissimilar types of mill, each will give commercially better results on certain classes of ore. Of neither can it be justly said that it is best suited for Gilpin County ores—or that it represents the

most 'modern' practice. I am inclined to think, as the result of my own experience, that the first-named type of mill gives the best commercial, if not the best technical, extraction, on the larger proportion of ores. I need hardly say that the mechanical features of the old high-discharge mills—the absence of crushers and mechanical feeders, etc., are excusable only because these appliances were unknown when the mills were built, and there is now insufficient fall to install them. This, however, does not affect the metallurgical features of the method. Gold recovered in the form of crude bullion by amalgamation sells to the mint for $20.67 per oz., and is subject only to nominal charges for refining. Gold recovered in sulphide concentrate, on the other hand, is paid for at the rate of only $19 per oz., and every ton of concentrate has to pay a minimum smelting rate of $3.50 and a minimum freight of 75c., so that it may frequently pay better to secure a smaller actual saving of gold, if a larger proportion be obtained in the more cheaply marketable form.

Speaking of the use of mill runs for testing, the old Gilpin County practice was to rely on mill runs throughout. One good reason for this was that the assay tells only half the story. Take for instance an ore assaying $5 per ton in gold. If $4 of this can be extracted in the form of retort bullion, it will usually be low-grade payable ore. If, on the other hand, only $1 is recoverable by amalgamation, and $3 more in the form of a fairly high-grade concentrate, it may be just on the boundary line. If, again, the ore yields $1 per ton by amalgamation, and concentration is in the ratio of three to one, yielding a product assaying $9, worth only $4.50 per ton net after deducting freight and smelting charges, then the commercial extraction, on the original ore, is only $2.50 per ton; and it is clearly unpayable.

The custom stamp-mills, with their small units of five stamps, lent themselves particularly well to this system, as a fairly complete clean-up can be made on very small quantities of ore. In Black Hawk today the millmen will accept and separately clean up lots as small as four tons; separate lots of eight tons are quite usual. In this way the mill-runs may be merely a large-scale sampling, but present the advantage of giving the commercial yield rather than the mere assay value.

The straight concentration mill does not lend itself to this system as well as the stamp-mill, because so much of the mineral is continuously tied up in jig and table beddings, and elevator sumps, and moreover, because the working unit is so much larger than the five-stamp battery, so that an accurate clean-up can hardly be made on lots of less than 30 to 50 tons.

Much of the criticism which has been popularly directed against Gilpin County milling is based on a superficial observation of the sulphide particles flowing off in the waste. That a considerable proportion of the sulphides—possibly one-third in the case of the high-discharge stamp-mills—fails to be saved by the concentrating appliances used, is true, but the fact does not necessarily justify condemnation of the milling practice or the concentrating tables used. You will often hear it said, by people who ought to know better, and would know better, if they took pains enough to investigate, that this loss of finely ground sulphides would be obviated by the use of 'modern' concentrating tables, such as Wilfleys, in place of the Gilpin County bumping-table. All this is beside the question; the bumping-table is just as valuable a machine as the Wilfley, and on fine unclassified pulp makes just as close a saving, although its range of utility is narrower.

Obviously it is possible to save a further percentage of these fine sulphide particles. The question is, how far will it pay to do so? The average assay value, in gold and silver, of the concentrate produced at one of the largest Black Hawk custom stamp-mills, for the last six years, has been a little below $9. Deducting smelting and freight charges, this is worth, net, $4.15 per ton. The concentration ratio averaged six to one, so that the net saving per ton of ore, in the form of concentrate, was 69c. If we could assume that one-third of the sulphide particles was lost, that 60% of this one-third could be saved by closer concentration, and that the selling value of a concentrate produced from the fine escaping particles would be equal to that of the concentrate actually saved, we should arrive at the conclusion that a further saving of 20.7c. per ton of original ore might be made, with a considerable capital investment and a small increase in milling costs. The gold in the sulphides is still in the metallic state, the finer division unlocks and exposes it to the action of the quicksilver, and consequently the fine particles are robbed of their contained gold to a greater extent than the coarse. So much for theory. It has been abundantly confirmed by practice. At the Hidden Treasure and Perigo mills, we used for years, bumping-screens to cut out the coarser sand over 60-mesh, and secondary bumping-tables and vanners, on the first bumping-table waste, and thereby saved a large additional bulk of concentrate. But these fine 'second concentrates' were invariably poorer in gold than the first—averaging more than 25% less in value. Still more important was the fact that the silica content could never be reduced sufficiently low to be salable on the same basis. It is generally known that fine sulphide concentrate can rarely be reduced below 20% insoluble without inordinate loss; and so we found it. The result was that a great deal of this second concentrate was commercially worthless, and the net saving only justified the extra expense when working on certain ores, such as those from which the gold in the heavy minerals was imperfectly extracted by amalgamation, or those which contained considerable silver.

I am hopeful of economic improvement in the milling practice of the district. In this connection, the cyanidation experiments recently made by Alsdorf, Draper, Gross, and Weed, afford considerable ground for encouragement. Of course, cyanidation experiments on Gilpin County ores and tailing are not new. A. L. Collins and I went into the question thoroughly, as we thought, ten or twelve years ago, and probably a host of other experimenters did the same. But finding the consumption of cyanide prohibitive,

in our attempts to cyanide concentrate, we confined our experiments to the treatment of tailing; and we reluctantly decided that the game was not worth the candle, especially as the saving by cyanidation appeared to be best on the ores on which fine grinding and amalgamation already gave the most satisfactory results, and as we made little progress with the silver-bearing ores, and also with those from the lower Russell Gulch district, in which tellurides occur intimately intermixed with the sulphide minerals. Alsdorf and his associates have shown that by treating fresh pulp without exposure to the air, pyritic mill tailing and even concentrate can be leached without undue consumption of cyanide. Mr. Gross informs me that in his latest experiments, he is able to extract 70% of the gold and 25% of the silver in concentrate by simple leaching, with a consumption of only 3 lb. of cyanide per ton of ore. Their experiments suggest that in the case of a large class of Gilpin County ores, the present commercial saving can be improved upon, not so much by increased extraction—for that is counterbalanced by the higher cost of treatment—as by getting the gold and silver into the more marketable form of cyanide precipitate and bullion, and so avoiding the heavy expense of freight and smelting on concentrate.

I am sometimes asked what is the average percentage of saving made in the Gilpin County stamp-mills. It is a difficult question to answer. The savings vary so greatly with the ores treated that no general statement can be of much value. When we speak of mill-savings in percentages, everything depends on the original value of the ore. A saving of 75% of the value of an ore assaying $4 is pretty good. The same percentage of saving on $20 ore is poor. What we have to consider is the actual assay value of the tailing, and whether it will cost more than the value recoverable to extract it.

During the cyanide experiments we made many years ago, we carefully sampled the entire flow of mill-tailing in the creek over a considerable period. Below the Hidden Treasure mill, the average tailing assayed, gold 0.045 oz., silver 0.80 oz. per ton. Above the Rocky Mountain concentrator the average tailing in the creek assayed, gold 0.065 oz., silver 1.00 oz. per ton. Figuring back with the aid of the records of bullion and concentrate saved at the former mill during the same period, it appears that the average saving, in bullion and concentrate, of everything that went into the mill, was about 75% of the gold and less than 40% of the silver. But the average grade of the ore was low, and we have repeatedly observed that, with better ore, the increase in assay of the tailing is by no means proportionate. I think I may safely estimate, on ore of average grade (say $5 to $10 in gold) a saving of 80% of the gold and 40% of the small silver value present, as characteristic of stamp-mill practice on the more amalgamable ores.

But there is a great deal of ore in the district, of an assay value of $5 to $10 in gold and silver, which is absolutely unpayable by any method or combination of methods now in use. I mean that it is large in the aggregate; I do not mean that the tonnage of such ore blocked out in any one mine is great. Part of this is sulphide ore, as in the lower Russell Gulch region, the gold value which is largely in the form of minute specks of telluride minerals. A considerable portion, notably that of the Kokomo-Searle-Adduddel vein, and many other veins producing similar ore around the fringes of the central district, is a complex sulphide ore containing almost as much silver as gold. The latter ores will often permit of a fair extraction of the gold by simple concentration. But the concentration ratio is low, and the silver saving invariably unsatisfactory. Above all, we are faced by the difficulty previously spoken of, the great variability and the relatively small size of the indivual ore deposits. Careful hand-sorting appears to be the only effective method of realizing profit from such ores, and unfortunately the high cost of labor is a great hindrance to sorting. The use of boys, of from 12 to 20 years of age, at wages suitable for such work, seems to me the most promising solution. Every old mining camp is at present full of young fellows who are through with school, unable to do the work and earn the wage of men, and are a nuisance to the community. To employ them as ore sorters would be valuable training for them in distinguishing ores, and would prepare them for better paid labor later on.

The so-called white oak timber of our markets is often a mixture not only of various species of the white oak group, but also of other species, such as the red oak. This generally unknown fact is reported by the U. S. Department of Agriculture, which, as a part of its forestry work, is frequently called upon to pass judgment upon the identity of market woods in dispute. At the present time it is almost impossible to obtain a consignment of white oak that does not contain pieces of some other species. Of the white-oak group those most used, in addition to the true white oak, are bur oak, chestnut oak, chinquapin oak, post oak, swamp white oak, cow oak, and overcup oak; of the black-oak group, Texas red oak, red oak, and spotted or water oak. Real white oak timber of No. 1 quality is very largely cut into quarter-sawed boards, while a combination of one or more white oaks and red oak may constitute other cuts of 'white oak.' In many markets, the term 'cabinet white oak' is now understood to include a mixture of white oak and red oak, while it often signifies red oak only.

The report of David F. Wilber, American Consul at Kobe, Japan, states that shipments of sulphur from that Japanese port increased largely during 1909. This sulphur is the product of volcanic springs on the island of Kyushu, and when simply congealed, in which condition it is sacked and shipped, the result is 99.8% pure sulphur. Exports to the United States can hardly be expected to increase very much, as this product has been held subject to the duty on refined sulphur. On the other hand, sulphur mined in the Hokkaido in a solid state and subjected to a process of melting in large boilers and then sorted into several grades is admitted to the United States free of duty.

The Eastern Canadian Mineral Belt

By Theo. F. Van Wagenen

The success that has attended the development of the silver-bearing lodes of Cobalt, coupled with the prosperity of the copper-nickel mining industry that has been established for many years at Sudbury, makes it clear that eastern Canada has a mineral belt of great importance, and will justify some general remarks about the region between the Great Lakes and Hudson's Bay; a part of the continent which, until a few years ago, was considered as of small account except for its forests and fur-bearing animals. Geographically there are few parts of North America less intimately known to the general public. This is not the place for an extended account of the rise of the Dominion as a nation, but it will not be amiss as a preface to some statements as to the Hudson's Bay country, to give an outline of the history and topography of British North America, which has now become completely organized politically, and whose progress commercially is really of more importance to Americans than that of any other part of the world outside of our own land.

Eastern Canada.

It is altogether likely that the fine old Norwegian viking, Bjarni Herjulfson, who was cruising off the southwest coast of Greenland in the year 986, and who reported having sighted land toward the west, was the first white man to see the shores of Canada as represented by the forbidding and rugged coast of Labrador on this side of Davis Strait. Four years later his countryman, Leif Ericson, sailed for a thousand miles or more down that inhospitable shore, trying to find a harbor and some signs of human habitation. Both these bold explorers left such hazy and indefinite accounts of their discoveries that it has been impossible to identify the exact position of the lands they saw. Nor did their stories apparently make much impression at home, for nearly five hundred years passed before the next European, the Englishman John Cabot, appeared in the same region. He, however, had the good fortune to slip in between the bold headlands of Newfoundland and Cape Breton, and discovered the great bay of the St. Lawrence; and claiming it all for his country, together with everything in the shape of land and water around or near it, as was the cheerful custom of the explorers of the day, laid the foundation for the British claim for the possession of that part of the new world. In 1504 French fishermen began to frequent the Newfoundland banks, and during the years 1506-8 the estuary of the St. Lawrence was thoroughly explored by them, and its coasts well mapped; thus laying a still broader foundation for the claims of France to the same region. In 1535-6 Jacques Cartier ascended the great new river as far as the present site of Montreal, and during the succeeding years of the century the southern part of the country now known as the province of Quebec was dotted with settlements of his countrymen. In 1603 occurred the first voyage of that old sea-dog Champlain, who pushed his explorations westward to the shores of Lakes Ontario and Huron, and southward into what is now the State of New York, giving his name to the long and lovely lake lying between it and Vermont. It was during this period of daring discovery that the French came into intimate relations with the natives of the St. Lawrence valley, and espousing the cause of the northern tribes (comprehended mainly under the names of the Hurons and Algonquins) against a more southerly combination known as the 'Five Nations,' headed by the Iroquois, who later were backed up by the English, brought on the Indian wars that, with occasional intermission, continued until the close of the century.

In 1610 Hudson's Bay was discovered by the Englishman who gave it name, and shortly thereafter began the long war between the British and the French for the possession of the St. Lawrence valley and the upper Mississippi country, which continued, with occasional intermissions depending mainly upon the political conditions and changes in Europe, for fully 150 years. During the period perhaps the greatest sufferers were the natives, over whose lands the fierce contest raged, and who were involved, sometimes much against their will, but generally without difficulty through mutual jealousies skillfully played upon by the invading white man. During the long conflict some of the tribes were practically annihilated, and all were so broken and depleted at its end as to be no longer formidable. In 1625 the French Jesuits began to arrive. These fine pioneers spread rapidly throughout the Lake region and became also the first explorers of the vast and wonderful wilderness between them and the Pacific ocean, where their names appear often in the appellation of rivers, lakes, and settlements.

In 1670, the Hudson's Bay company was formed, ostensibly for purely commercial purposes, but actually to give England a sea base to the north of the St. Lawrence valley from which the attack against France could be pressed, as well as from the south. The bitter struggles of the years from 1682 to 1713 ensued, at the end of which France abandoned all claims to what was then called the 'Hudson's Bay' region, and the great English company was given a chance to expand. This it did so effectually that by

1750 its posts had reached the shores of the Arctic at the mouth of the Mackenzie river, and of the Pacific at the entrances to the Columbia and Frazer, including all the vast territory between, and confining the French to the lower St. Lawrenee valley. In 1763, pressed as she was on all sides, France gave up the unequal struggle, and resigned her Canadian sovereignty to England, yet securing for her children in the new world full recognition of their individual rights by treaty provisions that have been so scrupulously observed by England that today there are no more loyal subjects of the British crown than the French Canadians. In 1783 England, in her turn, resigned to the United States—which meantime had won its independence—that portion of the territory originally claimed by the French which now composes the States of Ohio, Indiana, Illinois, Michigan, and Wiseonsin. In 1846, the forty-ninth parallel of latitude was agreed upon as the southern border of western Canada, thus adding Minnesota, the Dakotas, Montana, Idaho, Washington, and Oregon to the domain of the Republic. During many following years Canada was almost forgotten by the outside world. The only thickly settled portions were, the southern parts of what are now the provinees of Ontario and Quebec, all the balance being practically abandoned to the Hudson's Bay company. By 1850, however, the upper Mississippi States were filling so rapidly with settlers, and the discovery of gold on the Pacifie coast was drawing such a horde of miners and farmers and explorers into the Northwest, that it became evident that much of the border land to the north of the forty-ninth parallel was of value, and steps were taken toward the political organization of the then almost unknown Canadian Northwest. In 1859, the monopoly of the Hudson's Bay company was confined to the unsettled regions immediately around the Bay and the valley of the Mackenzie river, and in 1867 the Dominion of Canada was organized politieally, in whieh were united under one government all the British eolonies and possessions remaining in North America except Newfoundland. Two years later the great fur company accepted the new sovereignty. This final step paved the way for the remarkable growth and progress which our neighbor to the north has been enjoying during the last ten or twelve years, and which, from now on, may be expected to be continuous.

Topographically, a bird's-eye view of the vast stretch of continent to the north of us displays the following main features. First, the continuation northward along the west coast, with a width of three to five hundred miles, and without a break from the Washington boundary to that of Alaska, of the rugged series of parallel mountain ranges that are known as the Rocky Mountains. From this vast uplift, composed mainly of sedimentary rocks, the country slopes away eastward in broad plains toward Hudson's Bay, for many hundred miles. The western parts of these plains are treeless and semiarid, like our own, though erossed at frequent intervals by rivers of size and importance. Second, traversing these plains in a general east and west direetion, are two almost imperceptible divides, one of which throws the waters of the Maekenzie, the Coppermine, and the Great Fish rivers northward to the Arctic, while the other drives the drainage of the Missouri and Mississippi southward to the Gulf of Mexico. Two forks of the latter, curving respectively to the north and the south of Lake Superior, and then extending eastward again, confines the waters that reach the ocean through the Great Lakes and the St. Lawrence.

The Canadian plains are underlain with sedimentaries like our own, but they fall away rather more rapidly than with us, and when within four to five hundred miles of Hudson's Bay they begin to rise, forming a basin with its longer axis bearing north and south. Finally, the beds terminate on an ascending floor of Archean granites, gneisses, and schists whieh, after gaining altitudes of 1000 to 1500 ft., continues as a plateau for fifty or one hundred miles more and then sinks away rapidly to sea-level all around the great Bay. This extensive exposure of primitive rock, which is the third great topographical feature of the Dominion, is called the Laurentian Plateau. It completely surrounds the southern end of Hudson's Bay, and extends up each side toward the north like the arms of a gigantic letter U, passing under the sedimentaries, as stated, to the westward, but on the eastern side extending clear aeross what used to be known as Labrador, but which is now called the province of Ungava, to the shores of the Atlantic, where it constitutes a bold and rugged coast line that in places rises to heights of over 6000 ft. To the southward this remarkable area of ancient rocks extends into northern Minnesota, Wisconsin, and Michigan, completely encircling Lake Superior, and then passes under later formations. It is this old geological continent, which covers practically all of the provinces of Keewatin, Quebec, Ungava, and Labrador, and nearly all of Ontario except the peninsula between Lakes Huron, Erie, and Ontario, which is beginning to be recognized as a mineral field of unique characteristics and possibilities. What is known of it to date is expressed in the wonderful iron deposits in northern Minnesota, Wisconsin, and Michigan, which occupy points along its southern edge, the copper districts of the Keweenaw peninsula, the copper-nickel field at Sudbury, and the silver-cobalt-niekel lodes of the Cobalt district. From any point of view it is one of the most remarkable regions, mineralogically, at present known. It is but a short time, geologically speaking, since the great ice sheet of the last glacial epoch disappeared from its surface, leaving it dotted with millions of big and little lakes connected by streams that are in places navigable by canoe, but which are broken at many points by rapids so that frequent portages are neeessary. If it was ever covered wholly or in part by rocks of later date, they have been completely scored away. What is left is a tremendous area of the original crust of the earth, thinly covered here and there with the remains of the very first of the beds that were laid down on the floor of earth's oldest ocean. What may not be expected in the way of mineralogieal and geological surprises from such a region! Though the soil is shallow, a dense forest

of spruce, pine, hemlock, tamarack, and birch covers much of the land. There are no well defined mountains, but in their place an unending succession of low ridges, running to all points of the compass and enclosing depressions that are invariably filled with water. The maximum depths and heights are from two to three hundred feet. In making the frequent portages that are necessary the traveler is impressed with the abundant occurrence of dikes of ancient eruptives. The surface is fairly damascened with them. All the rocks are of a dark and sombre color, and in chemical composition are probably basic. Everywhere the effects of strain and distortion such as would be expected to occur throughout a semi-plastic mass, are visible, being particularly apparent in the banded rocks. Little surface decomposition has taken place, and experience in mining is to the effect that the lodes are tight and carry little water. The ore deposits to be expected therefore will belong mainly to the primary class, consisting of the metals of high specific gravity, rarely oxidized, often intimately associated, and usually in the form of sulphides or in the native condition. It is a region where the prospector and miner will find himself somewhat nearer to the unknown and mysterious interior of the globe than is usual, and will be confronted with many of the rarer minerals. Gold is widely distributed, but at only a few places has it yet been found sufficiently concentrated to be profitable. It is certain also that several of the metals of the platinum group have been detected, and for these the formations are particularly friendly. Important deposits of the radio-active elements may also be anticipated.

The most accessible new portion of this interesting region is along the line of the Temiskaming & Northern Ontario railway, a government built and operated concern that begins at the town of North Bay on Lake Nipissing and is heading for Hudson's Bay. It passes through the town of Cobalt, which has many of the well known characteristics of an American mining camp. The road is about 270 miles in length, and terminates (for the present) at a little town called Cochrane. Here the surveyed line of the Grand Trunk Pacific railroad (also a government institution) is intersected, and grading and track-laying upon it are in progress in both directions. This new trans-continental line begins nominally at Quebec, and will run in a direction a little north of west, directly across the Laurentian Plateau, passing a few miles to the north of Lake Abitibi, and thence, approximately along the fiftieth parallel, to Winnipeg. It will be a couple of years at least before it will be open for traffic. Meantime Cochrane is being made an attractive supply and outfitting town, from which, as a centre, it is hoped that the prospector may be induced to explore the surrounding country, for the officials of the Dominion government are well aware of the promising nature of the region. What success will be attained by this rather paternal way of drawing population and opening the country remains yet to be seen, and depends much upon the miner's opinion of the Canadian mining law. It is the popular impression that the country is covered with prospectors at the present time, for reports of new finds are continually coming in. In the course of a week's travel in one of the most attractive parts I failed to meet a single one, but did meet several 'claim peggers.' There is a broad distinction between the two.

It is not a difficult country to prospect, nor yet an easy one. From June 1 until September I the climate is often disagreeably warm during the day, though the nights are invariably cold. The ground is clear of snow, the lakes and rivers of ice, and canoe travel delightful. One keeps moving from lake to lake across portages ranging from a quarter of a mile to a mile in length, and two hardy men with a light boat and kit can cover a big area during a season. The mosquitoes and black flies are bad for a few weeks of this period, but head veils and rubber gloves, and a bottle of oil of citronella will keep them at bay during the day, while at night it is easy to sling a net over the bed. Rains are frequent and uncomfortable during July, and between the showers the air is muggy and oppressive, and so much of the country is covered by lakes and swamps that travel on horseback is out of the question. On the other hand, there are no mountains to speak of, and the bedrock comes to the surface all around the lakes and on the summits of all the ridges as well as over much of their slopes. Thus the veins are easy to find and trace. Fish and game are abundant, and in the towns along the railroad or near them, all necessary supplies may be purchased at reasonable prices. The few natives that are left are segregated on reservations, and are entirely friendly. The only large animal that might be dangerous is the black bear, and he will always make off if given a fair chance. The woods are full of blueberries and raspberries. The spring and fall months are uncomfortable, for summer is coming and going, and weather occurs that fools the unwary, and makes much trouble. During the winter the snow accumulates to depths of six to twelve feet, the mercury sinks to forty and even sixty below zero, and prospecting is impossible. The residents, however, consider the winter the finest of the seasons, for traveling on the snow and ice is easy and expeditious, the winds are light, and the game is at its best.

The coal beds of South Park, Colorado, occur in what is presumably the Laramie formation, consisting of sandstone with subordinate beds of carbonaceous shale and ranging in thickness from knife-blade seams to 375 ft. No fossils have been found in the formation but it rests on a yellow sandstone containing upper Montana marine fossils and is unconformably overlain by conglomerate beds that are undoubtedly equivalent to part, at least, of the Shoshone group, as typically developed in the Denver basin.

There are no fixed rules of design as relating to gas-engine bearings, construction usually following the results of experience. In the leading makes the diameters of the main and crank-pin bearings approximate 35% of the bore of the cylinder: the piston-pin bearing approximates 25 per cent.

Smelter Fume in Shasta County, California

By Sumner S. Smith

With the closing of the plant of the First National Copper Co., at Coram, by the farmers' association of the district, and the suspension of the Bully Hill, at Winthrop, on account of a Government suit, the smelter fume question in Shasta county, California, has recently reached an acute stage, and with copper between 12 and 13 cents per pound, and curtailment facing the large producers, there is little in-

Balaklala Smelter at Coram.

ducement for the smelting companies to expend large sums in additional equipment. Last spring the farmers formed the Shasta County Farmers' Protective Association and a compromise was effected with the Mammoth and First National companies whereby the solid particles should be removed from the smoke and the SO_2 diluted before the fume passed into the air. To attempt to relieve the situation by the erection of acid plants is at present out of the question as the estimated production of H_2SO_4 by the smelters of the county is 1200 tons 60°B. per day; the market, aside from that supplied, being about 40

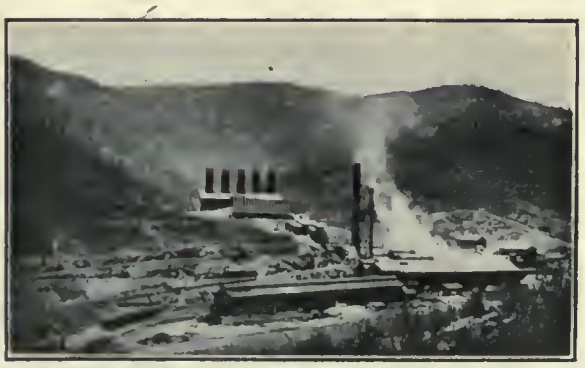
Bag-House at Mammoth Plant, Kennett.

tons. The compromise was based on the decision of Judge J. A. Marshall, in the Utah Federal Court, who held that the SO_3 uniting with the moisture in the air to form H_2SO_4 was the main cause of damage, the SO_2 having but slight effect. There are at present three copper smelters in Shasta, the Keswick plant of the Mountain Copper Co. having been practically dismantled. The ones remaining are the Mammoth plant of the United States Smelting, Refining & Mining Co. at Kennett which includes five blast-furnaces having a capacity of over 2000 tons of charge per day, the ore in which contains 40% sulphur; the Balaklala, or First National Copper Co.'s plant at Coram, which contains four McDougall and three blast-furnaces with an operating capacity of 1400 tons of charge; and the Bully Hill plant of the General Electric company which handles approximately 600 tons of charge per day. The ore from the Balaklala mine contains approximately 34% sulphur and the Bully Hill 20% sulphur with considerable zinc.

The Mammoth company through its parent, the

Balaklala Tram, Mine Terminal.

United States Smelting, Mining & Refining Co. having gone through a similar experience in Utah, had plans ready for a bag-house, since built, which contains 1000 long woolen bags to filter the smoke. Experiments were tried with both cotton and woolen cloth, the wool, though higher in first cost, proving



Balaklala Smelter, General View.

to be the more effective and lasting longer. The gases from the furnace pass through a large chamber where they are mixed with cool air, and through intercooling tubes to the bag-house proper which is divided into five compartments any one of which can be shut down for the removal of the dust. The

Balaklala Tram, Smelter Terminal.

bags are attached to a mechanical shaker, the jar from which loosens the dust so it falls into hoppers, from which it is drawn into cars. It is then dumped into a mixing puddle, sprayed with water, and briquetted, the bricks then being returned to the blast-furnace.

The First National company was not so fortunate in the matter of ready plans and had to spend considerable time in experimenting before finally adopt-

ing the Cottrell process as being the least expensive both as to first cost and upkeep. The former dust-chamber was tapped and nine Cottrell units set in parallel to convey the smoke to the new dust-chamber, from which the fume, free from dust and SO_3, is drawn by fans that mix it with cool air, thus lowering the percentage of SO_2 in the gas that escapes from the stack. The Cottrell units consist of steel chambers 10 by 10 feet square with hopper bottoms from which the dust is removed by a screw conveyor. Inside the chambers are a series of positively charged bars made of two strands of asbestos and two copper wires set between a series of iron plates which are grounded. In passing through the apparatus the smoke is forced against the high-potential, asbestos-covered, bars, the solid particles receiving a positive charge which precipitates them on the low-potential iron bars. The complete plant is under control of the operator in the power-house and any of the units may be shut down at any time for cleaning. This process consists of jarring the plates slightly to shake the dust into the hoppers. A lateral conveyor serves all the units taking the dust to a briquetting machine from which it will be returned to the blast-furnace.

Owing to the time spent in experimenting and constructing the new machinery, the First National company could not complete the plant on the stipulated date, July 1, so asked the privilege of running one furnace at half capacity for the purpose of holding the force together, and having the smoke to experiment with while constructing. It was also desired to treat a small amount of Bully Hill ore as the company had a contract for such work. However, the farmers, like men intoxicated with a new-found power, voted 60 against 2 in favor of closing the plant. This, with the shut-down at Bully Hill on account of the Government, the reduced capacity at the Mammoth, and the closing of a number of independent low-grade quartz mines that can only be operated when their product is sold to the smelters for flux, threw out of employment between 1200 and 1500 men and greatly endangered the industry from which the county derives its principal revenue. The assessed valuation of these smelters, exclusive of the mines, at 60% of their real value is $1,757,463. They employ over 2400 men and distribute a payroll of approximately $200,000 per month.

Important smelting operations began in Shasta county about 1897, and since that time the assessed valuation of the county has sprung from about $7,000,000 to over $16,000,000, three-fourths of this increase being directly due to increased activity in the copper belt. With the revenue derived from the taxes paid by the companies mining and smelting copper ore, Shasta county has enjoyed an era of marked prosperity. New communities have sprung up and the older towns have become prosperous business centres. The county is free from debt and without increasing the tax rate or issuing bonds has purchased toll roads and built new highways, constructed steel and concrete bridges, erected a county hospital, a hall of records, and a high school, employing at the latter a staff of instructors that would otherwise be absolutely impossible. In the area in question the merchants derive considerably over 90% of their support from those connected with the mining and smelting industries. Outside the tract near Keswick less than 5000 acres are affected seriously while 10,000 acres show slight though tangible evidence of damage. Within the Shasta National Forest, which the Government claimed was injured by the Bully Hill plant, two sections showed slight damage and one of these was railroad land. The timber is the poorest grade of 'bull' pine and scrub oak, being useful only for mine timbers and firewood. That close enough to the smelter to suffer from the fumes was practically all cut before the smoke had a chance to seriously affect it. Within less than three miles of this plant both vegetables and fruit trees flourish although for a long time the most destructive practice, that of roasting in open heaps, was maintained. Three years ago when the General Electric Co. took over the property it built a standard-gauge railroad from Pitt, on the Southern Pacific, to the smelter at Winthrop, and completely remodeled the plant, erecting a high stack in order to allow the gases ample opportunity for diffusion.

The effect of the smoke near the plants is cumulative, especially on evergreens, such as the pines, but is largely overcome by cultivation and irrigation. The farms in the Anderson district, while opposing the smelters the strongest, produced record crops last year when a greater volume of smoke was thrown into the air than at any other period in the history of smelting in the county. A certain damage is wrought on both grain and garden truck, but the local market for these furnished by those engaged in the copper has far more than compensated for the losses. It is, however, easier to lay the blame for failure of crops on the smoke than to investigate the deterioration of the soil or various blights, and the companies' pocket-books have been quite accessible as every effort to avoid law-suits has been made. While the spirit of those who have been the leaders in the movement against the smelting companies has been one of fairness and compromise, the majority with short-sighted policy have believed in obtaining 'all the traffic would bear' demanding their 'pound of flesh' even at the risk of killing the business that has supplied over 90% of the trade to the merchants of the district and brought the county from comparative obscurity to one of the leaders of the State.

After exploring the eastern coast of Kamchatka for two years, the Prozorov expedition has returned to St. Petersburg. Mr. Prozorov, who is the president of the St. Petersburg Stock Exchange, obtained a concession in Kamchatka extending from Baron Korff bay to the Kamchatka river, amounting to some nine million acres, and sent out an expedition under an engineer named Natsvalov to explore it. In the vicinity of Baron Korff bay some beds of good coal were found, but the net result of the expedition was to show that there are no mineral resources of importance in eastern Kamchatka. Only traces of placer gold, of copper, and of sulphur were found by the expedition.

Filter-Pressing Slimes

By M. W. von Bernewitz

*The filter-press, which has done so much for the successful treatment of the sulpho-telluride ores of Kalgoorlie, Australia, has a rival in the vacuum process; and this paper is written with a view to arousing more interest in the cheaper working of the press, it being doubtful whether its efficieney in extraction can be improved.

At the Associated Northern Blocks, where these notes were compiled, the average value of the ore of late has been $6.48 per ton. It is dry crushed in three No. 5 Krupp mills. The crushed ore is roasted in six Merton ordinary type furnaces. This is ground in eight 5-ft. grinding pans with weak KCN solution. The slime from the pans is thickened, run into vats, and agitated in the usual way. The three presses are of the Dehne type, with 50 frames 39 by 39 by 3 in., and 50 plates for the filter-cloth, and the angle lever screwing-up gear. Each press holds 4.75 tons of dry slime. Filling is done by a Pearn 3-throw pump running at 20 r.p.m., with plungers 12 by 10 in., taking about 15 minutes to fill a press at 60 lb. pressure, that is, if the slime is fairly thick. In filling there appears to be a settlement of the heavier slime particles toward the bottom of the cake.

In the centre of nearly every cake of slime is a thin seam of fine sand, due to the solution, during filling, going out on either side. It is a curious thing, and possibly has some influence on subsequent washing. Nothing is gained by filling presses at high pressure. Sixty pounds has been found right for speed in filling and economy in power. A pump similar to that used for filling, but running at 13 r.p.m., is used for washing the presses. Experiment has demonstrated that 75 lb. is the right pressure for good and cheap washing. At 120 lb., 5.2 tons of wash is pumped through in a half hour, and at 75 lb., 4 tons, this giving less than one ton of wash per ton of slime. This varies with the way the press has been charged. In washing, the solution enters the high pressure plate, passes through the cloth, then through the 3-in. cake, and finally into the low-pressure plate and out.

The drop in value is fast from the start to after 10 minutes, then decreases slowly. The sump solution assayed a trace of gold and tested 0.06% KCN. During filling the vat charge was only 0.036%. With the low-grade ore treated most of the gold was dissolved in the pans and an agitation of only four hours was necessary with 0.036% KCN. This was run from the presses to the zinc-boxes, but was made up with strong solution before passing them, thus giving 0.06% sump solution, when the agitator charge was only 0.036.

Mention was made of the settlement of slime particles during filling. Careful sampling gave an average residue of 30c. per ton from the top, centre, and bottom of the cake, the sand parting being the same; at the same time, it would seem that the coarser material would let more wash through to the detriment of the finer portion of the cake. This is true in very sandy slime. A water wash of 5 min. after 25 min. KCN wash is of little benefit, and tests show that it takes 20 min. for the water to thoroughly displace the cyanide. Blowing or aerating a press charge after filling and washing is of no benefit.

As to the amount of soluble gold left in the residue, samples washed for some time with water showed 20c. per ton less than that discharged. It will not pay to go on washing until the soluble gold is all out, and it is doubtful whether it could be washed out. With high-grade ore, or when the roast is poor, the difference is much greater. With a residue assaying $1.92 per ton the washed samples would be 72c., and on a 96c. residue, about 48c. per ton. This shows the faulty washing (or something else), that goes on at times in the press. Washing presses from the high or low-pressure plates gave no difference, only keeping the cloths a trifle softer. Changing all the cloths regularly has been done with fair results in better washing, but did not pay. One trouble was that the cakes would not dry properly for some days, this being bad for discharging to belts. Cloths here last from 6 to 8 weeks. Hessian was tried under the cloths for some time to save them from cutting, but the advantage was not equal to the expense. Corrugations on the plates, especially the high pressure, get full of lime compounds, which interfere with the free flow of the wash. It is fairly soft and is scraped out, but on the low-pressure plates the deposit crystallizes very hard. Assays of this have given as high as $24 per ton.

In six years at this plant only one frame was broken, but an average of two plates are broken monthy, the number of high and low-pressure plates being equal. The breakages may be due to shock from the filling pump, such as a sudden rush of pulp; or one channel in a frame may be choked and all the pressure be on one side; or from turning on the wash too suddenly, or at too high a pressure. A blocked channel is the most usual cause. Plates cost from $16.80 to $24. The Oroya-Links makes its own plates, which are good and cost $14.40 each. Martin's foundry, in South Australia, made a plate, the inside part being separate from the outside or frame part, so that there could be no breakage in the usual place. If one plunger of the filling pump is not working, the pressure rises and falls a good deal, and several breakages were due to this cause. To catch the leakage from a press 20-gauge galvanized corrugated iron is used, these lasting for two years or more. After washing, the press is dried, for two minutes, with air at 90 lb. pressure, each using 2640 cu. ft. of free air. The residue contains 22% moisture, and although this is high, it is cheaper to lose a little weak and barren solution than to use expensive air.

Two men dump 11 presses in 8 hours, being paid 64c. per press, having to keep them properly clothed, greased, and cleaned. The cycle of operations takes up the following time: filling, 15; washing, 30; drying, 2; dumping, 30; total, 77 minutes. During 1909, 44,163 tons was treated for an average extraction of

*Abstract from Proc. Aust. Inst. Min. Eng.

93%, and costing for agitating and cyaniding 31c., and for filter-pressing 25c. per ton. The present cost of disposal of residue is 10c. per ton.

Over 60,000 tons of residue was re-treated. The system consisted in trucking to the belt-conveyor, elevating to a mixer, mixing with sump solution, and running into an agitator, although no agitation was necessary, this acting really as a storage vat; filling the press and washing 10 minutes. On the last 12 months' re-treatment of 24,675 tons the average was 78% extraction at a cost of 78c., of which re-mixing cost 44c.; pressing, 24c.; and disposition of residue, 10 cents.

Some of this was hard to get at, hence the re-mixing cost (trucking, elevating, and mixing) is high. The cyanide consumption never exceeded 3 lb. per ton of residue. The vacuum plant may be cheaper in first cost than the press plant; but its efficiency is no higher, although costs are a little lower on old dumps. Some method of emptying the filter-press without having to open it is much desired, as it would do away with some of the cost of discharging, and part of the cost of disposing of the residue, and the press would only have to be opened for the renewal of cloths. Sluicing is the only method possible, and unless cheap water can be procured, this would not pay. Experimenting on this line, one end of the charging channel was left open, and the wash valve either to the high or low-pressure plates, or both, was also left open. Pumping water for half an hour at from 75 to 120 lb. pressure, from 4 to 6 tons was used and the best test showed only one-third of the slime washed out. A great deal depends on the state of the cloths; as it seems that, as soon as the water makes a channel in many cakes it simply runs away and does no further washing. These methods are too slow and expensive in power and water.

Mr. James, recently of the Golden Links, has a small press of local design fitted with a device of local invention for sluicing and had success in sluicing out cakes of oxidized-ore slime. The frames are cast with a slot near one corner of the bottom fitted with a narrow door with rubber joint, worked by a lever and cam. A 4-in. pipe runs the length of the press with a bend and nozzle for each frame. When the press has been washed the doors are opened and the pipe lifted up by an easy method, the nozzles pointing up into each frame. Water at 50-lb. pressure is used and the pipe slowly turned through an arc of 90°, the slime coming out through the doors into a launder. About 2 of water to 1 of slime would be sufficient to wash out the porous slime in the presses of Kalgoorlie. To install this system would mean fitting or casting new frames with discharge slots. The other thing necessary is water at 36c. per 1000 gal.† Some more work on these lines would be a great value to the cheaper working of the filter-press, and it is to be hoped that somebody will follow up this subject.

†This may need some explanation for American mining men. Under the new arrangement with the W. A. Government, the mines on the Golden Mile get water for ordinary purposes at $1.68 per 1000 gal., and for sluicing away residue, at 36c. per 1000 gal., but there is doubt whether we would be allowed to use this cheap water in the presses.

GOLDFIELD CONSOLIDATED REPORT

The following data are from the August report of the Goldfield Consolidated Mines Company.

TONNAGE PRODUCED

	Wet Tons.	Dry Tons.	Av. oz. per ton.
Combination	4,875	4,641	1.50
Mohawk	8,313	7,913	1.29
Red Top	4,022	3,929	2.06
Clermont	8,077	7,687	2.31
Total	25,287	24,170	1.78

The performance of the mill was as follows:

Dry tons milled	24,170
Average value per ton	$36.82
Total value	$889,968
Loss in tailing	$58,455
Value realized	$831,515
Percentage extracted	93.43

EXPENSES

	Amount.	Average per Ton.
General:		
Bullion tax and marketing bullion	$ 16,000	
Administration, etc	16,000	
	$ 32,000	$1.32
Mining	80,000	3.31
Transportation	3,300	0.14
Milling:		
Milling and cyaniding $58,200		
Marketing concentrate residues 9,600	67,800	2.81
Construction	25,000	1.03
Net cost	$208,100	8.61
Loss in tailing	58,453	2.42
Total costs and losses	$266,653	11.03
Profit per ton		$25.79
Total value of ore		$36.82
Total profit for month		$623,415
Percentage of profit		70.05

For the first time since March the mine produced approximately full tonnage. This might have been reached in July except for some shortage of water. There is no reason to expect any shortage in future. The mine looks well. The total advance in exploration work was 3297 feet.

The showing of the Combination was particularly good, resulting in the opening of the Hampton orebody at the bottom level of that mine. At the Mohawk mine the developments continue with fair success between the Mohawk proper and the Red Top. One stope particularly, on the 350-ft. level, near the Mohawk shaft, has been very promising. At the Laguna shaft a small orebody of rather low grade has been opened. The level now being opened in this mine is 230 ft. vertically below the bottom level of the Red Top, so that any ore opened will indicate a considerable tonnage. At the Clermont no ore of consequence was discovered during the month. Some promising showings have been met recently, but it is too early to report on them definitely. Construction is progressing satisfactorily at both mine and mill. The entire plant is in good condition. The completion of work now on hand will, in the course of two months, substitute some economies for the expense of construction.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Palmarejo & Mexican Mining Company.

The Editor:

Sir—In your paper of July 23, under the head of Special Correspondence, are remarks pertaining to the Palmarejo property to which I take exception. Your correspondent said "several men of position made attempts to improve the methods of mining and metallurgy. It was found that the orebodies were irregular and the content low, averaging 2 dwt. gold and 15 oz. silver. The ore was of too low grade for amalgamation and would not give good results by any cyanide process known at that time."

I took the management of this property March, 1901. At that time the system of milling was dry-crushing, roasting, and pan-amalgamation. Learning that this system was very unsuccessful we at once started with a series of experiments and finally decided on a system of wet-crushing, concentrating, and cyaniding. This system was described in the Trans. Amer. Inst. Min. Eng., in a paper read at the Washington meeting, May, 1905, and also published in your paper. To save space I do not care to go into details as to the results of our operations. I would like, however, to refer you to some statements which were made at the seventh ordinary general meeting of the shareholders three years later, and to the action of the shareholders at an extraordinary general meeting convened on May 30, 1905. Much comment was made at this meeting: I would ask, in justice to my work and reputation, that you print Baron Boxall's statement, who was at that time one of the large shareholders of the company, also that of Mr. Perry, who is at present the president of the company. These statements, I think, will convince any person that the changes made by me at that time were successful, and whatever modern and up to date method that may be recommended now by E. T. McCarthy, cannot reflect on our work of five and ten years ago.

Baron Boxall: "In seconding the resolution which has been put so clearly from the chair, I should like to emphasize one subject which has been alluded to. Thomas Henry Oxnam accepted this company's retainer at a time when it was in distress, if not in commercial disgrace. He designed the remodelment of the company's operations, and in so doing made certain estimates, estimates of returns which the facts and figures disclosed to you have proved to have been understated (hear, hear) and he drew scientific conclusions as the result of his practical experience which have proved to be absolutely correct. (Applause.) It is now three years since he accepted your retainer. During that time I do not suppose there have been many hours during which your interests have been out of his thoughts. His work as the chairman has just stated, and that of the staff, has raised this company from a state of impecuniosity to one of opulence, and, more than that, by demonstrating that with an establishment of not more than fifty stamps we can operate under the present conditions at a profit on the basis of between £40,000 and £50,000 per annum; he endowed your mining interests with a capital value which it is not for me to assess. When I first spoke to Mr. Oxnam on the subject of this business, noticing that he seemed a little hesitating about the magnitude of the work before him, I took upon myself to tell him that in my judgment he was not working for a class of persons that would, after the event, either allow honorable and sound service to be corrupted in any manner or to pass into oblivion; and as an Englishman, speaking to you as Englishmen, I do not suppose for a moment that any of you would fall into such a serious error. Remarks concerning him are bound up in the resolution which is before the meeting today, approving of the report shortly after the declaration of the first dividend, but I should like a message to go forth from this meeting this afternoon that we particularly wish him to come here in the spring, when we can, in his presence, pursue the subject further (hear, hear) and at the some time deal with another matter which has been under the consideration of various shareholders during the past few weeks, upon which they are provisionally resolved, and which I know have only to be mentioned to you to receive your hearty support and endorsement. I beg to second the resolution confirming the report and balance-sheet." (Applause.)

Mr. John Perry said that he was very glad to be able to endorse all that Baron Boxall had said in reference to the general manager. He (the speaker) had been engaged in mining practically all his life, and, so far as he knew, he never came across a better man. (Hear, hear.) If the shareholders compared the report with that of last year, they would see what has been done, and no doubt, they would fully appreciate the value of the general manager's services. (Hear, hear.) The motion was then put and carried unanimously. Mr. Goddard proposed a vote of thanks to T. H. Oxnam, the general manager, to the milling and mining superintendents, to the accountants, and to the heads of the different departments. He had the greatest satisfaction and confidence in proposing this vote of thanks, because he was sure the shareholders generally would recognize the skillful and judicious manner in which Mr. Oxnam and his colleagues had so far developed and were still developing their great property. (Applause.)

At an extraordinary general meeting of the shareholders of the Palmarejo & Mexican Gold Fields, Ltd., convened on the 30th day of May, 1905, to receive Mr. Thomas Henry Oxnam, of Los Angeles, the company's consulting engineer on his visit to London, it was proposed by Baron Boxall, seconded by Mr. Ehrlich, and resolved unanimously: That the thanks of the members of the company be tendered to Mr. Oxnam, for his valued and exceptional personal services to the company, 1901 to 1905, and as a special mark of appreciation the company

hereby votes him a bonus or grant of fifteen hundred guineas, to be paid to him irrespective of all other remuneration and in pursuance of a resolution of the directors to that effect. And it is further requested by the meeting: That a copy of the minute of this resolution be signed by the directors, and handed to Mr. Oxnam previous to his return to Los Angeles. Signed:

Thomas Southcott, chairman; E. J. Duval, Jno. Perry, Geo. Hallett, directors; Percy F. Gaunt, secretary.

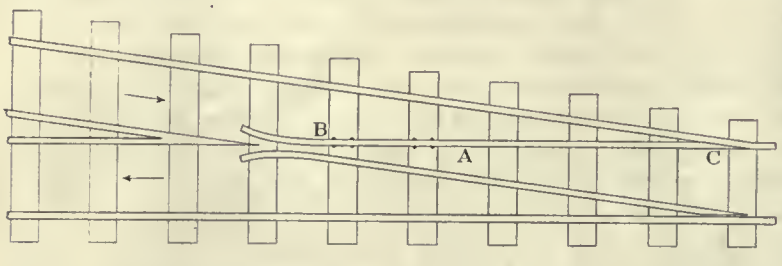
T. H. Oxnam.

Doble, Victorville, California, August 15.

The Spring Switch

The Editor:

Sir—I have read the description of the spring switch by S. S. Clarke, in your issue of August 20, and appreciate the ingenuity displayed in its construction. I have used a spring switch which will operate fully as well as that described by Mr. Clarke and which can be more simply and less expensively made. It operates by utilizing the elasticity of the rails themselves instead of employing an extraneous spring of any kind to readjust the switch points to position after the passage of the car or train. I have had such a switch as I here refer to built on a single-track tramway where a turn-out was necessary. It was arranged as shown in the accompanying sketch; designed so that cars could pass in either direction without stopping to throw the switch, thereby accomplishing all that the hickory-spring switch performs, with less trouble, and little likelihood of getting out of order. The switch is constructed as shown, the spring rail A being on the outgoing track, and extending from the frog to the rail as shown by B C. Only one rail is arranged to spring. This rail should be as long as possible, at least 12 ft., and if spiked too close to the point C, it may be too stiff to spring easily and in that case would probably derail a car. Where this switch is placed at a turn-out, as in the case mentioned, it is best to keep the outgoing line straight, as over this track the loaded cars pass, while the empties return on the outside curved track. In places where, for lack of room, a length of rail cannot be employed which will admit of the necessary amount of spring, the hickory spring will afford the desired means of automatically operating the switch. At the opposite end of the turn-out the spring rail would, as a matter of course, be placed on the opposite side of the main line, the outgoing loaded cars springing the switch point.



Superintendent.

Placerville, California, September 1.

A Cyanide Problem

The Editor:

Sir—In reply to Mine Owner's inquiry for a process for the treatment of auriferous and argentiferous ores containing antimony, it appears to me that the difficulty should not be insurmountable, always provided, of course, that the ore will stand the treatment charges. J. S. McArthur proposes a pretty process, consisting of dissolving the antimony—that is, when the antimony occurs as sulphide—by first leaching the ore with a solution of caustic potash, precipitating the antimony from the solution as sulphide by passing carbonic acid gas, and then revivifying the solution, ready for use again, with caustic lime. If there is no other deleterious content, the ore—now free from antimony—may be treated with cyanide in the usual way. This process is not applicable to ores in which the antimony occurs as metal. Antimony may be removed from an ore by roasting if a reducing agent such as coke dust be added from time to time during the process. During the roast, antimony sulphide or metal is converted into Sb_2O_3 and Sb_2O_5, which are volatile, and Sb_2O_4, which is fixed; the function of the reducing agent is to reduce any Sb_2O_4 that may be formed and would otherwise remain with the ore, to Sb_2O_3, which, being volatile, will pass away up the flues. An article of mine, that appeared in *Mining and Scientific Press* April 28, 1906, and was reproduced in T. A. Rickard's 'After Earthquake and Fire,' gave the results of a number of experiments, which may interest Mine Owner.

F. H. Mason.

San Diego, California, September 7.

No assessment work is required in Russia, and owing to that fact large mining claims may be held indefinitely without working, on the payment of a small annual tax. This has been regarded by many observers as one of the greatest obstacles to mining progress there. It has enabled many local merchants and small capitalists to play the dog in the manger and hold large numbers of unproved mining claims on the chance of a mining boom that will enable them to sell out at high prices. In this way hundreds of thousands of acres of promising ground is tied up. To meet this condition a clause was inserted in the last mining code providing for a supplementary tax on mining claims that were not being worked. This provision, however, raised a storm of protest, and the Duma, in accordance with the recommendation of the Minister of Commerce and Industry, has suspended the operation of this law until 1913. The representatives of the miners pointed out that gold mining was in a critical position and that any additional tax or restriction would injure it severely.

Concrete and reinforced concrete poles are now used for high-tension transmission lines, it being no unusual occurrence to carry lines with a difference of potential of 70,000 volts.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Reheating compressed air is often found to be a great advantage especially where the air has to travel a long distance to the point of consumption. A convenient method is to use a boiler for an air receiver, keeping a fire going in the fire-box.

Dynamite should never be stored in underground workings longer than absolutely necessary and then in places especially prepared to keep it dry. It is customary in the larger mines to bring fresh supplies daily to the underground distributing stations.

The temperature of concrete in setting is to be determined at the Gatun locks by embedding thermometers in the concrete when it is poured. The thermometers will be of the resistance type, in which measurements are taken of the resistance of a wire to an electric current, and the temperature thus determined.

Bottles and glass jars may be cut off easily and cleanly with the tools found in any tin shop. First solder a strip of tin around the bottle at the line where it is desired to cut it. Then run the soldering iron around the bottle parallel to the tin strip. The bottom, or top, as the case may be, can then be easily broken off.

All spring bars, especially if they be of small cross-section, should be annealed before being shipped from the rolling mill. This is done by bringing them up to a full cherry-red heat in the furnace, 800°C., and allowing them to cool slowly after being maintained at this temperature for a sufficient time to allow of uniform heating.

The rating of air-compressors when expressed in the number of rock-drills to which they are capable of supplying air should not be made at a pressure of less than 80 lb. per sq. in. With a 3-in. drill this will approximate 130 cu. ft. of free air per minute though if a number of drills are being used it will be proportionately less as all the drills are not in operation at the same time.

A coal-dust burner using a jet of compressed air instead of a fan blast has been in successful operation for the past two years in a southern cement factory. Air at high pressure passes through a Koerting ejector nozzle and enters the kiln through a horizontal pipe. A vertical fuel supply pipe opens into the horizontal pipe just beyond the discharge end of the nozzle, and between the nozzle and the kiln, the rapidly moving air-jet carrying the coal dust into the furnace.

Of the 5,000,000 hp. theoretically available at Niagara Falls only 270,000 hp. or 5.4% has thus far been utilized. Of this 126,000 hp. is employed in electro-chemical processes, 56,000 hp. for railway service, 36,400 hp. for lighting, and 45,500 hp. for various industrial services. Nearly 125,000 hp. is transmitted to points more than ten miles from the falls. Of this amount 12,300 hp. is transmitted over a distance of more than 100 miles, while 33,500 hp. is transmitted between 75 and 100 miles.

Lead and mercury in the mercurous condition are precipitated from solution by the addition of HCl. The $PbCl_2$ is dissolved by hot water and confirmed by the addition of H_2S, H_2SO_4, K_2CrO_4, or KI. The mercury is identified by addition of $NH_4(OH)$ which turns the precipitate black. Mercury in the mercuric condition is precipitated by passing hydrosulphuric acid in the warm solution and is separated from the other metals of the second group by the non-solubility of the sulphide in $(NH_4)_2S_x$ and in dilute HNO_3. The sulphide is dissolved in nitrohydrochloric acid and the presence of mercury confirmed by the precipitation of Hg on a copper wire or the reduction to HgCl or Hg by $SnCl_2$.

Iron-portland cement is a hydraulic compound which consists of at least 70% portland cement clinker and, at the best, 30% granulated blast-furnace slag. The portland cement is prepared according to the definition of the German standard specifications for portland cement. The furnace slags are lime-alumina-silicates. They contain at least 1 part by weight of lime and magnesia to 1 part by weight of soluble silica (SiO_2) + alumina (Al_2O_3). The portland cement and the slag must be ground finely. Additions for particular purposes, especially for regulating the time of setting, are admissible, limiting the amount, however, to 3% of the whole mass, in order to exclude the possibility of additions only for increasing the weight.

The flow over triangular weirs has been the subject of extended investigation by James Barr at Glasgow University. The investigations were undertaken in order to verify the formula $Q = cH^{5/2}$, proposed by James Thomson for the flow of water over a right-angled or V-shaped notch, and also to determine experimentally the values of the coefficient c in that formula. Mr. Barr says in *Engineering*, London, that the results verify Mr. Thomson's anticipation that the quantity is in almost all cases nearly proportional to the 5/2 power of the height of the still water surface above the vertex of the notch. The results also show that the prevention of the inward flow of the water at the sides of the notch, whether caused by the narrowness of the notch or by the roughness of the upstream surface produces an increase in the quantity over the notch. Experiments on a right-angled weir of very fine edge show that for heads of approximately 3 in. the coefficient c is about 0.3034; for heads of about 4 in. the coefficient is about 0.3020; for heads of 5 in., about 0.3014. For a notch in which the sides make an angle of 54°, thus giving an area of orifice half that of the right-angled notch, the coefficients for the different heads are slightly greater than half those for the right-angled notch. It is stated that the experiments were made with the aid of very delicate apparatus.

Special Correspondence

WASHINGTON, D. C.

J. A. Holmes, Director of Mining Bureau. — Report on Explosibility of Coal Dust.

Official Washington, which had all along been taking a keen interest in the candidacy of Joseph A. Holmes for director of the newly created Bureau of Mines, heard with great satisfaction that he had been appointed. A few hours after the news became public, both the President and Mr. Holmes were overwhelmed with telegrams of congratulations. Mr. Holmes took the oath of office on September 10. The temporary director, George Otis Smith, also Director of the Geological Survey, will return from Europe October 1. That Mr. Holmes is qualified by past experience is evident. He graduated at Cornell University in 1880. During his college course and since that time he has devoted special attention to studies in chemistry (with laboratory courses in the chemistry of explosives and of metallurgy), geology, electricity, and general physics, surveying, mining, and metallurgy. He has visited mining regions in many parts of the United States, in Germany, France, Belgium, and Great Britain. In these foreign countries as well as in the United States he has studied the methods of mining with special reference to lessening the loss of life and waste of resources. He was professor of geology in the University of North Carolina for ten years and in that capacity visited many mines in the professional way. As State Geologist for North Carolina for two years he gave much attention to an investigation of quarrying, metal mining, and metallurgical operations. In 1903 and 1904 he organized and had charge of the Department of Mines and Metallurgy of the World's Fair at St. Louis, planning the exhibits to show mining and metallurgical operations. In 1904, when the Government fuel investigations were authorized by Congress, the supervision was placed under a committee consisting of E. W. Parker, M. R. Campbell, and Mr. Holmes. Early in 1905, the latter was appointed by the Director of the Geological Survey to take charge of the investigations of fuel and of mine explosions, etc. When the Technologic branch of the United States Geological Survey was formed, he was placed at the head. In 1908, Congress appropriated $150,000 for a thorough investigation of the causes of mine disasters and this was added to his duties. In connection with his work during the last three years, Mr. Holmes has won the confidence and co-operation of both miners and mine owners throughout the country. Notwithstanding the fact that the work has only just begun, results of the investigations and educational work are beginning to appear in lessening the loss of life in the coal mines. In 1907, 3125 men were killed in the coal mines; in 1908, this had been reduced to 2450; in 1909, the deaths numbered 2412. In 1907, 145,471 tons of coal were mined for each life lost; in 1908, 167,545 tons were mined for each death; and in 1909, 186,567 tons were mined for each life lost.

The Bureau of Mines has just issued a bulletin on the explosibility of coal dust, with chapters by J. C. W. Frazer, Axel Larsen, Frank Haas, and Carl Scholz. The bulletin was prepared by the Technologic branch of the United States Geological Survey, and therefore will be known as Geological Survey Bulletin 425, but will be distributed by the Bureau of Mines. The author of the bulletin, George S. Rice, chief mining engineer of the Bureau, goes fully into one of the most serious and most perplexing problems that the coal mines have had to contend with in the last few years. He traces the growth in the belief in the explosibility of coal dust, summarizes the experiments and mine investigations that have established this belief and gives the present status of preventive measures. The following are some of the tentative conclusions of Mr. Rice: "That coal dust will explode under some circumstances, both in the presence of firedamp and without it, is now generally accepted by mining men. Experiments at Pittsburg indicate that under ordinary conditions the dust must be from coal having at least 10% of volatile combustible matter, though in certain foreign experiments, it is claimed, explosions were obtained with charcoal dust. Dusts with higher percentages of volatile combustible matter are more sensitive, ash, moisture content, and size being constant. This view is based partly on the preliminary experiments at Pittsburg and on the results of experiments of M. Taffanel and other foreign investigators. Where there is a large amount of dry coal dust, judging from the Pittsburg experiments, a humid atmosphere has little effect on ignition of dust or propagation of an explosion. A long continuance of the humid conditions renders the coal dust moist and inert, but the presence of moisture in the air at the moment of explosion is not sufficient to prevent an explosion; that is, not enough moisture is carried by the mine air to reduce materially the temperature of the flame. Fully saturated vapor at 65°F., an ordinary mine temperature in this country, weighs 6.78 grains per cubic foot (15.5 grams per cubic metre). Coal dust suspended in such a saturated atmosphere in a cloud of moderate density weighs, say, 200 grams per cubic metre. At the figures given the weight of vapor is but 7.8% of the weight of dust. The Pittsburg experiments with wetted dust showed that several times this percentage of moisture in the dust, in addition to a nearly saturated atmosphere, was required to prevent propagation. Probably with a low dust density, the relative humidity of the air would be an important factor in tending to prevent the initiation of an explosion. However, the great purpose of artificially humidifying mine air is that it may serve as a vehicle for carrying water to the dust." Mr. Rice concludes by reviewing the various remedies that are offered for the coal-dust problem, giving the good and bad points of each.

ANACONDA, MONTANA

Georgetown District.—Cable Mine. — Southern Cross. — Orofino.

Cable, Georgetown, and Southern Cross camps are all within two miles of each other, situated in a mountainous region twenty miles westerly from Anaconda, Deer Lodge county, Montana. In this vicinity is a chain of small lakes, the outlet of which flows toward Philipsburg. It is a gold mining district, where operations began in 1865, the gold-bearing ore occurring as pockets, shoots, and chimneys in limestone. The Cable mine, one of the oldest in the camp, is said to have a record of having produced $4,000,000 in free gold. The property is now owned by the Cable Lease Mining Co., in which H. C. and F. W. Bacorn, and associates, are in control. The property includes a 30-stamp mill, not now in operation, air-compressors, and all necessary equipment. A small force is employed on development and exploration work, mostly above the main adit which goes in 3000 ft. Within the last few years a great deal of diamond-drill work has been done as a means of exploring in new ground. The result is said to be that some good orebodies have been found, though they occur as pockets rather than continuous bodies. A 300-ft. winze, sunk from the principal adit, has resulted in opening some sulphide ore, including a little tellurium. Some tests are being made on the mill tailing with the view of cyaniding it.

The Southern Cross mine and mill are one and a half miles northwest from Cable, on the opposite side of a mountain divide. This property belongs principally to the H. L. Frank estate, though Lee Mantle and others have a considerable interest. As demonstrated by the development work, there are three principal north-south veins, about 150 ft. apart, within a zone of limestone. Those veins are known as the Southern Cross, Intermediate, and Trinity; besides, there is a well-defined chimney of ore on the group, known as the Pleades. The veins have a dip of 55°, and have widths varying from 20 to 100 ft. The ore runs approximately 12% silica, 55 to 65 oxide of iron, and 20 to 30 lime; and is claimed to average over $10 gold per ton. It contains some silver, amounting to less than $1 per ton. It is seldom that bodies of ore are found that are so thoroughly oxidized as these seem to be to a depth of over 300 ft. The mine is opened to a depth of 326 ft. by a

vertical shaft, levels from which extend to the Southern Cross, Intermediate, and Trinity veins, and into the Pleades. The greatest amount of development appears to be on the Intermediate. On the third level of this vein there appears a body of ore 75 to 100 ft. wide, from which it is said 200 cars of ore were shipped to the Anaconda smelter within the last two years. The big stope, on the fourth level of this vein, is 60 to 100 ft. wide, and 500 ft. long. It is stated the net value of this ore was $17.60 per ton. Similar ore is found on the other two veins, but much less in width. A 130-ft. winze, following the dip of the Southern Cross vein, extends in ore from the 200 to the 300-ft. level. The Pleades chimney is 50 to 60 ft. diameter, and is detached from the other orebodies. It has been opened from the surface to a depth of 300 ft. on the dip. It contains a good grade of ore. Since January 1, 1909, 175 cars of ore have been shipped from the mine to the smelter, the proceeds having been expended for development. In making these shipments the better grade was selected, resulting in an average of $28.50 per ton. One carload, for which the highest grade was selected, had a gross value of $250 per ton. It should be stated that a number of large boulders of lime and shale occur within the veins and contain no metals of value. An unusual occurrence is a small lens of copper carbonate and copper glance on the second level, which sampled 10% copper, but no similar ore has been found in the other parts of the mine. The plan is to sink deeper and establish two more levels. A mill, equipped with a crusher, rolls, Chilean mill, cyanide vats, and Moore filters, was erected four years ago, but after being started it was closed at the end of four months, and has since been idle. Present plans, however, contemplate the resumption of mill work. John Randall, of Denver, is on the ground making investigations with that object in view. It is estimated that there are 30,000 tons of ore on the dump, running $10 to $12 per ton, which may be treated. The operations are under the general direction of O. T. H. Allen, whose son is in charge of the underground work.

The Orofino mine, situated close to the Southern Cross, is being operated by Charles Bostrom, who owns a half interest and has a lease on the other half. The orebody here is in the form of a good-sized chimney in limestone, the apex of the orebody outcropping. It has been opened by a 300-ft. incline which follows the ore on its dip; also, by a 155-ft. vertical shaft, designed to be the main working shaft. A stope above the 100-ft. level has been carried 10 sets high, and 25 to 30 ft. wide, the ore from which was shipped to the smelter. The main body of the ore-shoot seems surrounded by a rim of harder and lower-grade ore next to the limestone walls. Considerable work has been done from a lower level, showing similar conditions. The intention is to sink deeper, and it is probable that an electric hoist and an air-compressor will be installed this fall. The ore contains 26 to 33% silica, and 45 to 60 iron, with some lime and quartz. The iron is thoroughly oxidized. According to the returns from 20 cars of ore shipped to the Washoe smelter during August, the ore netted the shipper about $35 per ton. Out of this, however, comes the wagon-haul charge of $3 per ton. Since June 15 Mr. Bostrom has shipped 45 cars, and is now shipping a car every other day. In pursuing development and exploration a second ore-shoot or chimney has been found about 200 ft. from the one from which ore is being shipped. F. R. Jackson and J. N. Durbin have taken a lease on the Pyrannes tailing dump at Georgtown, which they are treating by cyanide. The Revenue, situated between Georgetown and Cable, is under lease to H. C. Ernst and M. Benson, who expect to ship ore this fall. Other lessees are making occasional shipments. The smelter pays 5c. per unit for the iron in the Cable district ores, which in some cases amounts to nearly enough to pay the treatment charge.

CHICAGO, ILLINOIS

Meeting of Lake Superior Institute.—New Officers.

Two hundred and thirty-three members of the Lake Superior Mining Institute, celebrating the fifteenth annual meeting, reached Chicago by way of Milwaukee, August 25, at 11:30 a. m. Two special trains carrying the delegates were switched into the freight yards of the Sullivan Machinery Co., where the tour of inspection began. Here light refreshments were served, and after a visit through the plant automobiles were taken, through the courtesy of that company, for the trip over the West Park boulevards through Garfield and Douglas parks to the Ryerson plant, arriving at 1 p. m., where J. T. Ryerson & Son were hosts at an elegant luncheon followed by a tour of inspection of the plant. This 'iron and steel department store' is the largest in the world for the storage of machine and structural steel and specialties needed in the mining branches of steel construction and manufacture. It covers 750,000 sq. ft. of floor space and affords storage for 150,000 tons of material. Automobiles were then taken to the National League ball park, where the Cubs were seen in a contest with New York. After the game automobiles were taken to the train and the party left for Gary, Indiana, arriving at 8 p. m. The members pursued their way to Assembly Hall, where the second business session of the Institute occurred. The meeting was called to order with D. E. Sutherland in the chair. R. B. Woodworth read by title a paper on 'Underground Steel Construction, Particularly Mine Shafts,' and discussed the instability of wood as a material of construction and the evidence that steel is the most homogeneous material known. Charles S. Hurter then read by title a paper on 'The Proper Detonation of High Explosives,' and discussed from a mechanical and chemical standpoint the action of the explosives used today. The difference between high and low explosives was explained and the merits of Chile and India niter as a dope was compared. Mr. Hurter said that heat increased the sensitiveness of explosives and that when accidents occur it was generally due to increased sensitiveness caused by heat. He explained that shock and heat often combine to cause detonation, that if a drop of hot candle grease falling on a cap caused detonation it was due as much to the shock

Lake Superior Institute of Mining Engineers in Chicago.

as to the heat, and that a capsule of copper had such a high heat conductivity that it made little difference whether the drop of hot grease fell on the fulminate or the capsule. Considerable discussion followed on the methods of packing detonators in boxes for shipment. The following papers were presented: 'Mining Methods on the Gogebic Range,' by P. S. Williams; 'The Mine Doctor', by E. M. Libby; 'Reminiscences of the Early Days on the Gogebic Range,' by Jon H. Herding; 'A Diamond-Drill Cross-Section of the Mesabi Rocks,' by N. H. Winchell, 'A Steel Head-Frame,' by Frank B. Goodman; 'The Newport Mine,' by Luther C. Brewer; 'Biographical Sketches,' by John H. Herding. Titles of other papers are to be presented later. The report of the council followed. Forty-six applications for membership were received, making a total membership of 553. A. J. Yungbluth, the secretary, stated that the fiscal year closed with $5000 in the treasury. F. W. Sperr then reported for the committee on nominations, and the following were unanimously elected: For president, W. J. Richards, Crystal Falls, Michigan; vice-presidents, E. D. Bryan, Chicago, Illinois, C. H. Munger, Duluth, Minnesota; managers, Peter Pascoe, Republic, Michigan, J. R. Cooper, Lake Linden, Michigan; treasurer, E. W. Hopkins, Commonwealth, Wisconsin; secretary, A. J. Yungbluth, Ishpeming, Michigan. On Friday, at 9 a. m., the party started on a tour of inspection of the Gary works of the U. S. Steel Corporation, the plant site of which covers 900 acres. They first visited the harbor slip which is 250 ft. wide and 5000 long. Vessels laden with 12,000 tons of ore are unloaded at the rate of 1250 tons per hour. Running parallel to the vessel slip and in line with eight blast-furnaces nearby, is a storage yard with a capacity of four million tons. After inspecting the blast-furnaces the party was led to the gas-engine buildings, where sixteen 2000-hp. gas engines operate the blast-furnaces and seventeen 3000-hp. gas engines drive electric generators. The gas for these engines is supplied from the blast-furnaces as by-product gas. Next came the open-hearth furnace rooms containing 65 open-heart furnaces. It is estimated that the Gary works will give employment to 12,000 men. In addition there have been reserved plant sites for the American Sheet & Tin Plate Co., the American Bridge Co., the National Tube Co., the American Car & Foundry Co., and the American Locomotive Co. In the afternoon the party returned to Chicago and at 6:30 attended a banquet in the gold room in the Congress Hotel annex at which the E. I. du Pont de Nemours Powder Co. acted as hosts.

MELBOURNE, AUSTRALIA

State Coal Mine.—Mt. Maroomba Boom.—Mt. Morgan.

The Victorian Government is pushing ahead with its experimental State coal mine at Powlett. The Railway Department is the great consumer for the coal and it is intended, when the mine is properly equipped, to hand it over to the Railway Department to run. The Minister of Mines wishes to be able to supply coal to the community at cost price regardless of profit. At present the whole public supply is obtained from the Newcastle field in New South Wales, and the average price of the coal delivered to the householder is about 25s. per ton. To the manufacturer or large consumer the cost is probably about 20s. per ton, and to the Railway Commissioners about 18s. per ton. The expectation is that the Railway Commissioners will be able to get Powlett coal for something like 15s. per ton. The Newcastle mines can supply at that price or even lower, but to do so would mean that the selling price, which has been raised by the combine controlling the industry there and by the Newcastle Miners' Association, will have to come down and with it the wages of the miner. It is not clear how labor is to benefit by any reduction in the price of Victorian coal, although unquestionably the householder will get vastly cheaper fuel if the Minister's ideas are carried into effect. The State has taken control of everything at Powlett. It will not sell any freehold in the mining township; consequently all the stores are being built on leasehold lots. Having got a taste of the State pap the people want roads, culverts, foot-paths, and sanitary requirements, all cared for by the State without cost to them. The miners have objected to the hewing rate of 3s. 6d. per ton fixed by the mine manager, but in that respect the Minister of Mines has been loyal to his officer. There was a rush from all parts of Australia to get employment in the State mine just as there is always a rush to get into the police force. It is early yet to say how results will turn out but they are being watched with the greatest interest. As a first step in the financing of this socialistic experiment the Government wants to write off £46,000 out of £90,000 already spent in the mine because it was 'emergency expenditure' to enable the requirements of the Railway Department of the Newcastle to be met during the strike. As the output of coal from Powlett during that strike was 4000 tons, the cost of the emergency rush was £11 per ton of coal—a nice price to pay when it was obvious to all that the field could not possibly produce coal until long after the strike was likely to be over.

Eastern Australia.

In this connection it may be of interest to give the Western slope of the United States the news that the miners are understood to be prepared to throw the coal mines there idle in September or November.

The mining world has had a sensation over the Mt. Maroomba field in the Northern Territory. The exact locality of that district is in what is known as Arnhem's Land on the western side of the Gulf of Carpentaria. The country is practically terra incognito, but in May last a couple of prospectors turned up in Melbourne with some rich samples of galena and a story of huge outcrops 500 ft. wide and thousands of feet long, rich in ore. Some of our mining men, attracted by the story, formed a prospecting company and sent up Andrew Wilson to inspect the area. The country is 300 miles from any settlement and a fortnight's sea voyage has to be taken from Melbourne to reach Port Darwin in the Northern Territory whence prospectors start. Long before Mr. Wilson reached the field people having friends at Port Darwin sent men thence to the locality. These got back to that town with even more booming statements of the richness of the field than those of the original prospectors. The big outcrops were there and the lead and the silver as well. So a market boom set in and £10 shares jumped to £185. Then the idea occurred to some people that after all Mr. Wilson might

not be so favorably impressed as the men who had made their way to the field, pegged out claims, and got shares in the companies formed. The public then started to mark time and a gradual sagging of prices took place. As it happened Mr. Wilson did not approve of the field. In fact he advised his principals to throw up their options. This advice coming from an independent source settled the market and the field. Shares dropped £80 in 24 hours and now are salable at £2 while most of the companies are thinking about winding up their affairs or of going farther afield. The truth is that the outcrops are huge masses of diorite with a little galena showing. There is also some limestone with galena but insufficient to make the district a mining field of the least promise.

The greatest mine in Australia today is without doubt the Mount Morgan, in Queensland. Gradually the oxidized ores are being exhausted, and now instead of it being a purely gold mine of vast size it is becoming a great copper producer. The mine for the first time for many years has produced over £1,000,000 worth of product within the twelve months and it is certain that this output will be steadily augmented. The total output of metals from Mount Morgan since the inception of the company in 1886 has returned £16,026,924, and of this sum £7,479,167 has been distributed in dividends. The company now is about to start the use of a 2% copper fluxing ore from the Many Peaks field so that it will become still more important as a copper producer.

NEW YORK

Improved Conditions. — Copper Merger. — Copper Producers' Figures.—Giroux.

The week-end holiday coincident upon the celebration of Labor Day was warm to suffocation throughout the East, with the result that those who were out of town postponed their return and the nominal close of the vacation season was emphasized by a lull in market doings more complete than in midsummer. There is a better feeling apparent, a belief that some partial resumption of activity must soon make itself felt. The material progress made in so many mining centres must prove a factor for the betterment of mining markets. The Eastern markets devoted to mining shares have not kept pace with the physical development of the properties in many instances, on the other hand there have been some cases of market movement not at all justified by mining progress or prospects. There is a steady improvement apparent in the mining-share market in New York, when a survey covering a period of years is made. There is now all the necessary public interest; the elements that are needed is such publicity and assurance of good faith as will beget a proper degree of public confidence. The situation as to the general market is much mixed, the political agitation, important impending Supreme Court decisions, the possibility of drastic tariff revision, the evident over-extension of the automobile industry, the western-land speculation and the consequent tying up of bank funds in real estate, are all elements which have vital effect upon the market and upon the financial atmosphere. The assurance of a fairly abundant crop is offset in large part by the increasing cost of necessities, so that this fundamental factor does not control in face of the adverse elements which make the future uncertain and effectively forbid the present launching of new constructive enterprises.

The copper merger would have been completed months ago had it not been for the unpropitious outlook. The stumbling blocks in the way of the copper merger were possibilities rather than actualities, but none the less effective. That the scheme is now being gradually worked out is quite apparent. The dissenting minority in Cumberland-Ely withdrew their opposition to the consolidation with Nevada Consolidated, and the final dividend checks in liquidation of the company, being $6.16 per share, have been distributed. The announcement is now made semi-officially that the Utah Copper Co. has acquired in the open market enough stock of the Nevada Consolidated to give the former absolute control. James Phillips, Jr., president of the company, who waged a merry war last winter against the proposed consolidation and succeeded by a narrow margin in preventing its consummation, will undoubtedly find himself in the minority when the Utah Copper people again reach out for Nevada Consolidated. While there is a truce prevailing between the Utah Copper-American Smelting & Refining interests and the Anaconda-International Smelting & Refining companies, and common cause is made in instituting a curtailment of copper output, there is nevertheless to be seen the quiet strengthening of an outpost here and there, and the unostentatious alignment of hitherto wholly or partly independent factors. For instance, Roscoe H. Channing is assuming the duties of consulting engineer for the Utah Con., one of the principal Standard Oil properties. Utah Con. has broken away from the American Smelting & Refining Co., and the Tooele plant of the International Smelting was built largely to handle Utah Consolidated ores. This alliance is not new, but the fact that R. H. Channing is to utilize a portion of his time in behalf of the General Development Co. marks a harmony between the latter and the Standard Oil forces, which is confirmed and emphasized by the recent news that the Miami concentrate, from the new mill to be started January 1, instead of going to the Copper Queen smelter at Douglas as was reported some weeks ago, is to be shipped to the Greene-Cananea plant in Sonora, Mexico, for treatment. The old Greene Consolodated plant has been almost completely rebuilt, and on the present copper market the Greene-Cananea management may be well content to employ the smelting plant on outside ores. This contract marks a closer relation between the General Development Co. and the Cole-Ryan-Amalgamated Copper-Standard Oil family. The General Development Co. is to make Miami its first big copper producer, but it controls several others, among them the New Keystone and the New Planet; all of these must now be counted as a part of the phalanx arrayed against the Guggenheims. Whether the battle in the end is to be fought out in the open markets or in the private offices of the bankers remains to be seen, but the real question as to who is to dominate the copper market, and who is to be the world's largest smelter man has not been decided. The moves in the struggle are interesting and the attack and defense are like a Brobdignagian game of chess. When Heinze was standing the State of Montana on its head and entangling the camp of Butte in lawsuits until it resembled a procession, marching through the financial district of New York enmeshed in miles of 'tape' thrown from the windows of skyscrapers, it was said that every lawyer, politician, and miner was branded either with 'kerosene' or 'pickles.' Apparently some similar distinguishing mark will soon be necessary to designate the status of nearly every copper property in the country, save those controlled in Boston.

The August figures of the Copper Producers' Association were expected to give something of a line upon the effectiveness of the recent restriction of output. It is really too early to expect such results to show in refinery figures, from which sources the association collects the greater part of its data. Next month's showing will be a much better criterion. For August the production was 127,803,618 lb., as against 118,370,003 for July, and 127,219,188 for June. From the figures given it will be seen that the July output was under the normal, though the curtailment policy was not at that time actually in force. The proper analysis would consider August output as representing more largely the mine output of June. This does not apply, of course, to figures covering individual mines or smelters, like the monthly production of Butte, for instance, where the exact tonnage of the various mines is known. The total consumption for the month of August was 129,563,051 lb. The decrease in the sulplus was, therefore, 1,759,433 lb., being the first decrease registered since April. The heavy export demand was the chief factor in the reduction of accumulated stocks; the output being divided, 67,731,271 lb. for domestic consumption and 61,831,780 for export. Only three times during the current year has the export demand ex-

ceeded 60,000,000 lb. for any month: in January exports were 81,691,672 lb.; in June 65,895,948. Taking into consideration the record figures in production, the principal sellers of copper metal report themselves as fully satisfied with the present showing, holding that in sixty days the restriction of output will make itself felt and that then the market should be considerably firmer. In the meantime, so long as the present rate of consumption is maintained, the situation is improving somewhat. At the meeting of the Copper Producers' Association, James McLean, of Phelps, Dodge & Co., Inc., was elected chairman of the Association, is place of T. L. Livermore, whose recent retirement has been noted. Mr. McLean's place on the executive committee of the Association was filled by the election of Rudolph Agassiz, of the Calumet & Hecla. J. D. Ryan, recently returned from Europe, has gone to Butte and is looking after the working of his plans for cultailment formulated at the London conferences, in which he took a prominent part. Butte is to curtail 15%, but is to keep all miners working hoisting a lower grade of ore. Some economies, put into effect since the Butte merger, permit of this being done without cutting profits. Butte costs now average 9c. The production of the two smelters of the Anaconda is to be kept at about 270,000,000 lb. per annum, while the mines are to be put in shape for increased production should the metal market justify it. The Federal Government is making an effort to end the smelter-fume trouble in Montana, and George W. Wickersham, U. S. Attorney General, is in Butte to make a personal examination at the smelters, in connection with the equity proceeding brought by the Government against the Anaconda Copper Company.

One of the interesting developments of the mining situation is the growing recognition of the right of the stockholders and the public to know something of physical and financial conditions. The Cole-Ryan management was under fire in regard to North Butte until a statement was forthcoming. The same interests have recently had to come into the open in reference to Giroux. Giroux was expected to begin shipments about September 1, or when the Tooele smelter was blown in, but nothing was done nor was any report made public. The market has noted a good deal of selling pressure in Giroux, and the impression gained ground that some of the selling was for company account. The management has now seen fit to take the public and the shareholders into its confidence, in the statement that the company has no occasion to go into the market directly or indirectly. As to the physical conditions, it is stated that the old Alpha shaft of the Giroux, sunk in the limestone, is altogether unsafe; that the new five-compatrment shaft is now down to the 1200-ft. level and is to be sunk to the 1400-ft. point. From each of these levels drifts are to be run to the ore partly opened in the Alpha shaft.

LONDON

Carn Brea & Tincroft.

One of the famous companies working tin mines in Cornwall, the Carn Brea & Tincroft, has arrived at another crisis, and additional capital must once more be provided. For many years the ore has been too poor to yield substantial profits, let alone provide funds for expansion and development. For some time it has been acknowledged that a liberal supply of new capital has been required, but the necessary steps to meet the situation have been postponed owing to the inauspicious circumstances connected with Cornish mining. In addition, the discoveries of higher-grade ore a year ago enabled the company to increase its output considerably, and the directors hoped thereby to weather the storm for the time being. However, the grade has once more fallen and the situation becomes acute. To have an independent opinion of the position of the property and its prospects, the directors asked R. Arthur Thomas, of Dolcoath, to make a thorough examination. His report is appended to the directors' report for the past half-year now issued. During the half-year under review 38,797 tons of ore was raised and 491 tons of tin concentrate was produced. During the corresponding period of 1909, 36,825 tons of ore yielded 568 tons of concentrate. The relative production per ton was 34½ lb. a year ago and 28½ lb. during the first half of 1910. The relative amounts realized and the prices per ton were £39,428 and £37,145, and £69 and £75. Sales of other products, arsenic and wolfram, brought the total income to £39,652, and the expenses were £40,157. Lords' royalties amounted to £1422, so that the loss for the half-year was £1927. During the last ten years, the only time when anything like satisfactory profits were made was during the boom from the middle of 1905 to the middle of 1907; before and since the balance has generally been on the wrong side. Another disadvantage under which the mine labors is the absence of modern dressing plant for removing wolfram; consequently the price obtained by the sale of concentrate is lower than the average received for Cornish produce. The amount of available cash capital is now less than £5000. Mr. Thomas' report begins by a review of the history of the property and shows that since 1896, when limited liability was adopted, £132,000 has been raised and spent on the four mines, Carn Brea, North and South Tincroft, and Cook's Kitchen. Of this sum about £100,000 has been spent on development; £5000 on new surface plant, a similar amount on repairs and renewals, and the remainder has gone in wiping out adverse balances. During the fourteen years the developments have amounted to 28,400 ft. or double what was expected would be necessary; nevertheless it was never possible to keep development much ahead of mill requirements. The only time when sufficient profits were made to provide a dividend was in 1906 when about £4000 was distributed on the preference shares. The compauy has the disadvantage of having two lords who own the mineral rights. The Basset estate owns Carn Brea and Cook's Kitchen, and the Clifden estate, North and South Tincroft. At the present time the production is distributed thus: 19% from Carn Brea, 43% from South Tincroft, 38% from North Tincroft, and nothing from Cook's Kitchen. Each mine has its separate stamps and dressing floors. The crushing plant consists of old Cornish stamps amounting in all to 244 head, of which 96 are at Carn Brea, 88 at South Tincroft, and 60 at North Tincroft. As the Carn Brea output is not sufficient to keep more than half its plant in operation, some of the ore from the other two mines is mixed with it. It happens that Carn Brea and South Tincroft ores are fairly clean, but that from North Tincroft carries much wolfram, arsenic, and copper, as well as tin. Mr. Thomas animadverts on the policy of mixing these ores in treatment and makes the suggestion that in future the North Tincroft ore should be treated separately and a magnetic separator introduced for the removal and recovery of the wolfram, as is done at other mines in the neighborhood. Such an alteration in treatment would not cost more than £2000, and the immediate result would be the production of high-grade concentrate from Carn Brea and South Tincroft, that would command a better price than at present; the eventual profit to be obtained from the North Tincroft ore cannot be exactly gauged until expirements have been made. Mr. Thomas would also scrap the whole of the stamps and the buddles, if the reserve of ore warranted the expense of new plant; but the mines do not warrant so great an expenditure at surface at present. No work has been done at Cook's Kitchen for some years. The shafts, however, are kept in good state of repair and the water is not allowed to rise above the 2100-ft. level chiefly for the benefit of the other mines. The cost of pumping is heavy, amounting to £15,000 per annum, a figure which does not include any allowance for depreciation or a share of general expenses. Mr. Thomas describes the state of the various workings and comes to the conclusion that the present rate of extraction can be maintained for some time; in fact, in South Tincroft there are bodies of ore that could be more extensively worked than at present. He is of opinion that the duty of the stamps could be increased, and more ore treated, and he also points out that a better selection of the ore going to the stamps could be made by more efficient removal of waste.

General Mining News

ARIZONA

COCHISE COUNTY

The top workings of the Briggs shaft of the Superior & Pittsburg Copper Co., at Bisbee, have been closed down and the ore tributary to this outlet will be handled through the Hoatson. The laying-off of a few surface men does not indicate that there will be any curtailment of work underground and development will be carried forward as in the past.——The Cochise Gold Mining & Milling Co., operating twenty-six miles east of Benson, has opened a shoot of free-milling ore 15 ft. wide.——A churn-drill has been taken to the Great Western property in the Courtland district and prospecting with it will be started at once.——The face of the adit at the Bernoudy group at Paradise is entirely in ore that is worth about $3 per ton, and it is expected that the grade will improve considerably when the contact with the limestone is cut.——Assessment work has been started for the year on the Sweeney group.——After a year of continuous work the 1000-ft. level of the Tombstone Consolidated property has at last been unwatered and the pumps there are now in order to hold their own against the flow. The old drifts are being opened and new development started to block out the ore necessary to keep the 40-stamp mill in operation.——A body of ore assaying as high as 47% zinc and 17% lead has been opened on the group of claims in the Huachuca mountains owned by G. J. McCabe, L. C. Shattuck, and Frank Johnson.

GILA COUNTY

(Special Correspondence).—Development at the Arizona Michigan property in the Globe district for the past month has been satisfactory both from the standpoint of speed and exploitation. On the foot-wall side of the vein in the Telfair cross-cut a winze has been started which is down 13 ft. At the same time it was decided to drive both ways on the foot-wall side of the vein from the cross-cut. These drifts have progressed 20 ft. or so on either side. The Telfair cross-cut is out 1246 ft. from the shaft.——Monthly development for August underground at the Miami mine has amounted to 1000 ft. approximately which is about one-quarter of the amount during the active exploration of the mine. There are about 40 men employed in the workings on and above the 420-ft. level and a portion of these are completing the concrete work and the reinforcement of the underground ore-bin at the shaft.——The development in the McGaw shaft at the Superior & Boston property has taken it to a depth of 831 ft. which is 11 ft. below the point where the station will be established. The shaft has been discontinued for the immediate present and all attention is being directed in the construction of the station on the 820-ft. level.——As soon as the station is completed, sinking will again be started and coincident with this a cross-cut to the Great Eastern vein will be driven.

Globe, September 10.

MOHAVE COUNTY

The Little Jimmie group in the Union Pass district has been sold to Los Angeles interests by James Dundon.——T. B. Scott, who is interested in the Lucky Boy and Bright Days properties in the Chloride district, is inspecting the mines and it is probable that work will be resumed on the groups at an early date.——H. M. Bowen has made the third payment on the Belleflower mine to Rothe & Oleson and will resume operations. The shaft will be sunk to a depth of several hundred feet and the vein prospected.——A cross-cut on the 350-ft. level of the Pilgrim mine has been completed which opened a body of free-milling ore on the foot-wall of the vein.——The work of sinking below the 300-ft. level of the C. O. D. mine is well under way and the old works which contain a large amount of ore will soon be tapped and drained.——An $18,000 bar of bullion which represented the clean-up from a six days' run was forwarded a few days ago from the Gold Road mill.——The group owned by Holmes & Warner in the Secret Pass district is being sampled for Colorado interests.——The shaft at the Cyclopic mine is down 100 ft. and cross-cuts are being driven to intersect the veins between which the shaft was sunk.

PINAL COUNTY

(Special Correspondence).—The property of the Reward Consolidated Mining Co., in the Vekol mountains south of Casa Grande, has been sold to Finney & Brooks of Los Angeles. The adjoining Republic group also has been acquired and the Vekol Range Copper Co. organized. Title to both properties has passed to the new company, the officers of which are Charles E. Finney, president, and Robert J. Simpson, secretary and treasurer. The claims have been operated at various times since 1881 and a large amount of copper ore has been extracted and smelted at the property. Finney & Brooks also have acquired 15 claims adjoining the property of the Ball Copper Co. in Gila county. The London Shamrock Co. has been organized to take title to the property. The Ball Copper Co. of Arizona, which now owns the Pivot group adjoining the London-Arizona, has contracted to purchase a controlling stock interest in the Vekol Range Copper Co., and the London Shamrock Company.

Casa Grande, September 10.

YAVAPAI COUNTY

The Logos mine, eight miles southeast of Mayer, has been taken over by L. D. Hall and a force of men started on development. There is a 180-ft. shaft, another 100 ft. deep, and a 200-ft. drift on the property, together with a hoist and camp buildings, so no time will be lost in making surface improvements.——A 20-hp. gasoline hoist has been installed by the Swastika company which owns the Black Prince and Warrior claims and a large amount of development is planned under the supervision of F. W. Wood.

YUMA COUNTY

The King of Arizona mine at Kofa, the control of which is owned by Eps Randolph and E. S. Ives, has been closed down as the ore, which has made the property one of the best producers of that district for the past ten years, has become too low grade to put through the mill.——The shaft at the Silent King property has opened a number of rich stringers in the vein and ore assaying as high as $2500 per ton has been obtained.——All the construction work has been completed at the Clara Consolidated and the construction crews laid off. Development will be carried forward on a larger scale as a new hoist has been installed at the No. 5 shaft and sinking is being hurried.

CALIFORNIA

AMADOR COUNTY

The shaft at the Lincoln mine has been retimbered to the water level and an electric pump installed. Work will be continued in the shaft as fast as the water is removed.——A head-frame is being erected at the Rose claims and development started.

CALAVERAS COUNTY

N. B. Harris, of Montclair, N. J., has purchased the Lightner mine at Angels Camp for $200,000, and will spend $50,000 in development, the work to be started at once. The property has been examined by F. L. Lowell under the direction of Francis Drake, W. G. Devereux, J. R. Farrell, R. C. Shaw, and A. M. Yonge who estimate 500,000 tons of ore in sight. The mine has a record of $650,000 disbursed in dividends during the past ten years under the management of Alex. Chalmers, who will continue in charge of the mine.——There is 20 tons of ore on the dump at the North Star mine near West Point and the shaft is down 45 ft.——C. Gilbertson has opened the vein of the Morning Star claim on the 40-ft. level showing it to contain a high percentage of sulphide.——A shipment of 50 tons of first-class ore has been forwarded to the smelter from the Newman mine and about 150 tons of second-class piled on the dump.——Machinery is being placed on the Star of the West property by Stanley Barnhart and the shaft will be reopened.——Operations have been resumed at the Buena Vista group.

INYO COUNTY

A report has been mailed to the stockholders of the Casa Diablo Mining Co. stating that the company has approximately 50,000 tons of ore blocked out and that new machinery has been ordered to facilitate the handling of it. An examination of the property has just been completed by A. L. Carter who recommends the development of the lower levels of the mine and the installation of a cyanide plant.

KERN COUNTY

Well No. 56 of the American Oilfields Co. in the Midway district which was brought in about a month ago has commenced spouting at the rate of 15,000 bbl. per day.——The Consolidated Midway's well No. 1 is being held down to a production of about 30,000 bbl. per day although the well is capable of producing nearly double this amount.

LOS ANGELES COUNTY

At the meeting of the Western Oil Producers' Association held at Los Angeles September 8, S. C. Graham, the secretary, resigned as the majority of the directors elected were opposed to the conservation policy approved by Mr. Graham.

MARIPOSA COUNTY

The Marble Springs Mining & Milling Co. has secured a bond on the Marble Springs mine, near Coulterville, and will unwater the property which has a good record for past production. The company, for which F. M. Bernou is manager, has also taken the adjoining North Fork group of 14 claims under bond. There is a 10-stamp mill on the latter property.——Teamsters are busy hauling the machinery from the Mt. Jefferson mine near Groveland to the Hites Cove property.

NEVADA COUNTY

The Pittsburg Gold Mining Co. has commenced sinking at the 1150-ft. level of the shaft and will continue to the 1350. The company is using electric power for hoisting so there is little likelihood of any interruption to this work due to the shortage of water though the water company has announced that the supply is running short.——The Tarr Mining Co. is constructing a large dam east of the Prudential mine that will hold a supply of water for the mine. The tailing from the sluicing will be raised by a hydraulic elevator and run behind restraining dams.——The adit on the property of Otto Woehler, at Spenceville, has opened a 10-ft. vein of copper ore and a number of samples have been shipped to determine the value of the discovery.

PLACER COUNTY

S. D. Valentine and J. L. Bryson have been examining the Big Oak mine near Colfax with a view to reopening the property which has not been worked for about fourteen years.——The drift has been completed across the front channel at the Red Sea gravel mine and has been started toward the back channel.——Good ore is being opened on the 100-ft. level of the Three Queens mine by M. Savage who is developing the property.

SIERRA COUNTY

Development has been resumed at the Kate Hardy and a drift is being driven on one of the lower levels to get under the rich shoot that was opened a short time ago.——J. G. Jackson and P. W. Smith have secured a bond on the Brown Bear, Brown Bear No. 2, and Brown Bear Tailing claims and are driving the adit to tap the gravel. Orders have been placed for 2000 ft. of steel rail and 1000 ft. of air-pipe.——Davies & Fippin have opened a shoot of ore, samples of which assayed as high as $1000 per ton, on their claims near Mountain House. An adit is being driven to tap the vein at greater depth.——High-grade arsenical pyrite has been opened at the Cremorne mine about five miles from Alleghany.——S. W. Van Syckel has secured a bond on the Hayes mine near Sierra City and has commenced development under the direction of William Barker. The Hayes was one of the early-day producers of this district and is equipped with a 20-stamp mill. A new compressor and air-drills will be installed at once to hurry the work of development.——A track has been laid to the mill at the Empire mine in Gold Valley and the ore is being crushed.——Machinery for the electric-lighting plant at the Bunker Hill mine has arrived and is being installed at the property.——Charles Brown has stopped work in the shaft at the Code property and will drive an adit that will tap the vein at a depth of 400 ft. It is estimated that it will take 600 ft. of driving to complete this work. The vein in the bottom of the shaft is 28 in. wide and assays $13 per ton.

SISKIYOU COUNTY

The Highland mine near Etna Mills has been sold and the new owners are to spend a large amount on development and the erection of a mill.——Several sacks of high-grade ore has been shipped from the Overton mine for treatment and it is reported that this property is developing one of the best shoots in the Russian Creek district.——A new company has taken over the management of the Wright & Fletcher placer property and will install new apparatus under the supervision of Charles Fry.——Gardner & Weed made the final clean-up on their placer claims for the season with excellent results.

TRINITY COUNTY

The Trinity Dredging Co. has a crew of surveyors running a line for the ditch that is to convey the water for the power plant and dredge. A fall of 280 ft. will be obtained and nearly 1000 hp. developed. The company owns 850 acres of land and has ordered machinery for the equipment of the dredge and plant.

TUOLUMNE COUNTY

(Special Correspondence).—A discovery recently made in the Sunny South mine, two miles north of Tuolumne, has revealed facts which will likely involve the property in litigation. An option for a bond was given to C. E. Connally by the owner, L. Bacigalupi, of Sonora, who subsequently bonded the property to other persons at a great advance on the original sale price, and both parties now claim right to possession. The ore was opened not far below surface. The vein is 9 ft. wide and will average, in its entire width, not less than $10 per ton.——The Central Mother Lode Gold Mining Co. has made final payment on the Mangante mine, situated near Jamestown. The company has extensively developed the property, which is now rated among the most promising in this county. It is reported that the company will be reorganized, with a greatly increased capitalization, and that operations will in the future be conducted on a much larger scale than in the past. Machinery is to be purchased at once to handle the flow of water in the mine, which of late has become unusually large.——It has been repeatedly rumored that negotiations involving the sale of the App and Rawhide mines had reached a successful conclusion and that the new owners would shortly assume charge of the properties, but as yet nothing certain or definite has come to light.——Mining operations have been suspended for a few days at the Harvard in order that the necessary annual repairs may be made. The Harvard is not affected by the shortage of water, as it gets its supply from the Gale ditch, which is fed by springs which flow the year round.——Several men are employed in putting up a 4-stamp mill at the Italian Camp mine, situated one mile west of the Belieview and owned by Andrew McCormick, Joseph Rolleri, and John Froli.——The Empire mine, on the same vein as the Providence, and formerly known as the McKinley, is being unwatered for thorough inspection. The property was recently bonded to L. H. Jansen, whose intention is to install the necessary surface equipment for its development if the showing proves satisfactory.——The crew which is sinking the Longfellow shaft is to be increased to 18 men and it is the intention to go down 1000 ft. before driving new drifts.——The Volich mine, on Bald mountain, has been leased to J. J. Barkla and E. Stephens, who have commenced work at the property.——A brief suspension of operations was caused at the Mack mine by the breaking of the compressor shaft, but there was no unnecessary delay in the resump- of work.

Tuolumne, September 12.

COLORADO

CHAFFEE COUNTY

V. J. Barrett and J. J. Burns, of Pueblo, leasing on the Moose mine recently made a rich discovery of gold and silver ore. Assays have run as high as 22 oz. gold and 60 oz. silver, but the average value is between $125 and $200 per ton. A shipment is now being prepared and will be sent to the Eiler smelter in a few days.

CLEAR CREEK COUNTY

(Special Correspondence).—Work on the Ruler property was put under way the first of this week. N. Williams, who has been appointed manager, states that the adit will be driven for 500 ft. to intersect a number of cross veins that are owned.——Work has been resumed on the Paragon adit, situated at the head of Bard creek. E. L. Clark of Minneapolis is manager.——The Santiago mill and sampler was completely destroyed by fire on the night of August 30. William Rogers, the manager, states that the building will be reconstructed and that the new mill will be one of the most modern constructed in Clear Creek county.——Arrangements have been perfected whereby the Rosebud property on Democrat mountain will be developed. The two adits will be driven ahead for several hundred feet.——The buildings at the Oriental adit on Bard creek have been completed and a force of men is employed driving the adit. A group of seven claims is controlled. A. Swanson is manager.——Work was resumed last week in putting through the raise from Victoria adit-level to connect with the Frostberg workings. It will be necessary to break 200 ft. of ground before the undertaking has been completed. ——F. Rowan, in charge of the installation of machinery at the Malm electro-chemical plant, has received orders from the Western Metals Co. to have the plant ready for ore treatment by November 1. As a result it will be necessary to work night and day henceforth. The East Griffith mine is receiving large development, due to the contract that is held with the Western Metals Co., wherein 50 tons per day of lead-zinc ore must be furnished.

Georgetown, September 9.

GILPIN COUNTY

(Special Correspondence).—The Star of the West mine in Russell gulch has been taken under bond and lease by T. M. Fisher of this city who has interested a number of investors. The property adjoins the War Dance, one of the heaviest producers in the county. Driving has been started from 330-ft. level of the shaft.——The Benzai at Black Hawk has been leased to H. Boellert and H. Hartman. The water is being raised from the shaft to the 240-ft. workings and development will be started from both the 100 and 240-ft. levels. The mine was a former heavy producer.——The Stewart mine in the Wide Awake district has been secured by Eastern men and work will be put under way soon.

Central City, September 10.

LAKE COUNTY

The lessees of the McRea shaft on the north side of Fryer hill, at Leadville, have unwatered the mine and are now cleaning out the old drifts preparatory to starting development.——A. Johnson and associates have completed 200 ft. of driving at the Lime property and are now preparing to ship the ore which is a good grade of iron.——The lessees of the Little Giant are working through the Yankee Doodle shaft and shipping 50 tons of ore per day.——A company has been organized to drive a long adit that will have its portal in Birdseye gulch and cut a number of veins at depth on that side of the mountain. The company, at the head of which is S. P. Fenton, will install an electric air-compressor and equipment for driving the adit 3000 ft.——The output of the Leadville district for August amounted to 74,000 tons which is an increase of 10,000 tons over July, and it is estimated from the present rate of production that this month will make a similar advance as a number of properties are preparing to commence shipment.——The new shaft at the Blanche in South Evans gulch is going down steadily. A seam of ore of good milling value was cut recently.——A heavy flow of water has been met at the Favorite and pumps are being installed to handle it.

OURAY COUNTY

The winze from the 400-ft. level at the Frank Hough property has opened the vein about 100 ft. below the level and assays have been taken which run 40% copper, 80 oz. silver, and $10 gold per ton, which is somewhat better than obtained in the levels above. Since opening the vein at this point there has been considerable talk of resuming work in the deep adit which was started to cut the ore at a depth of 1000 ft. This would bring the ore out just above the San Juan Chief mill.——Patrick Corbley and Alex. Gould, who secured a lease on the Oom Paul group a few weeks ago, have shipped a carload of ore that is worth about $80 per ton in gold and silver.——The raise from the Bagley adit at Animas Forks to the Red Cloud shaft has been started, the total distance amounting to 600 ft. This raise will open a large amount of ore on the Red Cloud vein.

TELLER COUNTY

A contract has been let by the El Paso Consolidated Mining Co., at Cripple Creek, to drive a raise that will intersect the churn-drill hole from the bottom of the El Paso shaft. The raise will be driven the same size as the shaft so when the water is drained the two may be connected and used as the main shaft of the property. The distance between the bottom of the churn-drill hole and the cross-cut is about 300 ft. and it is estimated that by working from above and below this can be completed within a month.——The Union Leasing Co. has secured a three-years' lease on the property of the Gold Sovereign Mining & Milling Co. and will take over the property from the Clements Leasing Co. which is now operating the mine about the middle of December.——September 10 was pay-day at Cripple Creek and it is estimated that $350,000 was distributed.——Two good discoveries have been made by lessees on the property of the Gold King Mining Co. in Poverty gulch within the last few days, ore being obtained that assayed as high as $1000 per ton.——Work is progressing rapidly in the retimbering of the incline shaft and the construction of mine buildings at the Last Dollar mine which is under lease to the Uncle Sam Mining & Leasing Co.——The Altman Leasing Co. has opened a body of rich ore on the 450-ft. level of the Pinto claim.——Iver Weston and associates have cut five feet of $40 ore on the Lexington company's ground.

IDAHO

IDAHO COUNTY

The second payment on the Center Star mine, in the Elk City district, has been made by the New York interests that have been developing the property since June 1. A crosscut is being driven to tap the vein considerably north of any of the present workings.——There is a small force of men at work at the Grangeville getting the property in shape for the arrival of the new machinery.

SHOSHONE COUNTY

Reports from the smelter on the second car of ore sent to the smelter from the Reindeer mine, at Mullan, show a net return of between $600 and $700. Some of the ore is stated to have assayed about 20% copper. The first car netted $200. The company has decided to erect a mill to treat the ore.——Sufficient high-grade galena ore has been taken from the Cedar Creek mine, near Murray, to make a carload shipment. Much concentrating ore has also been taken out. The excellent showing of lead ore continues. One raise was made in the shipping ore and a second raise is being driven.——Peter Vannetti, and associates, lessees of the upper workings of the Callahan mine in the Coeur d'Alene district, who shipped six cars of galena ore this summer, are preparing to double their shipments. A steam-drill plant has been installed at the mine which has shipped 29 cars of ore to date.

MONTANA

CASCADE COUNTY

In line with the present policy of economy the Anaconda

Copper Mining Co. is making some important changes in the smelter at Great Falls. The blast-furnaces are to be made larger and new reverberatories of the Washoe type installed. For some time the Anaconda company has been experimenting at the Washoe plant with Montana coal and deep fires to take the place of shallow fires and long flames produced by the Diamondville coal. The results have been satisfactory and it has been found that Montana coal, with deep fires, will do as effective and economical work as the shallow fire and Diamondville coal. While the use of

Great Falls Smelter and Chimney.

Montana coal will not work any saving, it is an achievement to be able to use Montana coal exclusively. Hereafter a direct fire will be used. With the changes being made at the Great Falls plant the capacity will be increased about 30 per cent.

NEVADA

ESMERALDA COUNTY

(Special Correspondence).—The merger of the Rawhide Queen and Rawhide Coalition has been satisfactorily arranged and the next step will be the erection of a modern mill and cyanide plant to treat the large tonnage of ore that has been blocked out in the properties. The leases will be taken up by the management as soon as possible and the entire property operated on company account.——The Federal Mines & Reduction Co. is sinking its shaft to the 300-ft. level and will open much new territory. The mine is equipped with a hoist capable of sinking 700 ft. and it is expected to complete the installation of a cyanide plant at an early date.

Rawhide, September 9.

HUMBOLDT COUNTY

(Special Correspondence).—The new mill of the National Mining Co. is ready to receive power, and will probably be in operation soon. It is understood that the shipments during August approximated $300,000. An immense quantity of ore, averaging about $5 per ton, has been stored on the dumps for treatment in the new mill.——The Causten lease reports the intersection of the Charleston Hill vein eight feet from the shaft. The ore was struck on the 100-ft. level the gold and silver values being about equal.——The Charleston Hill company has granted a lease to the Green Leasing Co. of Salt Lake, and one to William Thompson, of Goldfield. The Bankers lease is expected to strike the vein within a short time. The Defiance lease, also on Charleston Hill estate, is sinking steadily.——In the Mayflower the 500-ft. adit has intersected seven feet of ore.

Winnemucca, September 9.

LYON COUNTY

(Special Correspondence).—The management of the Mason Valley mine has decided to construct a gravity aerial tram from the mouth of the present adit, No. 4, to the railroad, a distance of 1¾ miles with a drop of 600 ft. in elevation. The Nevada Copper Belt railroad has completed its track to the head of Mason valley, and has graded to the smelter site east of Wabuska, where excavation work is in progress. The Mason Valley is contemplating using a diamond-drill to explore its vein at depth. ——The Nevada Douglas has made another $50,000 payment on the Ludwig mine, the purchase price of which was $500,000. The remaining $150,000 will not be required until the mine begins smelter shipments.

Mason, September 9.

NYE COUNTY

(Special Correspondence).—The August reports of the Tonopah mines show the camp to be in a flourishing condition. The Tonopah Mining and Montana Tonopah have maintained their usual net earnings, the Belmont has probably exceeded its surprising past monthly net earnings of $150,000, the Tonopah Extension reports a net earning of $25,000, the best month since the mill has been in operation, and the West End, which has the additional expense of shipping their ores to California smelters for treatment, reports a net earning of over $10,000. At a recent meeting the directors of the Tonopah Belmont voted a 15c. dividend, and in addition decided to construct a 40-stamp mill near their new shaft, as the present 60-stamp mill at Millers cannot handle the output. It is not considered advisable to enlarge the present mill with its disadvantageous site. The Belmont shaft, started nearly ten years ago and abandoned as a working shaft in favor of the Desert Queen, has now been enlarged to the surface as a three-compartment shaft. The work of riveting the 80-ft. steel head-frame has been completed, and the sheaves hoisted to position. The compressor has been assembled, and the hoist and compressor foundations await the delayed motors. The new ore-house and office buildings are nearing completion. Another month should find all in operation, which, besides giving ample working facilities and better ventilation, will mean a direct saving in cutting the tramming distance of ore and waste 800 to 2000 ft. Except the east drift on the 1100-ft. level in which the fault has been found to be of greater extent than at first anticipated. all the development drifts on the Belmont have added to the ore tonnage in sight.

Tonopah, September 10.

WHITE PINE COUNTY

The south cross-cut from the Eureka shaft on the 465-ft. level of the Ely Central mine has opened a number of stringers of porphyry in the limestone which show a good copper content. These are thought to be stringers of the main body of porphyry ore.

WASHINGTON

STEVENS COUNTY

H. E. Schleiff, of Berlin, who has just completed a thorough investigation of the deposits and development in the three camps in this county, situated from 40 to 75 miles north of Spokane, declares that within its confines is the largest and most promising tungsten field in the world. He said: "The tungsten district in Stevens county has a chance to overshadow Boulder county, Colorado, in the next few years. Boulder county is the country's chief producer, having an output of from 3000 to 4000 tons of concentrate per year. Three camps are under development. One is the Germania in Cedar canyon, thirty miles north of Springdale; the Tungsten King, eight miles north of Deer Park; and the Blue Grouse, a mile south of the Tungsten King and eight miles from Loon lake.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The Consolidated Mining & Smelting Co. is about to begin mining operations at the Molly Gibson mine, Kokanee, and has shipped a carload of haulage machinery to that property from its Rossland machine shops. The company has turned the old slime plant at the St. Eugene mine into an experimental mill for the handling of the ores from its various mines. The plant has a capacity of 50 tons per day and will be used to ascertain the different methods of treatment that will be necessary to reduce the more complex ores of the company's mines.——A strong party of capitalists on the Coast has bonded most of the mineralized ground on Toad mountain near Nelson and will, after a careful examination, commence active work in the spring. The property acquired includes the assets of the Hall Mining & Smelting Co., the Silver King mine, the Nelson smelter, machinery, and tools; also the ground of the Dandy and Ollie mines, Starlight mines, and the Kelly, Rand, Buchanan, and Lennie mineral claims, the whole comprising 40 mineral claims or nearly 1500 acres of mineralized ground.——A. G. French, consulting metallurgical chemist, who has had a lengthy experience in the treatment of lead-zinc ores at Swansea, Wales, is in this district studying the situation with a view to aiding in the solution of the local zinc-smelting problem.——The Maestro mine, near Ainsworth, which was shut down upon the death of the owner a couple of months ago, has been opened again, with Alex. Green in charge.——An effort is being made by the coal miners of southern Alberta and the Crows Nest district to obtain reciprocity in the matter of coal entering the United States from those points. It seems that the mines have reached the capacity of the market in domestic coal, while the supply is practically unlimited. The best domestic coal brings $3.85 per ton in Alberta, while the price in Winnipeg and Montana is about $8, because of high freight rates and duty. The chief obstacle is believed to be Nova Scotia, which demands protection from the coals of Pennsylvania and Virginia.——The syndicate which last fall bonded the Ikeda Bay mines has been reorganized as a stock enterprise, the authorized capital being $850,000 in shares of $1. The second payment on the bond has just been made, amounting to $30,000. The Japanese owners have agreed to take stock in the new concern for the balance of the purchase price, excepting a payment of $12,000 due in March. Andrew G. Larson, consulting engineer, of Vancouver, will have charge of the development of the two new veins found in his development by diamond-drilling. The power plant will be enlarged and a 2000-ft. tramway built from the adit. The 6500 tons shipped from this property by the late Japanese owners assayed from 4 to 5% copper and about $3 gold. The ore is self-fluxing and can be mined and smelted economically. Freight rates to Ladysmith smelter will average about $3.50 per ton, and a treatment rate of $2 can be obtained.

Rossland, September 10.

MEXICO

SONORA

The Cia. Metalúrgica y Refinadore del Pacifico, S. A., has purchased the lead smelter at Guaymas. A number of changes will be made at the plant to put it in first-class condition and bring it up to date.——The first unit of the concentrating mill, having a capacity of 60 tons per day, has been successfully installed at the Santo Domingo mine in the Alamos district and is running full blast. The superintendent of this mine, James R. Hendra, reports that an excellent grade of lead-silver-copper concentrate is being produced. This mine, controlled by the Sonora Central Mines So., has been systematically developed over a period of three years, and has in the neighborhood of 3000 ft. of work, most of which is in ore. It is proposed to enlarge this concentrating plant to a capacity of 150 tons per day. The company has a working force of over 100 men. It is estimated that the earnings of the mill will be in the neighborhood of $15,000 per month.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

TITLE TO MINING CLAIM—TRANSFER OF INTEREST BEFORE PATENTING

Patents from the Government to mining claims are frequently obtained in the names of the original locators without regard to intervening changes of ownership; and the fact that a corporation grantee of certain owners proceeded upon an application made by prior owners, and obtained a patent to themselves, did not estop such corporation grantee from asserting that the interest of one of such patentee had been forfeited pursuant to the statute and vested in the other grantors prior to the patent.

Van Sice *v.* Ibex Mining Co., 173 Fed. 895, Oct. '09.

VALIDITY OF STATUTE FORFEITING INTEREST FOR FAILURE TO WORK

The United States Statute providing for the extinguishment of the interest of a part owner of a mining claim for failure to contribute to the assessment work required by such statute, is constitutional and valid, and a forfeiture under this statute will be enforced by a court of equity when such relief accords more with the principle of right and justice than would the denial of the relief prayed for. The other beneficial owners are the proper parties to give the notice to such part owner under the statute to forfeit his interest for a failure to contribute to the assessment work.

Van Sice *v.* Ibex Mining Co., 173 Fed. 895, Oct. '09.

MINING LOCATIONS—'GRUB-STAKE' CONTRACT

Under a 'grub-stake' contract a third person agreed to furnish the locator of a mining claim with supplies and in consideration thereof was to have an interest in the claim. In a controversy as to the rights of the parties it was held that the contract was not impaired by the fact that after obtaining certain goods and supplies on the credit of such third person the locator paid for such supplies himself. If, as a matter of fact, the 'grub-stake' contract did exist between the parties at the date of certain locations, and pursuant thereto such third person did furnish, according to the contract, necessary supplies to the locator, the right of the former to an interest in the property located during the life of the contract attached, although the locator did not locate any of the claims in the name of himself and such third person as equal owners according to the agreement.

Byrne *v.* Knight, (Cal.) 106 Pac. 593.

INJURY TO MINER—DUTY OF MINE OWNER

The rule of law that a master shall furnish a safe place for his servants to work, was applied where the lighting of a passage-way in mine was necessary for the safety of the miners to enable them to do their work and to get to and from their work safely, and the failure of the mine owner to maintain the light because of the negligence of a servant did not relieve such mine owner from liability for injury to a miner. In such case the mine owner was held liable for the negligence of the person he employed to maintain the light, and a miner who had no actual knowledge of the danger in such pathway did not assume the risk, unless such danger was obvious to the person of ordinary prudence in the same situation, and such that it would not escape ordinary careful observation. The rule is also that the mine owner must furnish a suitable place where the miner with due care may perform his work without being exposed to any but the ordinary dangers of the occupation; and he is not required to familiarize himself with all the machinery or appliances which he himself does not use, and he may presume that his safety has been reasonably provided for. But whether the miner, injured by falling into a hole in the unlighted pathway in the mine, was guilty of contributory negligence, was held to be a question of fact to be determined by the jury.

Kaukola *v.* Oliver Iron Mining Co., (Mich.) 124 Northwest. 591, Feb. '10.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

CHARLES JANIN has gone to Mexico.

MARK R. LAMB is in New York City.

R. S. RAINSFORD was in San Francisco.

W. M. KNOX is at Diamantina, Brazil.

R. D. SALISBURY has been in San Francisco.

T. H. OXNAM has gone to Grants Pass, Oregon.

R. B. MARSHALL was in San Francisco this week.

H. F. LEFEVRE will be in Guatemala for two months.

R. H. CAMPBELL has again taken up his residence in San Francisco.

CARL F. DIETZ, of Dietz & Keedy, has returned to Boston from Europe.

W. S. LARSSEN, of Helena, Montana, is examining mines near Boise, Idaho.

R. VAN A. MILLS has gone to Tientsin, China, where he will be at the Imperial University.

M. A. NEWMAN, manager for the Cia. Minera Jesus Maria y Anexas, is in San Francisco.

ERNST WIENER has returned to New York from Europe, where he has been several months.

STANLEY C. HAROLD is assayer and surveyor for the MacNamara Mining Co. at Tonopah, Nevada.

FOREST B. CALDWELL is engineer in charge of the Candelaria Syndicate, at San Dimas, Durango, Mexico.

FRANCIS A. THOMSON recently made several examinations in Sanders and Missoula counties, Montana.

E. H. WEBSTER has resigned the management of the La República mine, Ocampo, Chihuahua, Mexico.

ROSS B. HOFFMANN returned from Colorado and has gone to make as examination in Tuolumne county, California.

E. K. SOPER has returned to Minneapolis after spending the summer in the iron and copper ranges of the Lake Superior district.

PHILIP WISE, of Los Angeles, who has been spending the summer in Europe, returned to New York on the 16th on the *Mauretania*.

MARSHALL D. DRAPER and JOHN GROSS have formed the firm of Draper & Gross at 746 Equitable building, Denver, and will do a general mining and metallurgical engineering business.

HOWARD THROCKMORTON has opened offices at Bakersfield, California, and at Mills building, San Francisco, for examinations, reports, and surveys, and supervision and management of oil properties.

FREDERICK A. HOFFMAN, general manager for the Hydraulic Supply Mfg. Co., died this week at Seattle after a brief illness. He founded the Pacific States Pipe Works in San Francisco and four years ago moved to Seattle, where he organized the Hydraulic Supply Manufacturing Company.

COPPER PRODUCERS' FIGURES, AUGUST

For the first time since April the figures of the Copper Producers' Association showed a decrease in the copper surplus, the amount on hand being 1,759,433 lb. less than the July stock. Copper stocks on hand September 1 were 168,881,244 lb. compared with 170,640,678 August 1. The production in August was 127,803,618 lb. as against 118,370,003 in July, an increase of 9,433,615 lb. Total deliveries in August amounted to 129,563,051 lb. compared with 116,115,342 in July, an increase of 13,447,709 lb. Of the deliveries 67,731,271 lb. were for domestic consumption and 61,831,780 for export, domestic deliveries increasing 11,023,096 and export 2,242,613 lb. over the July statistics.

Recent Publications

REPORT OF THE SLUDGE ABATEMENT BOARD FOR 1909. Pp. 30., Ill. Government Printer, Melbourne, 1910.

DREDGING AND SLUICING IN VICTORIA, AUSTRALIA, IN 1909. By D. B. Sellars. Pp. 14. Government Printer, Melbourne, 1910.

PRODUCTION OF GLASS SAND, OTHER SAND, AND GRAVEL IN 1909. By E. F. Burchard. U. S. Geol. Surv., Adv. Chapter Min. Res. 1909. Pp. 26. Washington, 1910.

IRON ORE DEPOSITS OF THE BRISTOL MINE, PONTIAC COUNTY, QUEBEC. By E. Lindeman. Bull. 2, Department of Mines, Canada. Pp. 15, Ill., maps. Ottawa, Canada, 1910. A description of the iron mines on the Ottawa river, near Chatts Falls.

GEOLOGY OF THE WHATATUTU SUBDIVISION, RAUKUMARA DIVISION, POVERTY BAY. By J. H. Adams. New Zealand Geol. Surv. Bull. 9, N. S. Pp. 46, Ill., index., map. Wellington, 1910. This is a detailed study of the geology of one of New Zealand's petroleum districts.

PRODUCTION OF MINERAL PAINTS IN 1909. By E. F. Burchard. U. S. Geol. Surv., Adv. Chapter Min. Res. 1909. Pp. 22. Washington, 1910. The value of the total production for the year amounted to $613,133, of which amount metallic paint furnished $256,373; ocher, $137,880; mortar colors, $116,126; shale and slate, $58,882; and umber and sienna, $43,872.

PRELIMINARY REPORT ON THE GEOLOGY OF THE MONARCH MINING DISTRICT, CHAFFEE COUNTY, COLORADO. By R. D. Crawford. Colorado State Geol. Surv. Bull 1. Pp. 111, Ill., index, maps. Denver, 1910. This is an excellent account of the geology of a district not previously studied in such detail and marks a good beginning for the series of bulletins of this survey.

COAL BRIQUETTING IN 1909. By E. W. Parker. U. S. Geol. Surv., Adv. Chapter Min. Res. 1909. Pp. 71. Washington, 1910. Mr. Parker's annual review shows that substantial progress is being made. While the total output of briquettes is still small, 139,661 tons, plants are being operated at a number of widely scattered points and valuable experience is being accumulated at the same time that the public is being educated to the advantages of briquetted fuel.

MINING AND QUARRY INDUSTRY OF THE UNITED STATES, 1909. By D. H. Newland. New York State Museum, Bull. 142. Pp. 96. Albany, 1910. The value of the mineral production of the State in 1909 amounted to $34,914,034, a gain of more than $5,000,009 over that for 1908. While New York is not the centre of any of the major mining industries, the total value of its mine product is large and the variety of minerals won is especially striking. The industry is evidently in healthy condition.

SUMMARY REPORT, MINES BRANCH, 1909. Canada, Dept. Mines, Pub. 63. Pp. 181. Ottawa, 1910. In addition to a general summary report by the director, Eugene Haanel, this volume includes a preliminary report on the mineral production of Canada, by John McLeish; a study of commercial methods of analysis of oil shales, by H. Leverin; a reprint of the report made by Messrs. Carl Meissner, Victor Watteyne, and Arthur Desborough, to the U. S. Geological Survey on prevention of mine accidents; and a paper on the examination of magnetic ore deposits, by Howells Fréchette. Canadian mineral production now amounts to $73,917,146 per year, of which $41,774,362 comes from the metal mines. It is evident that intelligent preparation is being made for the much larger production that Canada is sure to have.

CEMENT INDUSTRY IN THE UNITED STATES IN 1909. By E. F. Burchard. U. S. Geol. Surv., Adv. Chapter Min. Res. 1909. Pp. 22. Washington, 1910. The total quantity of portland, natural, and puzzolan cements produced in the United States during 1909 was 64,196,386 bbl., valued at $51,232,979. As compared with 1908, when the production was 52,910,925 bbl., valued at $44,477,653, the year showed an increase of 21.3% in quantity and 15.1% in value. The largest increase was in the manufacture of portland cement, for which the average price was 81c. per barrel. This was 8 to 10c. higher than the average in the Lehigh district, and about 1c. higher than the average for the Central States. While production in the East continues to increase, the year marks another stage in the decline of the relative importance of the Lehigh district.

MINING CONGRESS PROGRAM

The detailed program of the meeting of the American Mining Congress at Los Angeles, September 25 to October 1, is not yet available, but the attractive circular now being distributed assures that a week of pleasure as well as important business sessions awaits the delegates. Convening Monday morning, September 26, at 10 o'clock, the day will be devoted to the formal welcomes and the shaping of the week's work. The evening will be devoted to a reception to the delegates and visitors by the Chamber of Commerce. Tuesday evening there will be a President's Reception at the Alexandria Hotel, the official headquarters. Wednesday afternoon the ladies of the Sierra Madre Club will entertain the visiting ladies at tea at the Alexandria Hotel, while the same evening, or the one following, the members of the Sierra Madre Club will give a stag reception in honor of the visiting delegates. Saturday morning's session, the last one of the Convention, will recess at 11 o'clock, the members, delegates, and visitors with their families to reassemble at 12:30 o'clock, after luncheon, to entrain for Long Beach for an afternoon together. The special trains will be held for a dance during the evening at the Virginia Hotel. Sunday all who care to will go in a party to Avalon, on Catalina Island, undoubtedly the most picturesque and interesting island port on the entire Pacific Coast, if, indeed, as many foreign travelers have claimed, not in the world. The Los Angeles Chamber of Mines will co-operate in the entertainment of guests, and extends an invitation to all visitors and delegates to inspect its mineral exhibit at its headquarters, which will be open to all.

At the Los Angeles session the report of the committee upon prevention of mine accidents, and the reduction of State mining laws to uniformity, will be given. This committee was appointed at the session of the Mining Congress held in Denver in November 1906. At each succeeding session it has reported progress, and at this year's meeting its final report will be given. The following is the membership of the committee: Walter Renton Ingalls, chairman, James Douglas, J. Parke Channing, James R. Finlay, John Hays Hammond. The report is endorsed by all of the committee. It also has been submitted to many mining engineers and mine operators for suggestions.

COMMERCIAL PARAGRAPHS

THE RIX COMPRESSED AIR & DRILL CO., San Francisco, has recently issued Bulletin No. 144, describing its prospectors' outfits for machine drilling. Numerous combinations of small compressors, gasoline engines, motors, drills, etc., are shown in detail. The outfits are particularly advantageous to those who desire to do prospecting or assessment work more rapidly and more cheaply than is possible by hand-drilling. They should also appeal to small companies desiring to change from hand to machine-drilling with the smallest initial expenditure.

THE TERRY CORE DRILL CO., 50 Church St., New York, reports a very successful record of drilling from the Plainfield Mining Co. A Class A Terry Drill was used, it being a mounted rig. Although extra expense was incurred owing to having to haul fuel and water to the drill, the cost was considerably below the estimates or expectations, it being less than $1 per foot. Two men operated the drill, working 9 hours per day. Thirteen days' work resulted in a total drilling of 235 ft. through slate and pyrite, and a 2⅞-in core was removed.

DEATH annually claims victims on the deserts of the world, and every effort should be made to mark the trails to the water holes. The U. S. Geological Survey has issued a general map of the Nevada-California desert, but additional surveys and permanent sign posts are needed. It is proposed to ask the Federal Government to undertake this work, but marking trails seems rather to be a function of the States.

REGULATION of rates over the White Pass & Yukon railway has been undertaken by the Canadian authorities. There have been charges of rebates and secret rates. At a hearing in Seattle last year the Interstate Commerce Commission declined to interfere because its jurisdiction is restricted to the United States and its 'territories,' while Alaska is officially a 'district.' The distinction is worth remembering in connection with railway building in the Far North. It is evident that away from the border shippers could not count on the good offices of the Canadian commission.

LOS ANGELES will welcome the American Mining Congress on Monday next, and through the week the Sierra Madre Club, assisted by the Chamber of Mines, will officially entertain the mining men. Unofficially the citizens will extend many courtesies to their visitors such as always leave a pleasant train of recollections after days spent in southern California. Time was when Los Angeles was thought of as a place where expatriated but thrifty Hawkeyes diligently exploited a charming climate and a much-nurtured set of Spanish traditions, to the end that hard-baked, cactus-covered ground should be transmuted into 'real estate' and town lots sold for real money. Later, all the land within the encircling mountains having been platted, and fashions changing, mining stocks and oil 'securities' became the staple merchandise. Too long, however, has the public regarded these as the leading industries of the city. Los Angeles has passed from the realm of the potential into the actual. Blocks of fine office buildings, acres studded with beautiful homes, miles of well kept streets and roads, will be shown the visitors. Actual and substantial commerce has been developed and is growing. Far more significant, however, is the spirit of the place. It carries a lesson that we wish each visitor might take home with him. Here is a beautiful and growing city, one that has every feature of the active development that is so dear to Western Americans, a city that has developed pre-eminently the much vaunted 'get together' attitude of public mind, and yet it is one which the people actually rule. Primary elections, the initiative

and referendum, the recall—all these may be seen in familiar operation. It is a place where the citizens take active and intelligent interest in municipal affairs and interpret broadly the functions of government. The great aqueduct, bringing water 250 miles, is being built by the City, largely on force account, and the work is being done as efficiently and as cleanly as any ever undertaken by an American municipality or private corporation. Los Angeles values efficient service in engineering and in business, and secures for itself as good men as serve the railways, power companies, or other corporations. This spirit of the city, this proof that progress does not spell corruption, that unity does not mean domination by corporations, is the finest thing Los Angeles has to offer her guests.

EXAMINATIONS will be held October 15 by the United States Civil Service Commission for the position of 'foreman of mine rescue station,' to which place a number of appointments will be made this fall. In judging the applicants, physical ability will be rated at 40 points, and training and experience at 60. The practical character of the examination is indicated by the announcement that "applicants should have had experience as fire boss, mine foreman, or inspector in coal mining. They should be thoroughly experienced in underground work, capable of finding their way in the darkness of mines with which they have had no previous familiarity, and should have the courage, skill, and physical endurance required in directing rescue operations underground after mine explosions." The pay is set at $1080 to $1500 per annum. All this hardly tallies with the fears of those who thought the purpose of creating the Bureau was 'to provide easy political jobs for highly estimable gentlemen.'

Field of the Mining Congress

The thirteenth session of the American Mining Congress, about to assemble at Los Angeles, is like to mark a turning point in the history of that organization. To many it seems that the chief object of the Congress has been accomplished and that it would be better to adjourn *sine die* than to linger on to a neglected old age. No one can gainsay that forcing the establishment of the United States Bureau of Mines was a substantial achievement on the part of the American Mining Congress. Originally the demand was for the creation of a Federal Department of Mines with a cabinet officer at its head. It was felt that nothing short of that would correspond properly with the importance of the mining industry, and that no less influential an official would be able to obtain for mining and metallurgy the recognition and assistance necessary to their proper growth. The time, however, for the creation of such a Department, if it ever existed, passed. The multiplication of Departments brought confusion rather than order in Government affairs, and the increased power and dignity accruing to the great Bureaus, whose heads remain through administration after administration instead of passing on with each change in the balance of political power, lead to revision of program. A Federal Bureau was asked instead of a Department, and at last the Bureau has been created, a satisfactory Director appointed, and adequate funds for beginning the work have been appropriated. There are those who hold that the purpose of the Congress has been accomplished and that further maintenance of the organization would be futile, answering artificial rather than real needs.

Creation of the United States Mining Bureau, however, was ever but one of the purposes of the Congress. The Bureau was demanded as a means to an end, rather than as the end itself. The real object is the benefiting of the mining industries. To this end the Congress endeavors to promote discussion among mining men of all problems of a public character relative to the industry; to determine what shall be the attitude of the States and of the United States toward mining in all its branches; to crystallize opinion among mining men; and to formulate demands when demands are proper. Establishment of a Bureau at Washington is but an incident. The Bureau must be supported and must be kept up to its work. Criticism, both friendly and at times adverse, of it and of other Federal Bureaus, will doubtless be needed. It is well to remember that ours is a government by public opinion, and since official government, both of the States and the Nation, touches mining at many points, it is important that no agency for creating sound public opinion be neglected. Mining, however, is diverse. Between stoping lead ore and petroleum production, between smelting gold and mining coal, there seems at first to be but little common ground. All, none the less, have relations to freight rates, and, in the Western States, all are vitally interested in questions relating to public lands. All mining and smelting industries have some relation to Government inspection and all have interest in seeing that it be conducted honestly and efficiently—with due regard to the safety of the men and yet not so as to unnecessarily restrict mining operations. These are but a few of the common points. A vigorous and sound public opinion may well be a prime agency in securing substantial justice coupled with that active development which betokens a sound condition of industry. In affording a forum for discussion, a meeting place where acquaintance takes off the edge from controversy, a vigilant and effective means of publicity, the Mining Congress may well serve a useful purpose indefinitely. If though, it retain the fealty of men of such varied interests it must necessarily adopt a broadly tolerant attitude. Its work must be largely educational, and its resolutions must depend for their force on the intelligent conviction back of them, rather than on artificially obtained majorities. Indeed the resolution should be but the minor element. The discussion that leads to agreement is all important. Concerning many of the questions that will be up this year it may well prove impossible to come to any but a forced agreement and the Congress will do better to thresh out these matters in discussion, to make possible the delimitation of the field within which there is substantial agreement as contrasted with matter concerning which there is as

yet no consensus of opinion, than to force a seeming but false unanimity. It is better to go but a short distance than to travel the wrong road. If the Congress do the things here outlined it will find ample field for its energies and the meeting of this year will mark a step toward larger usefulness rather than an abandonment of its field.

Conservation and Mineral Lands

New times bring new issues and new duties. The American Mining Congress, meeting at Los Angeles next week, will be called upon to discuss and to help solve a whole range of problems that have suddenly become vital. Conservation of natural resources is old, but many of the problems connected with it are new to the Nation and to many of the people most directly concerned. No phases of the matter are more complex than are those relating to minerals and mineral land. The water in the streams will continue to flow, lands once cut over may be reforested, and within limits worn-out soils may be restored to fertility; but coal once burned can not be recovered, oil drawn from the earth is not to be drawn again, and ore that has been mined and smelted can no more be counted in ore reserves. If any have a vital interest in conservation it is the miner and, appropriately, the problems of conservation will occupy large place on the program at Los Angeles.

The Conservation Congress that met September 5 to 9 at St. Paul, was a most important gathering. It included representative men from all parts of the country. The addresses were weighty and the debates informing. The enthusiastic call to arms by Mr. Roosevelt and the calm judicial treatment of the subject by Mr. Taft were notable features of the meeting. Fundamentally the same thing was said by both men. The difference in manner reflected little in point of view, and the Congress adopted practically the program they enumerated. Despite these excellent features there is a strong undercurrent of dissatisfaction with the result. It is true that effective conservation involves problems of political economy as well as of science and technology, and that changes in governmental procedure are made through political action. It is apparent that the 'Insurgents' captured the Conservation Congress and that if the program adopted at St. Paul be followed, conservation and 'Insurgency' will become almost synonymous. While appreciating fully the importance of aggressive political leadership in order to accomplish correct solution of certain conservation problems and while personally sympathizing fully with the 'Insurgent' movement, we would not have it forgotten that conservation is a need of all time. Wise use of our resources is as vital to one part of our people as another and a close political alliance has its perils as well as its merits. At St. Paul, mining and its problems were all but unrepresented. Only one speaker, Mr. T. L. Lewis, president of the United Mine Workers of America, was advertised to speak on a distinctively mining topic and he was unable to be present. There is a widespread feeling that many of the peculiar problems of the West, especially those relating to mineral lands, were handled by doctrinaires. They may, or may not, have been well handled; the solution proposed, a general leasing system, may well be the wisest; but the fact remains that the action of the convention was not that of the people most directly concerned. At Los Angeles there will be opportunity for these people to be heard, to criticise if they will, and to justify their criticism if they can. For our own part, without wishing to be dogmatic, we are prepared to endorse some form of leasing as applied to coal, oil, and phosphate lands, and we believe that whatever may prove wise in the future, for the present the public lands in the West should remain under Federal control. In taking this ground we are not unaware of the difficulties in the way of a simple and effective leasing system; we fully recognize the advantages of stimulating individual initiative by giving every citizen a freehold; we believe use is as important as conservation; and we recognize the justice of the argument that the resources of the West should belong to the West, as well as the desirability of developing good State governments by placing responsibilities on the shoulders of the citizens of the States.

The vital problem of the present is to keep the way clear for the future. This is possible under a leasing system. If a mistake be made new leases can be granted on different terms as the old expire. If the whole system prove cumbersome and unwise, it can be swept away and leases converted into fees. The reverse is not true; and therein lies the sound reason back of present adoption of the leasing system. It would be idle to contend that a completely satisfactory form of lease may be devised at once, the system will not free us from difficulties, but it will save the future and will permit close approximation to the needs of the times as conditions change. As to the matter of State versus Federal control, there are sound arguments on both sides. Unquestionably many of the problems of conservation are local, but it is equally true that many are inter-state in character. With the present doubt as to division of authority it is not well to give up a possible vantage point until fully assured as to results. Regardless, however, of theoretical arguments as to proper future division of authority and responsibility, there is a practical point involved. The East and the Middle West are not favorable to any plan of turning over the public lands to the States. Politically they control the situation so that the matter is, for the present, removed from the realm of practical policy. The truth is, and it may as well be faced, that the political conscience of the Nation as a whole is more fully alive to the situation than is that of the people in the Western States. It is also true that it is less expensive to corrupt a State government than to dominate Congress or a Washington department and this is unfortunately important. National legislation and administration are watched more closely and by more people, and are cleaner than is government in at least some of the States. So long as this remain true sound public opinion will favor National rather than State control.

Judith Basin, Montana

STAFF CORRESPONDENCE

Judith Basin embraces that portion of Fergus county, Montana, which is drained by Judith river and its tributaries, comprising nearly one-half the area of the county. While the greater part of this is occupied by wheat growers and live stock men, it has a gold-mining industry, the proceeds of which place Fergus county in the lead among the counties of Montana as regards gold production. The principal supply of this metal comes from the mines which are situated in the North Moccasin and Judith mountains, these being detached ranges on the east side of the Judith river. Kendall is the principal mining town of the North Moccasin, and is twenty miles north of Lewistown. In this range are the Kendall, Barnes-King, and Santiago mines. Maiden and Gilt Edge are mining towns, six miles apart, in the Judith range, and are twenty and fifteen miles, respectively, northeasterly from Lewistown. Maiden is one of the oldest mining camps in the county and has such mines as the Cumberland, Spotted Horse, McGinnis, and New Year, while at Gilt Edge is the Gold Reef mine. The Chicago, Milwaukee & Puget Sound Railway Co. owns the railroad from Harlowton, on its main line, to Lewistown, a distance of sixty-five miles, and this branch is being extended northerly to the Missouri river, the route coming within four miles of Kendall. The Utica sapphire mines, noted for the high quality of their product, are situated in the southwestern part of the basin country. The earliest discovery of this region by white men was made by the Lewis & Clark expedition in 1805, when the name it now bears was given to Judith river.

Not much ore is shipped from the Judith basin, as it is generally highly silicious, free from refractory elements, and amenable to successful treatment by cyanidation. Plants of this character are at present in operation at the Kendall, Cumberland, and Gold Reef, and the practice consists of coarse-crushing and direct leaching in vats by the simplest methods, with no separation of sand from slime. The Cumberland mine is owned by James Breen, of Spokane, and his associates, who erected a mill of 100 tons capacity and set it in operation last May. The first ore milled consisted of 2100 tons of dump material that had accumulated; this ran $11.08 per ton. Since that was finished the mill has been operated on ore from the mine. During the first two weeks of August the mill heads showed $12 per ton, the tailing 66c.; the cost of milling was 65c. per ton; cyanide consumption ¼ lb. per ton; lime, 3 lb.; zinc, ½ lb. The aim is now to get mining and milling costs on the basis of $2.50 per ton; and on the results of thoroughly sampling the ore exposed in the mine, it is estimated that it will average not less than $8 per ton. The ore is reduced to ¼-in. size and is given a 5-days' treatment, the extraction being about 93%. It is being arranged to lengthen the period of leaching to six days, and possibly increase the percentage of extraction. The ore consists of oxidized porphyry and cherty limestone, carrying gold in very finely divided free particles, and in the form of rusty gold that may have resulted from the oxidation of a telluride. In the meantime additional rolls, elevators, and leaching vats are being installed to double the capacity of the mill; and a change from steam to electric power is being made, the plan being to purchase electric power from a local company. The cyanide work heretofore in charge of H. C. Coolidge, is now in control of J. H. McCormack. Mr. Coolidge has been transferred to Mr. Breen's property near Helena. As to the mine, it may be stated briefly that it is situated on the north end of a contact vein that occurs between limestone and porphyry. It was opened ten years ago by Peter Rosso and others, who operated with good success on the high-grade parts of the orebody. In 1909, prior to the sale of the property to Breen and associates, Rosso shipped five carloads of ore to the smelter that netted him $25,000. Most of this rich ore was taken from an intermediate level 80 ft. below the surface. The mine was first opened by a vertical shaft from the surface to a depth of 183 ft., from which three levels were driven; later, a 200-ft. adit was driven to the base of the shaft from the side of the hill. This is called the mill level, as trackage from it leads to the feed floor of the mill. The workings show a body of oxidized ore over 100 ft. wide on each level. On No. 3 level is a stoped-out chamber 72 ft. long, 45 ft. wide, and 32 ft. high, and it does not appear that either wall was cut. On No. 2 level, 86 ft. above No. 3, there is a cross-cut about 100 ft. in ore. Work is in progress on the strike of the vein at the mill level and on the one above it. Albert I. Goodell, formerly superintendent of the Northport smelter, is at the Cumberland as the representative of Mr. Breen.

The old Spotted Horse mine, now under option to James Breen, is adjoining the Cumberland on the south, and is on the same contact. Since taking the option Mr. Breen has had the 440-ft. shaft retimbered, the levels cleaned out and put in order, and the ore exposed has been sampled. On the dump there are estimated to be 30,000 tons of ore which may average $7.50 per ton. It is possible that the ore on the dump and some of that in the mine may be treated at the Cumberland mill. The Spotted Horse ore, however, contains some base material, and its treatment would be more difficult than that of the Cumberland. It is claimed the Spotted Horse, operating from 1893 to 1902, produced ore of the value of $3,000,000, and that the recovery of the gold and silver was by pan-amalgamation. The milling plant was destroyed by fire eight years ago. The owning company, which gave the option, is the St. Paul & Montana Mining Company.

Still farther south on the contact is the McGinnis mine, owned by Conrad-Stanford Co., of Helena. In earlier days it was a good producer and supplied a mill. It is now being operated by lessees who employ a small force and make regular shipments of sorted ore to a smelter at Butte. The last car of ore shipped had a gross value of $70 per ton. The McGinnis ore contains a good deal of visible free

gold, associated with considerable sulphide material.

The Gold Reef mine and mill, at Gilt Edge, belong to John A. Drake, of New York, and are under lease to W. W. Badger, T. O. Caldwell, E. W. Cooper, and R. F. Turnbull, who are now on the fourth year of the term of lease. Drake purchased the property from the Great Northern Development Co. in 1903, the milling having been built previous to this. The orebody here occurs in the form of a nearly flat vein between a porphyry hanging wall and a limestone

Kendall, Montana, in the Judith Basin.

Gold Reef Mine, Gilt Edge, Montana.

foot-wall. It is opened by one principal adit level that has been driven 2400 ft. partly in the foot-wall and partly in the orebody. Numerous raises are made from the adit level into the stoping ground. One stope above this level shows 300-ft. width of ore and a thickness of 98 ft. A large tonnage is mined from open-cuts above the main haulage level. The strike of the ore zone is north-south, and the workings extend a mile thereon. The main zone is divided into three separate sections by the erosion along two gulches. The gangue is made up of porphyry and altered limestone and will hardly average $2 per ton. Some months it has run as low as $1.60. The total mining and milling costs seldom run higher than $1.10 per ton of ore milled, the ore treated averaging 225 tons per day. The gold occurs in fine particles, but is non-amalgamable. The mill is equipped with a No. 5 Gates crusher, 2 sets of rolls, each 36 by 24 in., six leaching vats—four of 165 tons capacity and two of 240 tons. The ore comes to the vats crushed to ¼ in. and less, the leaching period being 72 hours. This is an example of economical operation on a narrow margin. The small profit each month could easily be wiped out by a little extravaganee.

The Kendall mine belongs to the Kendall Gold Mining Co., of which H. H. Lang is superintendent. It is situated at Kendall at an elevation of 5000 ft. Electric power is used and this is generated on Warm Spring creek, five miles distant and 1200 ft. below the mine. The water all comes from a large warm spring 100 ft. in diameter, and flows at the rate of 8000 cu. ft. per minute. At present 400 hp. is used at the mine. Much of the mining to date has been done by open-cuts. In underground workings the timbering is with square-sets which are filled. There is about 8% moisture in the ore, just enough to keep it from being dusty. The ore is ideal to treat with cyanide, yielding 87% with low strength solution. It is crushed so as to pass through a screen having one-half inch square opening, is carried by belt conveyor to steel vats, and covered with strong solution (1½ lb. of 125% NaCy to one ton of water), for three days, followed by the weaker solution (1-lb. strength) for two days, and finally one day of washing with water. In treating 693.972 tons of ore averaging $5.75, the tailing assayed $0.734; an extraction of 87%. The costs for the above tonnage were as follows: development, $0.481; mining, $1.125; milling, $0.517; office, insurance, taxes, interest, exchange, and legal expense, $0.238; miscellaneous, $0.261; total operating expenses, $2.622.

BORAX IN CALIFORNIA

The production of borax in the United States is at present confined to two California mines, the Lila C of the Pacific Coast Borax Co., situated in the foothills of the Funeral range of mountains, and the Lang mine of the Sterling Borax Co., about fifty miles north of Los Angeles. The monthly production of these two mines is between 3000 and 3500 tons of crude mineral.

The Lang mine of the Sterling company is situated at Lang, Los Angeles county, and is connected with the main line of the Southern Pacific by a narrow-gauge railroad five miles in length. The mineral occurs in a vein from 6 to 16 ft. wide, between two porphyry dikes about 100 ft. apart. The dip of the vein is about 70°, and both hanging and foot-wall are composed of a slaty clay. Back of this clay is a hard sandstone that holds well enough to permit of mining from open stopes. The deposit has been developed on the surface for about 1½ miles and is opened underground by two shafts, between 250 and 300 ft. deep, and about one mile of workings. The mineral, which is chiefly colemanite, occurs in shoots about 1000 ft. long, and has the following approximate composition as it is mined: anhydrous boric acid (B_2O_3), 36%; lime, 35; silica, 10; magnesia, 1 to 5; balance, water. Among other borates, the mineral pandermite is found here. This is a white chalky material, high in boric acid, but so refractory that it cannot be handled profitably at the present price of the mineral. From 60 to 70 men are being employed at the Lang mine and about 1500 tons of mineral per month are being shipped to the Chicago and Pittsburg refineries of the Sterling company.

The Lila C mine of the Pacific Coast Borax Co. lies about eighteen miles northwest of Greenwater and eight miles southwest of Death Valley Junction, from which point it is connected by a spur with the Tonopah & Tidewater railroad. Here there is a deposit of calcium borate from 3 to 18 ft. thick and dipping about 45° easterly. The deposit has been opened by adit levels, surface development extending for over a mile. The production here is slightly larger than at Lang, but the grade of the mineral is not quite so high. Before shipment to Eastern refineries the material is calcined.

Although it is impossible to secure any definite data on costs, there can be no doubt but that both of these mines are operating at a loss. In general it may be said that in order to pay a reasonable interest on the investment the price of the finished product must be in the neighborhood of 5c. per lb. For the past two years the price has been below 4c. and for the last few months the quotations have been near 3½c. The low price of borax is the result of a fight for the control of the industry that has been in progress for more than two years. At present the Pacific Coast and Sterling companies are the only contestants and there is nothing in sight to indicate the end of the struggle. The owner of a small borax property has no possible chance, his only hope being to sell at a sacrifice to one of the above-named companies.

In addition to its use in medicine and for various household purposes, borax is employed in the manufacture of various grades of glass, porcelain-coated ironware, pigments, and preservatives for canned goods. To a certain extent borate of ammonia renders cotton goods uninflamable. Borate of chromium is used in a green pigment for printing on calico. Borax is used also in assaying and in soldering, brazing, and welding metals. This use is due to its property of dissolving metallic oxides when heated to a high temperature.

Metallurgical Practice in Western Australia

By A. E. Drucker

There are at least nine noteworthy gold-producers at Kalgoorlie—the Golden Horseshoe, Great Boulder, Ivanhoe, Perseverance, Kalgurli, Associated, Lake View, Oroya Brownhill, and South Kalgurli. Three

The Golden Mile, Kalgoorlie.

of these crush their ore in Krupp ball-mills, one with Griffin mills, one with both ball and Griffin mills, and the remaining four with stamps. The two main methods of ore treatment used at Kalgoorlie may be classified as follows: (1) Dry-crushing, all roasting, all-sliming in pans, and amalgamation, cyanide agitation of slime, and filter-pressing (the Great Boulder uses the Ridgway filter). (2) Wet-crushing in cyanide, classifying, concentrating, all-sliming in tube-mills, raw slime bromo-cyanide agitation (concentrate-roasting, amalgamation and all-sliming in pans, cyanide agitation), filter-pressing.

Wet-Crushing with Stamps.—Of the various Kalgoorlie mines mentioned above, the Lake View, Oroya Brownhill, and the new 100-stamp mill at the Horseshoe are all-sliming. The coarse sand is ground fine in pans, and then slimed in tube-mills.

Golden Horseshoe Gold Mine.

(The Horseshoe employs tube-mills only for this purpose.) The Ivanhoe and the old 50-stamp mill at the Horseshoe treat the sand after a previous grinding in pans, by percolation, the slime being treated raw by bromo-cyanide agitation and filter-pressing. All these plants are wet-crushing in cyanide solution and have done away with the old plate-amalgama-

important dry-crushing plants of Kalgoorlie are the Great Boulder, Perseverance, Associated, Kalgurli, and South Kalgurli. These employ, mainly, ball-mills which are in high favor, and although they do not produce as fine a discharge, they are more economical in supervision, repairs, and power. The grinding-pan has played an important part in the metallurgical practice of Kalgoorlie. It has been used mainly with the all-roasting process in regrinding sand and amalgamating coarse gold. The gold won from this source varies from 25 to 35% of the total yield.

Since the discovery of gold in Western Australia, $390,374,528 worth has been produced up to the end of 1908, of which the Kalgoorlie field has contributed 10,006,627 fine ounces, valued at $206,836,980. The

total dividends for the State to the end of 1908 amount to $92,164,529 of which Kalgoorlie paid $73,163,928. During the past year (1908) the Kalgoorlie mines paid in dividends $5,925,991.

Since the production of gold began in 1903, it has been steadily falling year after year. The average yearly decrease has been for the past six years 61,045 fine ounces. The average yearly decrease since 1903

for Kalgoorlie district equals 28,687 fine ounces of gold. It may safely be inferred that the general depression due to declining yield of Western Australia will be relieved in a measure by the recent satisfactory developments at Kalgoorlie, Gwalia, and several of the smaller mining districts. Kalgoorlie, like all other noted gold mining districts, has seen its best days, and has now settled down to production of ore of medium grade.

Telluride Gold Ores.—The refractory nature of the Kalgoorlie ores is due largely to the occurrence of the gold in combination with tellurium, forming a compound, $AuTe_2$ or $(Au,Ag)Te_2$, which is represented by the minerals calaverite and sylvanite. There is a difference in the ore at these various mines, due to variations in silica, sulphur content, proportions of telluride to free gold, occurrence of graphite, etc. The ore may be described as an altered greenstone schist containing from 50 to 70% of quartz. The mineral constituents are pyrite, pyrrhotite, and tellurides of gold, silver, and mercury.

Tellurides are widely distributed, and in some mines contribute a large portion of the total gold yield. Mines containing a notable amount of telluride are usually equipped with dry-crushing, all-roasting plants. Where tellurides occur in ores treated in wet-crushing plants, a careful concentration has to be resorted to previous to bromo-cyanide treatment. The concentrate collected is roasted before agitation with ordinary cyanide solution. Ordinary KCN or NaCN solutions are without solvent action on gold in combination with tellurium. Owing

‡ Includes 5118 oz. fine gold from slags, etc.
⊙ Includes 1358 oz. gold from slags and retreating dumps.

to the variations in the ore at the different mines each property had its own metallurgical problem to solve, and hence there is a great diversity of plants and methods. Kalgoorlie had not the opportunity to profit from experiences gained elsewhere in treating similar ores. It can be safely said that this district was the first to successfully solve the mill treatment of gold-telluride ores on a commercial scale.

The following analysis will represent the two different types of ore treated at Kalgoorlie:

	Ivanhoe, Wet-crushing, Bromo-cyaniding. Per cent.	Associated, Dry-crushing, All-roasting. Per cent.

MANGANESE IN THE UNITED STATES

The important and numerous uses of manganese, or of its ores, give practical interest to the many deposits in this country, which are described in detail in a report by E. C. Harder, published by the United States Geological Survey as Bulletin 427.

Manganese is one of the elementary metals, and was long considered a kind of iron. Pliny regarded it as a variety of lodestone, or magnetic iron, and it was not identified as a distinct metal until late in the eighteenth century. The ancient judgment is somewhat justified by the modern classification of manganese among the elements of the iron group, which includes iron, manganese, cobalt, and nickel.

Manganese is not found naturally in the metallic state, but occurs principally as an oxide, silicate, or carbonate. Rhodonite, a beautiful pink manganese silicate, is cut for jewels, and the purple of the amethyst is supposed to be due to the presence of manganese. Minerals containing manganese are widespread, but few are available for use as ores, for most of them contain only small percentages of

The Brownhill, Ivanhoe, and Lake View are all wet-crushing plants, while the Perseverance is dry-crushing, all-roasting. The wet-crushing process gives a net bullion extraction of 86 to 90% at a cost of about $2.30 per ton, while dry-crushing yields 90 to 94% of the gold with a cost of $2.70. It is generally conceded at Kalgoorlie that dry-crushing, all-roasting process has won, and is the most profitable method. However, I think that through increased stamp duty, screen classification, and closer concentration, the wet-crushing process will prove to be the most profitable. In places where fuel and furnace supplies are high, the bromo-cyanide process would show an advantage no doubt. The chemical process requires considerable metallurgical skill and constant attention to the progress of each vat. The alkalinity of the cyanide solutions is important, the best extraction being at about 0.01% to nearly neutral.

the metal. The oxides psilomelane and pyrolusite are the principal ores.

Pyrolusite, which contains about 60% of manganese, was used by the ancient Egyptians in decoloring glass, that is, in making it clear or transparent, for the addition of this mineral to glass sand neutralizes or in some way counteracts the effect of iron, which gives to glass green or other undesired colors. Pyrolusite is still used for this purpose, but ores or alloys of manganese are now more largely used in making alloys with iron, steel, copper, aluminum, and other metals, in making chlorine, bromine, and oxygen, and as a disinfectant, as well as in galvanic batteries and in bleaching, dyeing, and painting.

Spiegeleisen ('mirror iron'), so called from its brilliantly glittering surface, and ferromanganese, both alloys of iron and manganese, are prepared chiefly for use in metallurgy.

New Shaft Sinking Record at Corbin, Montana

By Frank J. Tuck

H. E. Emerson, manager for the Boston & Corbin Copper & Silver Mining Co., has achieved an enviable record for rapid shaft sinking at the company's mine at Corbin, Montana. From June 15 to August 20 a three-compartment shaft was sunk exactly 213 ft.; from the 400-ft. station to a point below the 600. In other words, about 100 ft. per month was made, a record for the district. It is doubtful if a three-compartment shaft of equal size, and under similar conditions, has ever been sunk so rapidly and at the same time so cheaply. The actual total cost for power, labor, timber, and supplies, was only $40.95, and this included a handsome profit check to the men who did the work on contract.

The rock through which the shaft was sunk was a dark hornblende granite, commonly known as Butte granite. The rock section of the shaft measured about 17 by 7 ft., each compartment being 4 by 4½ ft. in the clear. For wall plates and end pieces 10 by 10-in. timbers were used, the dividers being 8 by 10. The sets were spaced 5 ft. centre to centre. Only one compartment was employed for sinking; a second being used for hoisting rock from the two upper development levels; and the third as a pipe and ladderway. A double-drum, electric, geared-hoist, of Wellman-Seaver-Morgan type, with a 100-hp. Crocker-Wheeler motor, handled the cages in both compartments very satisfactorily. A straight-sided sinking bucket of about twelve cubic feet capacity was hung to the cage in the sinking compartment, and was used for hoisting water as well as broken rock. The flow of water was not excessive, about thirty-five buckets per day being hoisted.

Two Sullivan UB, 2½-in. machines, with air at 80 lb. pressure, were used, and from 18 to 25 holes were drilled per round. This included 6 cut-holes which were blasted previous to the others. The holes were from 5 to 7 ft. deep, usually averaging about 6 ft. The firing was done by caps and waterproof fuse, and there was no trouble with the electric hoist when hoisting men before blasting. Forty per cent gelatine dynamite was used, and with a regular charge, the ordinary 10 by 10 blasting timbers afforded satisfactory protection to the lower sets. It is doubtful if this would have been the case if batteries had been used for firing. Station sets were put in at the 500 and 600-ft. levels.

The contract for sinking the shaft was awarded to three miners who agreed to furnish their own supplies and do the drilling, blasting, shoveling, and timbering. Each of these miners took charge of an eight-hour shift and had three other shaft men working with him. Co-operation and hard work seem to have been the key-note of their success. No miners ever worked with more vim, intelligence, and enthusiasm. The timbering was perfect, the whole 213 ft. being exactly plumb. While the men were paid $4 per day for their labor, their profit check netted them a snug sum, and there is no doubt that the company was given handsome returns.

The cost per foot of shaft was as follows:

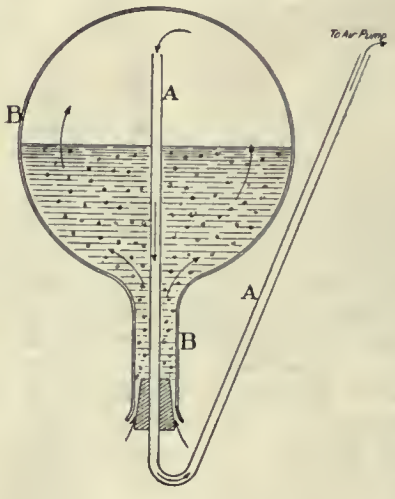
Labor, cost per foot	$32.76
Lumber, per foot	4.58
Supplies, powder, caps, fuse, candles	2.04
Power	1.57
Total	$40.95

Besides the power and timber, the company furnished top-men, engineers, blacksmiths, and carpenters. One carpenter succeeded in keeping the shaftmen supplied with timbers, and the blacksmith and helper supplied the whole mine with sharpened steel. Three other machine drills were in use in the mine besides those in the shaft. The wages paid were as follows: Engineers, $4; shaftmen, $4; blacksmith, $4; blacksmith helper, $3.50; carpenter, $4.50; top-men, $3.50.

LABORATORY AGITATION APPARATUS

By George A. James

The apparatus illustrated below is designed to furnish a simple method of duplicating the operation of the Pachuca agitator for laboratory experimental work. In the figure A is a tube bent, as there shown and of such length that it will reach quite close to the bottom of flask, B, when introduced through the loose fitting cork, and which extends about the same length outside the flask. I select for the cork one that is porous, or, if necessary, sear the cork so that air can pass between it and the neck of the flask, but do not leave sufficient space to let the contents of the flask pass out when the same is inverted. The material for treatment is introduced and the cork is entered loosely enough to permit the passage of air, but tight enough not to permit it to fall out under the weight of the contents of the flask. Tube A is then connected up with a Bunsen, or Richardson suction pump, and the flask, with contents, inverted. It will be seen that this produces a partial vacuum, which in turn draws the air around, and through the cork, and this, by being passed through the pulp, gives any degree of agitation and aeration.



Where I have a number of tests to run simultaneously, I use a tight fitting cork, and instead of the air passing around it, a bent tube which just enters above the cork, and which extends above the level of pulp, outside of the flask is substituted. This can be connected to another apparatus, the air passing from one flask to the other in sequence.

Rand Mine Returns and the Fathomage System

By W. W. Mein

***Abuse of 'Ton Milled' Unit.**—In his recent address, H. F. Marriott drew an alarming picture of the abuses of ordinary methods, scarcely gratifying to men in any positions of authority, responsible for the control of Rand mining in recent years. Although Mr. Marriott is but a moderate supporter of 'wholesale' mining, his imputations of incompetence or dishonesty against Rand managers are certainly conducted on wholesale principles, without much thought of selection. He asserts that "all other economic considerations have bowed before the overwhelming flood of reducing costs per ton milled." If all economic considerations had been swept aside in favor of low costs per ton, surface quarrying on the outcrop mines would alone be seen today and there would be no tube-mills to effect such a costly refinement as high extraction. According to the accusation, responsible control has been too lax, and yet the new system of mine returns is proclaimed as the 'emancipation' of the mine manager. Mr. Marriott argues that the 'ton milled' is objectionable in that it is "whatever the manager chooses to make it." This statement suggests confusion of ideas, for the ton is an absolute unit. The grade of the ton, certainly, is whatever an irresponsible and uncontrolled manager might choose to make it (with limits only on the side of richness), but the ton or an equivalent in cubic measure does not cease to be a definite unit of equipment capacity. Neither the ton milled, nor the fathom stoped, nor the ounce of gold won, however, can be employed as a general unit to produce a summarized tabular statement automatically enforcing those desired conditions—careful mining, close attention to value of the ore, and systematic investigation of the relation between results and estimates.

Low Working Costs.—Mr. Marriott has cited a supposedly typical instance of low working-cost abuses that provides an excellent means of concentrating discussion. The assumption is that there is a ton of 30s. ore, costing 20s. to treat, and therefore yielding 10s. profit. In the hanging wall there is another ton of 15s. ore which "comes into the stope for nothing." The case against low costs is stated as follows: "The reduction of working cost is 2s. 6d. over the whole rock extracted. In place of one ton at 20s., there are two tons at 17s. 6d., which equals 35s. working cost; the gold extracted is 45s.; the profit is 10s.; the same as before over the same area. The limit of advantage in this practice is that the 15s. coming in balances the 15s. going out, and the profitable result is *nil*." A faulty conclusion is reached owing to the employment of abnormal figures. With 20s. cost for the richer ton, the additional ton, costing nothing to break, could not cost a further 15s. under any rational apportionment of expenditure. The 20s. cost of the first ton is presumably made up roughly of the following costs per ton milled: stoping, 6s.; shoveling and tramming, 2s. 6d.; hoisting, pumping, etc., 2s. 6d.; surface, 5s.; development, 2s. 6d.; general and head office, 1s. 6d.; total, 20s. The extra ton, by hypothesis, bears no stoping cost (6s.) and its development (2s. 6d.) has already been paid for. Shoveling costs will be lower per ton in the wider stope, and tramming cheaper owing to the greater concentration of labor. These charges will then be about 2s. per ton, and hoisting, etc., about the same figure (2s). General and head office, pumping, and all fixed charges are included in the 20s. expenditure on the lower ton. The extra cost for the upper ton is therefore 8s., or at most 10s., and the extra profit 5s. to 7s., with the profit on the lower ton increased to 11s. The total profit is thus 16s. to 18s. for two tons, in place of 10s. where one was excluded. Yet Mr. Marriott estimates that the extra ton would only be treated for the "craze of keeping a full mill going." This reference to idle stamps clearly shows that he does not wish it to be estimated that another ton of 30s. ore could be treated in place of the 15s. rock left in the hanging. Such an assumption would promptly raise the question of increased stamping capacity.

Rich Ground Deferred by Mining Poor.—When the question of the displacement of richer ground is introduced, the viewpoint changes. We may, for sake of lucidity, still assume the condition of a stope width worth 30s., with an equal width above to 15s. I have already indicated the probable loss through leaving the 15s. ore, when stamps are idle and when no richer ore can be assumed to be displaced thereby. When all the stamps are or could be employed on 30s. rock, with 10s. profit, the often difficult question arises whether it would not pay to leave the upper ton so as to increase the present worth of future returns. The question involves a great deal of judgment as to the higher expense involved in returning to old workings and as to the actual loss of ground it may not pay to recover at all. The relative value of the two grades is further of critical importance. Where a single ton yields 10s. profit and the two tons mined simultaneously 16s. to 18s. profit, it would certainly pay best, under typical conditions and where, as assumed, the 30s. and 15s. ore can be stoped conveniently together in one stope width, to exhaust the area and abandon it. The exclusion or inclusion of the upper bands and the consequent reduction of working cost and grade per ton milled are questions bringing us back to Mr. Marriott's quotation of European shareholders, who are said to argue that the 2s. reduction in cost is no good to them, because they do not get the extra 2s. profit. While the yield per ton has fallen correspondingly with profit and cost per ton on many mines, there has generally been an increase in tonnage and total profit, as recognized in a strangely ironical reference by Mr. Marriott to "magnificent outputs," as though such things in gold mining were cause for shame. The increase of mill tonnage has been coincident with a fall in grade, for the reason

*Abstract from advance proofs, subject to revision, of an article presented to the Institution of Mining and Metallurgy.

that, generally speaking, it has been the considerations of the lower-grade ore that has justified the augmented equipment.

Mr. Marriott apparently wishes to combine the selective grade of the small equipment with the large tonnage of the big. It is by losing sight of the fact that the capacity of plant is governed by the claim area and the probable tonnage of ore per claim (controlled by a pay-limit dependent in large degree upon scale of operations) that the opponents of low working costs per ton milled fall into error. Again, considering the case of the mine with a 3-ft. stoping width at 30s. and an additional 3 ft. of 15s. ore in the hanging, this condition would warrant in practice the erection of equipment from 50 to 100% greater, if the two grades were mined coincidently, than if the richer were stoped alone and the poorer left indefinitely for subsequent extraction. In the first case every foot of development opens twice as much ore for early milling requirements as in the latter.

Here arises a clear-cut issue between the low-cost big-scale practice of mining and the 'new policy.' The selective policy would involve operations on a scale indicated by the 30s. ore, leaving the 15s. ore in the hanging, either to cave or else to be supported by filling, for recovery at a considerable risk and expense when the richer ore had been exhausted. The wholesale policy would involve the treatment of the two grades in conjunction; the greater tonnage of assured profitable ore warranting the erection of additional stamps or tube-mills to meet the maximum profit requirements of the mine. When narrow widths and high costs prevail, the uncertainty of being able to establish later the low costs essential for the low-grade ore to be ranked as a profitable asset, prohibits the inclusion of the deferred ground as a factor in the calculations of the scale of treatment.

The issue is most clearly indicated by the following simple example, still utilizing Mr. Marriott's grade figures. A mine contains 10,000,000 tons of mill ore worth 30s. and 10,000,000 tons of associated 15s. ore. Scheme (1) taking the reefs singly, the mine is equipped with plant treating 500,000 tons per annum; (2) taking the two grades in a single stoping width, the greater security of payable tonnage would warrant an increase of at least 50% or 250,000 tons in annual capacity. This would allow one ton of the poorer ore to be mined to two tons of the richer. In this latter case the yield per ton is 25s. and the working cost (as indicated previously) would be made up as follows: 1 ton of 30s. ore at 20s.; combined stope width, 1 ton of 30s. ore at 19s., 1 ton of 15s. ore at 9s. This is equivalent to three tons averaging 16s. per ton, giving a profit of 9s. per ton as against 10s. The small difference in profit per ton in this case, following logically Mr. Marriott's figures, reveals strikingly the common fallacy that because certain ore in a mine—as in the hanging or foot-wall—contains less gold than average working costs, it is making no profit. Its own cost may be well below the average, apart from its influence in bearing a share of the standing charges. (For simplicity, Profits Tax is omitted from all comparisons.)

RESULTS UNDER SCHEME 1

500,000 tons per annum at 10s. profit	£250,000
Life on rich ore	20 years
Factor at 7% interest and 3% redemption	9.32697
Present worth	£2,331,743

At the end of this period there would remain 10,000,000 tons averaging 15s. per ton in caved or filled stopes, the recoverable portion of which would be doubtful. There would be no development costs, this expense having been wastefully borne during the previous 20 years. Assume favorably that all is recovered at a cost of 12s. per ton or 3s. profit, as follows.

500,000 tons per annum at 3s. per ton	£75,000
Factors—20 years life deferred 20 years	2.68331
Present worth	£201,248
Add first period	£2,331,743
Total	£2,532,991

RESULTS UNDER SCHEME 2

750,000 tons per annum at 9s. per ton	£337,500
Life on combined ore 20 years, factor 9.32697	£3,147,852
There will remain 5,000,000 tons at about 3s. profit, producing at 750,000 tons per annum	£112,500
Life 6.667 years, deferred 20 years, factor	1.19739
Present worth	£134,706
Add first period	£3,147,852
Total	£3,282,558

The difference in favor of Scheme 2, is £750,000 or 29%; approximately half a million after allowing for extra capital expenditure involved in erection of the additional plant. It would, of course, be unreasonable to argue that a better result might be obtained by working only the richer ore at 750,000 tons per annum and deferring the poorer; for we start off with the assumption that the 30s. ore is treated on the maximum scale of 500,000 tons per annum.

This is a theoretical case founded on the typical figures advanced by Mr. Marriott. Summarizing the results of the Central Administration group for 1906 and 1908 (the period of striving after low costs, big tonnages, and "magnificent outputs") yields the following comparison:

	1906.		1908.			
	s.	d.	s.	d.	s.	d.
Cost per ton milled	22	5	17	5	Decrease 5	0
Yield per ton milled	38	10	37	5	Decrease 1	5
Profit per ton milled	16	5	20	0	Increase 3	7

These figures show a total increase in profit of £730,000, or exactly 50%. This must surely be considered a beneficial result of the "craze for keeping the full mill going" and greedily asking for "more stamps."

Quarterly Reports on the Fathom System.—Under the new system of compiling mine returns, the test of good management and policy will appear in the progress of quarterly records of "profit per fathom." This blind striving for "maximum profit per fathom" involves serious dangers. A high return per fathom might be obtained for a period by selection of a character that is dearly paid for in the course of time. It might be effected most easily

by the picking of the mine, resulting in the disorganization of subsequent operations, a misleading representation of the profit-making capacity of the ore reserves and a loss of the confidence of the investing world. An effort is made in the new returns to prove too much in condensed form, and the systematization of Rand records must reach miraculous heights before the "proof of good management" can be revealed in a figure in part based on the manager's judgment, and capable of substantial alteration "at the stroke of a pen." It may of course be contended that these new returns will have to be checked by the controlling interests, but if these controls and managements were incapable of exercising intelligent supervision under the ordinary systems, giving a far more detailed and rational view of conditions, how can they be trusted to handle capably a new system that is necessarily based on the old for its proper compilation, however much that dependence on the tonnage unit is concealed?

Maintaining Development.—"Note No. 1. Average percentage of payable to total ore based on the working results obtained during the past year. (To be utilized in comparing fathomage developed and stoped.) As a general average for the whole mine the limit of payability is governed by column 11.

"Col. 1. Areas developed on plane of reef in square feet; South Reef; Main Reef; Main Reef Leader.

"Col. 1a. Total area in square fathoms.

"Col. 2. Areas stoped out on plane of reef in square feet; South Reef; Main Reef; Main Reef Leader.

"Col. 2a. Total area in square fathoms."

These columns are compiled in parallel in order to demonstrate the relation of ore developed and stoped on the new basis, and to show readily, in conjunction with the past year's estimate of percentage of payability, whether development is being maintained. Here, immediately, appears a serious fallacy, due to the attempted evasion of the stope-width factor. Mr. Marriott has stated in explanation: "Column 1 or areas developed should total at the end of each year more than the areas stoped out in column 2 by the percentage required under the payability estimate. Otherwise the mine will be falling behind in its development." This is a delusion and provides a good instance of the deceptiveness of this method of investigation. However much Mr. Marriott may try to eliminate the influence of variations in reef width, he is baffled by hard facts. The fallacy of the argument may be shown by the following simple figures for a year: mill-capacity 80,000 tons per month; percentage payable 100; area developed 120,000 fathoms (3 ft. stope width); area stoped 100,000 fathoms (5 ft. stope width). According to Mr. Marriott this mine must be increasing its payable reserve, owing to the excess fathomage developed. In point of fact, only 1,080,000 minable tons were developed as against 1,500,000 tons mined, and the ore reserves fell back by nearly five months' mill supply. The usual records of tonnage developed per quarter, though always liable to adjustment upon the compilation of ore reserves, therefore give a reliable index as to the maintenance of payable ore reserves, while the new scheme may give a wholly erroneous showing.

Then again, the adoption of the previous year's percentage of payability would represent most culpable laxity. It indicates a spirit of 'emancipation,' certainly, but, as I have mentioned in discussing monthly development records on the tonnage basis, it is preferable to be the slave of reliable sampling averages than merely free from care through wilful ignorance of facts. The figure the manager is to be guided by is the percentage payable of last year's development, which may have been 90%. This year he strikes bad ground and the true percentage payable is only 45. For every 90 fathoms he stopes he will be developing 100 fathoms instead of 200, and create the false impression that there is no falling off in ore reserves. If a mine consistently develops poorer ground, year by year, the manager would always be a year behind in his standards. Further, the percentage payable for the year will be based on all reefs, while the ratios in which they are worked are apt to be changed frequently, creating further discrepancies between the true and represented conditions of relationship between added and exhausted ore.

Column 3. Resultant average stoping widths by actual measurement: South Reef, Main Reef Leader, Main Reef, Total.

Mr. Marriott explains: "The actual stoping widths taken in the wake of mining operations will, in conjunction with figures for areas stoped, enable the true tonnage extracted from the mine to be calculated. Discrepancies with this figure in treatment operations will have to be investigated and corrected."

The only average stoping width obtained by actual measurement is that employed every month by mine surveyors in relation to normal stoping. This figure is carefully compiled under existing systems, already described. It is compared with the width calculated from the tonnage trammed, and investigated if unusual. The figures cannot with reason be extended to the uses involved in Mr. Marriott's return. The ore from development faces, from packs, sweepings, foot-walling, and from those miscellaneous sources comprising so important an item, especially in old mines, cannot be given an accurate stope width any more than they can accurately be credited with 'fathomage.' Either a fathomage must be estimated and a stope width deduced therefrom, or else a stoping width estimated (or taken, without rhyme or reason, at the average for normal stopes) and a fathomage deduced. Whichever arbitrary method is adopted, the result is the product of the manager's 'judgment' and at the same time an important factor in the estimation of that figure "by which good management is judged." It may prove good management of figures, but ability in mine management cannot be determined by any such simple means.

Columns 4 to 8. Relation between gold won and reserve values.

The principle of combining the two distinct fac-

tors—discrepancy in ore-reserve estimation and loss of gold in residues—is reprehensible and will not serve to impress shareholders with the efficiency of either department. A perfect agreement between gold won and estimated, after allowance for metallurgical extraction, might be regarded as good work, when in reality due to an underestimation of ore reserves. If, for example, in the estimation of reserves it is calculated that certain bands will be left in the hanging and in actual practice they come into the stope, it is clear that a high percentage of recovery will be shown, owing to the gain of extra gold not recorded in the original figure of block content. A comparison between the gold content estimated for a block and that won is at all times useful, but when the comparison is carried to the pitch suggested by Mr. Marriott it becomes deceptive. Mr. Marriott arrives at a faulty conclusion for the reason that he loses sight of this simple fact that the ore reserves of a mine are made up of a number of blocks at various stages of attack and valued with varying degrees of accuracy. The average value of the reserves is made up of a range of probabilities, from factors of practical certainty down to provisional estimates of comparatively poor foundation. In entering up the estimated value of the block in its original form, before stoping has added its important evidence, a figure that is admittedly provisional is used. The gold won from a single block, as initially valued, may be 70 to 130% of that estimated upon the inadequate information of development, and yet the gold won from total ore reserves, including all the worked and well-proved blocks, only 5% short or in excess. The claim made that the new system will reduce clerical work cannot be admitted. Unfortunately the needless labor and responsibility will fall chiefly on the shoulders of the higher officials—mine manager, secretary, and chief surveyor—whose time would be far better occupied in attending to economically essential matters.

Working Costs.—Broadly, Mr. Marriott divides the costs into two main heads (1) those inside, and (2) those outside the stope. The former are based on actual costs per fathom and are therefore approximately correct, but the latter—representing the greater proportion of the cost of mining—are apportioned in a grotesque fashion. The costs of tramming, hoisting, breaking, milling, etc., are suggested to be distributed on the fathomage basis without reference to tons at all. No mention whatever is made by Mr. Marriott of stoping width or tonnage. Thus all fathoms in the mine, for which costs are segregated to the different blocks with supposed refinement, will be debited with an equal cost for tramming, etc., irrespective of whether that fathom means 27 tons or 9 tons. While one block may be run at a big loss and the other at a big profit, Mr. Marriott's method may represent that each fathom yields the same profit. On the face of it, this is wrong. Mr. Marriott is very strong in his condemnation of mining wide stopes of low-grade for the sake of "magnificent outputs" and low costs. He claims that his "square fathom basis" will show this up and "emancipate" the manager. This throws new light on the nature of the emancipation. Citing specific figures, it is clear that the manager would be treating 12s. ore and appear to be making a profit, while on the old tonnage basis the unpayability of the ground would be evident and the ground would be left.

Column 12. Total distributable profit obtained (6—11a).

This is the soundest column in the whole return, representing a figure that is absolute and important. Unfortunately it is not allowed to stand uncontaminated, for in column 13 its value is dispelled by the application of a fictitious divisor—total fathoms stoped. In reality, this divisor represents the true fathomage of virgin stoping (used freely in the tonnage system of mine returns in its proper applications) plus an addition, according to taste, for development rock, reclaiming, packs, etc. By this column, profit per fathom, "good management will be judged." Consider the position of the manager of a mine with declining grade or of the manager taking over a mine after one of the "emancipated" slaves of economy has been at work for a year. The narrow high-grade blocks have been depleted and to keep any mill running at all, he puts through the lower grade, wide 'reef' which shows as much gold per fathom as the other, but costs twice as much per fathom to treat. This manager may raise the efficiency of every department, per unit of work, may collect the most skilful staff on the Rand, fill his mine with the most competent miners, may eradicate every weak spot in the operation of the mine, and yet he will be doomed under the infallible and merciless tyranny of column 13. He can offer no excuses—the "yield per fathom" has remained unchanged, the costs per fathom are expected to remain unaltered, therefore the profit per fathom must not fall or else column 13 judges and condemns him. Another claim advanced in support of column 13 is that "the progressive results will automatically induce greater speed in development, closer mining, and a higher degree of sorting, all of which make for greater profit." Being a sweeping assertion without proof or support, it need not be met with detailed criticism. However, it may at least be suggested that the slow process of automatic induction through the leisurely guidance of quarterly returns is not the best available for deciding these ever changing calls of policy. In any case, Mr. Marriott is clearly under a delusion when he declares that greater speed of development, closer mining, and a higher sorting must lead to greater profit. On the contrary, there must be an economic limit, governed by current practical conditions, and when that limit is exceeded there can, by hypothesis, be no improvement.

Ore Reserves.—The treatment of ore reserves under the new policy raises a big question. In Rand practice, there is no such segregation and as a general rule 'ore developed' does not necessarily mean ore blocked out in readiness for stoping, but that ore which can be 'safely valued,' with due consideration for compensation of errors in the blocks of less thorough exposure. This introduces the element of judgment, but in any intelligent estimate of ore

reserves, promising to give results borne out by subsequent operations and at the same time representing the utmost knowledge of the property available, this factor must be employed. If ore ready for stoping is alone considered, reserves on the Rand would be greatly reduced and the position would be presented to shareholders in a dangerously unfavorable light, deceiving all save those intimately acquainted with the position in the mine. Mr. Marriott wishes to attach excessive importance to the winze connections. His arguments are, however, contradictory. First, he says that he wishes to induce European shareholders to base their estimates of share valuation for market purposes on the payable ore reserve, rather than the gold returns. This is a wise procedure, and one that will be doubly advisable when managers are driven by column 13 of the new returns to work out the blocks suitable to its requirements regardless of future economy and the ultimate maximum profit to be gained from the mine.

Later on, he states: "The area developed during the year will include only all reef which is available for stoping, without further winzing and raising. A system has been started since I left of stating that a drift of itself develops a certain amount of ore in the reef standing above it. A drift unconnected with other drifts develops nothing but itself and the rock that is taken out of it. If this were not so, then what have you developed when you have put through the necessary winzes and raises? You have already credited the drift with the development and therefore these latter show no further area opened up, whereas this extra work is essential before the ore reserves can be attacked." Under ordinary systems, the winzes do not add to our reserve. They merely increase knowledge of the reserve in the same way as subsequent stoping gives still further information. They do not add to the reserve of proved ore—though without them the blocks are valued with a rather lower degree of safety—but merely add to those ready for attack. This is a point about which the investor, whom Mr. Marriott quotes as an influence in his decisions, can care nothing. His estimates of the future must be based on the grade of ore that can be valued in the judgment of the company's engineers, whom he has perfect right to assume are maintaining an ample length of stope faces to meet mill requirements. It would be absurd, for instance, to give a mine a low valuation merely because at some period the winze connections were insufficiently advanced, while the reef disclosures of advance driving were of increasing richness. Compared with the work of driving—of having the shafts down and the levels out—the work of winzing and raising is almost insignificant. By enforcing the system of reckoning as ore developed only such areas as are blocked out for stoping, although other stretches of ore can be valued with very little less security, would mean withholding from shareholders information possibly of vital importance. How, then, can the introduction of such a scheme be of benefit to shareholders whom Mr. Marriott is aiming to serve? Another tendency of the proposed restriction of ore to that ready for stoping will arise in the non-appearance in estimates of that ground of doubtful payability, the winzing through which is delayed in favor of the richer ore. A strip of ore between the two levels will be known to be of poor grade and thus reduce the value of the payable ore or increase the percentage of unpayable, but not being winzed through will be omitted from the estimate. I admit that the whole question of ore reserve estimation on the Rand is one that would repay detailed investigation, so that, for the benefit of the whole field, uniformity might be established in the crucial points. But I consider Mr. Marriott's criticism and proposal are not applicable to the Rand. This is a technical question regarding which I should like to hear other local opinions, although its treatment may have little bearing on the new fathomage system. Regarding the application of the fathom to the presentation of ore reserves, it is difficult to frame condemnation too emphatic. In the first place—and this must be fully insisted upon—there is no connection between the grade of a mine and the 'gold content' per square fathom. As previously shown, a fathom representing the same gold may be 12s. ore or 36s. ore. A mine may therefore have treated in one year 50,000 fathoms at £15 per fathom with a profit of £3 per fathom and be shown to have an ore reserve of 100,000 fathoms at the same value per fathom and yet not have a single payable fathom in the mine.

Again, there is no fixed relation between the inclined area exhausted and the claim area, and the fathom as a unit of equipment capacity is meaningless. Even an engineer with inside information would have to convert his fathoms into tons before he could make any estimate of the life. It would be interesting to learn, however, how such an impartial authority as the Government Mining Engineer would view the matter upon receiving an estimate of life, for Profits Tax amortization purposes, based on the argument that because 50,000 fathoms were treated in 1909, the remaining 250,000 fathoms means a five years' life. Information would surely be demanded to indicate whether these 250,000 fathoms represent two million tons or five—a four years' life or ten. Just as there is a complete lack of definite expression in the use of the square fathom as a unit of equipment capacity, so is it a factor of dangerous looseness in its recognition as a fixed proportion of claim area, especially when made to bear responsibilities in the new quarterly returns, which the 'ton milled' is not, and could not, be expected to carry. It is true that a property of 1000 claims contains 1,778,500 square fathoms on the horizontal, or 2,050,000 square fathoms on the incline at a dip of 30 degrees, but it is not in reference to one of these fathoms that results are shown. This is where a false impression of the unit's significance may arise. The fathom employed is given as the fathom 'stoped' on all reefs. Assuming, for sake of argument, that this could be definitely shown, then on a mine with two or three reefs, each with varying degrees of payability, the total fathomage providing the units, may range from 2,000,000 to 6,000,000, according to the percentages of each reef mined and the scheme of

working. This circumstance suggests why no such extravagant importance should be attached to profit per fathom or any other unit, but should give greater weight to total profits and the maximum present worth of the whole property.

Pay Limit.—In regard to pay limit, Mr. Marriott has fallen into a most inviting trap. He stated in his address: "You have hitherto taken your mine working cost as the dividing line on which to base the payable reef standing in your mine. The standard of mine working costs, although it has not been varied to the extent that the tonnage milled has suffered from time to time, is still an unstable figure of comparison. Many of the necessary items of company expenditure are excluded, and without going into detail I can simply express the position by stating that the Profits Tax is just as much an item of working cost as the running of the mill." This presumably means that the pay limit will be raised, say, 1s. 6d. per ton in respect to Profits Tax and will throw into the unpayable class those blocks of ore estimated to stand between the old and the new limit —say 18s. and 19s. 6d. In other words, the blocks transferred from the payable to the unpayable, because they are estimated to yield no profit at all, are nevertheless being charged 1s. 6d. per ton in respect to a 10% tax on their profits. This is manifestly wrong. Whether Mr. Marriott means the Profits Tax to be added, at the mine's average figure, to the pay limit and thus charged against the barely profitable blocks with the false results mentioned is not quite clear. He has certainly stated: "In a properly equipped and developed mine only those blocks of ore should be worked which contain gold of an estimated value greater than the total cost incurred by the company in working them, under column 11." This figure does include the average Profits Tax. Elsewhere, however, he says: "Each section of rock must stand absolutely on its own merits, regardless of the cost or profit from any other reef section."

Disregarding the contradictory nature of these remarks and giving Mr. Marriott credit for not intending to charge a block showing a probable profit of 1s. per ton with 1s. 6d. for a 10% Profits Tax, it may be assumed that it is intended to charge against each block its own estimated tax. In this case it will be seen that while the rich blocks are bearing a Profits Tax above the average, the low-grade blocks are charged with a tax that gradually diminishes to zero as the old pay limit of working and general expenses is reached. Thus, there will be no change whatever in the pay limit, for the simple reason that those blocks which are on the pay limit cannot be debited with any tax and therefore the effect of Profits Tax on pay limit and the classification of payable and unpayable would be literally and absolutely nil. Thus the addition of Profits Tax to the pay limit, of which so strong a point is made under the new scheme, is fallacious in its influence, if based on the mine's average figure, or else it effects no change whatever, if added proportionately to the estimated profit of each block.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Soluble Gold Slime

The Editor:

Sir—In an earlier number of the *Mining and Scientific Press*, J. D. Hubbard, in commenting on zinc-box practice at Taracol, Korea, affirms that gold in the boxes is precipitated in an allotropic form and so rendered insoluble in a cyanide solution. From the appended data which I gathered while with the King of Arizona Co., it would seem that such a state of solution should be attributed to some local occurrence rather than considered a universal condition or property of the solution. No attempt was made to obtain the exact rate at which the gold dissolved. It is to be noted, however, that nearly one-half of the total amount was dissolved and removed in the first solution charge. The slow solvent action at the close may in some measure be ascribed to occlusion of the fine gold particles in a gray flocculent residual precipitate, presumably originating from base metals in the slime, and which became lighter in color with each successive decantation of solution. In carrying out the experiments, series I, 0.20 gm. of gold slime was covered in a bottle with 300 c.c. of the solvent and occasionally agitated, then settled and at the close of the stated treatment period, decanted through four filter papers and the filtrate assayed. The heavy slime remaining practically undisturbed on the bottom was then covered with the second solution charge. The daily working solutions taken from the sump were used in the tests. While time and facilities available did not permit of exhaustive experiments, there were no exceptions to the conclusion that gold precipitate is to some considerable extent soluble in cyanide solution.

Device to Free Air-Line of Water

The Editor:

Sir—I noted with interest the letter and sketch by A. L. Lamb, in your issue of September 3. Your readers may not perhaps be aware that on permanent air-pipe lines, the use of a regular water-trap is quite customary. It is considered good practice to place an air-receiver as close to the compressor, and a water-trap or separator at a low point in the main as near the drills, coal mining machines, or quarry machines, as possible. As stated in Mr. Lamb's letter, the water condensation, which at this point in the line, should reach its largest quantity, as the air will be coolest here, may be collected to the best advantage and drawn off, leaving the air dry and rendering freezing at the drill exhausts unlikely. Further, if an air re-heater can be used as is customary on surface work, the efficiency of the air-power will reach its highest possible point. One maker of mining machinery manufactures a standard water-trap and separator for this purpose.

S. B. KING.

Chicago, September 10.

A Hasty Conclusion

The Editor:

Sir—Your card received, informing me that your edition of July 23 contained something of interest to me. Your reckoning is correct. I overlooked a date, thence the error, one you could have corrected in a dignified way with less labor.

You published a private letter without the consent of the writer thereof, and violated a course of conduct which some publishers hold as honorable. Your performance has two aspects—evidently you were much in need of something to print; and you took the opportunity for a covert attack upon the State Mineralogist. Concerning that implied in ending your article, I will state that I am expert in handling metals, in putting into marketable form the gold and platinum contained in concentrates. I venture that you do not know one professional M. E. who can make such claim and verify it, and I am nearly certain that the person who produced your article would be outclassed in such work, whether he be or be not a somebody.

WILLIAM GREGG.

Grass Valley, September 7.

[Mr. Gregg will be remembered as the man who made a trip to Smartsville to purchase a mine on the strength of an old item of news re-published in our Anniversary Number, and somewhat hastily criticized us to others for publishing 'fake' news.—EDITOR.]

A Cyanide Problem

The Editor:

Sir—I note with interest the letter of 'Metallurgical Engineer' in your issue of August 27, commenting on the request of 'Mine Owner' for a method of dealing with antimonial ores by means of the cyanide process. 'Metallurgical Engineer' believes that it would be foolish for one in possession of the required information to make it public gratis, as such knowledge is the capital of him who has it. The standpoint is natural, and it is easy to understand its acceptance by the great majority of people. This is doubtless the reason why the columns of the technical press rarely give notice of the details of a really important new idea, and it is also the reason why the records of the patent office are so clogged with applications for patents on inventions that are considered important by their fond originators. The idea, however, seems to me rather near sighted. It

is true that the mine owner may be required to pay a high price for his information originally, but if mine owner's neighbor, having the same kind of ore to treat, requires that information, the chances are that he will get it by watching operations. Valuable information of that sort is bound to spread in one way or another, and it is futile to try to prevent it. On the other hand, if this information were published freely it is more than likely that it would require a trained metallurgist to apply it, and the man with the knowledge would get his job after all. There need be little fear that such information would be appropriated and used by novices. It requires a scientific mind and scientific training to apply scientific truths, and while the metallurgist is not protected by statute, he is amply guarded by the law of human capability. No one who has read the pleas of T. A. Rickard for the free publication of technical information can pass the matter by without thought. And the more thought given to the subject, the more clear it will appear that the one who gives this information is little likely to suffer by it. There is, however, a more important reason why 'Mine Owner' cannot receive an answer to his question in the columns of the press, and that is that his information is too meagre. Some ores containing antimony are easily treated with cyanide and others not so easily. It depends not only on the amount of antimony, but its condition and combination with other elements, so much so that it would require a whole book to include all the possible occurrences of the element in ores.

San Luis de la Paz, Gto., Mexico, September 2.

Decrease of Value in Ore-Shoots with Depth

The Editor:

Sir—In reference to O. H. Hershey's article on the 'Decrease of Value in Ore-Shoots with Depth,' in your issue of July 16, it may be suggested that while it is a well known fact that on the whole, the deeper we get, the lower the grade of ore, to attempt to cover the matter in a few words would be futile. Mr. Hershey's article is well amplified in that on the 'Economics of Secondary Enrichment,' by A. M. Finlayson, in the same number of the *Mining and Scientific Press*. That all mines decrease in value with depth is not always correct; for example, in 1890, when I left the Gogebic range, I believe that the prevailing idea of economic geologists was that most of the iron would be found above the 1000-ft. level. I was told only yesterday by a gentleman coming from that district that the Montreal mine had got a large body of hematite running over 68%, with hardly any phosphorus in it, at a depth of 1900 ft. In addition to this the Newport and Pabst, toward the eastern end of the range, show ore some 800 ft. wide at a depth, so I believe, below 2000 ft. A few miles away there is no doubt that at a depth of 5000 ft. the mines in the Lake Superior copper country have grown poorer in depth, the most noticeable decrease being in the Calumet & Hecla, as shown by the last report. I think a broad principle can be stated that the deeper one gets the poorer the ore becomes, though this is modified in a great many cases by the effects of secondary enrichment.

The whole subject has been studied by S. F. Emmons, W. H. Weed, C. R. Van Hise, and others, and there is much in the literature on the subject. An abstract of the conclusions of these men might be of service to the profession.

J. Parke Channing.

Cyaniding Sulphides

The Editor:

Sir—One of your recent correspondents asks for information on cyaniding concentrate. Following is a list of articles in which the subject is mentioned, which may interest him: *Bulletin* Amer. Inst. Min. Eng., S. F. Shaw; *Mining World*, June 1, 1907, Frank C. Smith; *Eng. & Min. Jour.*, April 3, 1909, Walter Brodie; *Journal* Chamber of Mines Western Australia, May, 1908, B. L. Gardiner; *Mining and Scientific Press*, October 3, 1908, A. E. Drucker; *Mining and Scientific Press*, September 26, 1908, F. C. Brown; *Eng. & Min. Jour.*, April 17, 1909, E. Walsh; *Mining and Scientific Press*, October 2, 1909, J. D. Hubbard; *Mining World*, November 27, 1909, Etienne A. Ritter; *Mining and Scientific Press*, March 19, 1910, A. E. Drucker; *Mining and Scientific Press*, April 30, 1910, A. E. Drucker; *Pacific Miner*, A. C. McIntire. Besides the above there are a great many short notes and quotations that give valuable information. If I were sure that I have correctly guessed the identity of your correspondent, I would dare suggest that there are just ten mining journals which should be considered indispensable on a big milling and cyaniding plant. One manager subscribes for nineteen such publications and says it is the best investment he has made. He has a list of sums saved which he credits to what the shiftmen have read in the little library, and if something substantial is not added every week he starts an investigation.

Mark R. Lamb.

Milwaukee, Wisconsin, August 29.

The Government cement mill at Roosevelt, Arizona, completed the grinding of the last pound of clinker about the first of June, and will probably be dismantled at once. It has been in operation nearly five years, and has produced 330,000 bbl. of cement, most of which has been furnished to the contractor building the Roosevelt dam. The remainder has been used in the power-house, canals, flumes, and auxiliary structures. The mill was built on account of the high cost of transporting cement to the site, which is quite inaccessible. The Government engineers estimate that the mill has saved about $650,000.

The Tieton project of the United States Reclamation Service, in the State of Washington, includes about 30,000 acres of land which will receive water from the Tieton river through a main canal about 12 miles long. In the construction of this canal concrete lining cast in sections was used instead of the usual lining poured in place.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Since the use of reinforced concrete has become quite general in building construction the demand for some substance that will make it water-proof has arisen, and many firms now have placed such compounds on the market. Some of these are mixed directly with the concrete, while others are applied as a coating to the surface.

Organic matter in old 'tailing' if abundant, interferes with cyanidation by acting as a reducing agent and so decreasing the amount of oxygen available for the reactions. If the material is sufficiently valuable to warrant roasting the organic matter can be eliminated in that way. Usually, however, this is out of the question. It frequently happens that spreading the tailing out in the sunshine, with repeated plowing and harrowing, will cause enough of the vegetal material to oxidize, to permit of cyanidation. This plan is worth trying, though it will not, of course, accomplish much where carbon in the form of graphite or even wood is abundant. Wood fortunately does not interfere with reactions and is only troublesome to the extent that it clogs pipes and classifiers.

Coal briquettes were produced in the United States last year in greater quantity than ever before, according to the U. S. Geological Survey, but the output is still insignificant compared with the 18,000,000 tons made annually in Germany. The American product in 1909 is reported as 139,661 short tons, valued at about $453,000. This is an increase of 54% over the production of 1908. The reason for the much greater production in Germany is stated to be the cheapness of labor there, the greater cost of coal, and the practice of coking coal in retort ovens which yield a large quantity of pitch suitable for use as a binding material for briquettes. The Geological Survey states that here the briquette industry is held back by the large supply of cheap natural fuel, by the high cost of labor, and by attempts to exploit secret processes for which extravagant claims are made but which have failed to make good.

Qualitative determination of copper in cyanide solution is as follows: Take 100 c.c. of the cyanide solution, heat to boiling, and add 10 c.c. HCl. After a few moments add 0.5 gm. $KClO_3$, boil until most of the chlorous gases are expelled, and add 10 c.c. ammonia. The solution will be colored blue if copper is present. Clennel gives this method for the quantitative determination, but with this addition; after adding the ammonia, boil, cool, dilute to 50 or 100 c.c., according to the density of the color, and filter into a Nessler tube. The tint of the liquid is then compared with that of a series of standards made by adding measured quantities of copper solutions (1 c.c. = 1 mg. copper) to 5 c.c. strong ammonia and diluting to 50 or 100 c.c. In an ordinary case the amount of copper will be from 5 to 15 mg. and a series of standards may be prepared differing by one milligram.

The size of culverts through railway embankments which is required by law was stated some years ago by the Arkansas Supreme Court in a case that has since been an important precedent in that part of the country. Recently this decision has been reaffirmed by the court in the case of the St. Louis Southwestern Railway Co. *v.* Mackey, 129 S.W. Rep. 78, as follows: "It is the duty of a railroad company to provide proper and sufficient openings or culverts for the escape of the water of all streams crossing its roadbed, so as not to flood the land of other riparian owners, whether at ordinary stage of water or during floods which could reasonably have been foreseen and guarded against; and if it fails to provide such openings it is liable to any person damaged thereby." In the recent decision it is pointed out that if a flood is of such overwhelming and destructive character as to produce injury by its own force, independently of any other real efficient cause, the railroad company is not liable. But if the injury is produced by the combined effect of a flood and the concurring negligence of the railroad, then the latter is liable for it. This is because it is an established legal principle that where two concurring causes produce an injury, which would not have resulted in the absence of either, the party responsible for either cause is liable for the consequent injury, and this rule applies where one of the causes is "an act of God," such as an unprecedented flood.

The re-located line of the Panama railroad is 46.2 miles long, or about 1 mile shorter than the old line. From Colon to Mindi, 4.17 miles, and from Corozal to Panama, 2.83 miles, the old location is used, but the remaining 36 miles are new road. From Mindi to Gatun, the railroad runs in general parallel to the canal, and the maximum grade of the line, 1¼%, is in this stretch, where the ascent from nearly mean sea-level to 95 ft. above is made. At Gatun the road leaves the vicinity of the canal and runs east along the valley of the Gatun river to a point about 4½ miles from the centre line of the canal, where it turns southward again, and skirts the east shore of Gatun lake to the beginning of Culebra cut, at Bas Obispo. In this section there are several large fills, and the maximum elevation of the line is reached, 110 ft. above mean sea-level. Through Culebra cut, the road will run on a berm on the east side, 10 ft. above the surface of the water. From the south end of Culebra cut, at Paraiso, it will run practically parallel with the canal to Panama. The maximum grade between Gatun and Panama is 0.45%, and the maximum curvature is 6°. Where the railroad crosses the Gatun river, a bascule steel bridge is to be erected, and a steel girder bridge ¼ mile long with a 200-ft. truss channel span, is in use across the Chagres river at Gamboa. Smaller streams are crossed on concrete culverts. Near Miraflores, a tunnel 736 ft. long has been driven through a hill. The cost of the new line is estimated at $7,225,000.

Special Correspondence

KALGOORLIE, WESTERN AUSTRALIA

Increased Mill Capacity. — South Kalgoorlie Sinking. — Output.

A good deal of construction work is still under way in our mills, all tending toward an increased tonnage to meet the decrease in value of the ore. A No. 7½ Gates breaker has just arrived for the Associated. It is proposed to install skips in the main shaft, when ore-bins have been cut out at certain levels in the mine, and these will be emptied direct into the new crusher, and from this to the mill-bins. The Great Boulder company is installing two new Babcock & Wilcox boilers, while other additions to the mill are about complete. The erection of a 1000-kw. exhaust turbo-generator is now being hurried at the Horseshoe. It is rumored that the Lake View & Star company is to add 25 stamps and grinding plant to its existing 75 head. The tramway to the recently amalgamated Star leases is now being laid for the conveyance of ore to the Lake View mill. At the Perseverance, the new mill is

Fire at Perseverance Mill October 19, 1909. The New Mill is Now Ready.

finished, and the furnaces are being heated up. The new drum shaft for the main shaft hoist is in position, and the engine is being rapidly put together again. The Perseverance plant now embodies 10 Heine safety boilers for the Austral Otis (Melbourne) hoist, and two 30-drill Walker air-compressors and condensing plant; electrically-driven jaw and Gates type breakers, belt conveyors, eight No. 8 Krupp ball-mills, conveyors, elevators, six Edwards duplex furnaces, grinding pans and tube-mills, agitators, and filter-presses. The new portion of the mill seems to be almost perfection. At the Hannans Star, a vacuum slime-plant is well on toward completion. This will be about the same capacity as that on the Lake View Consols, namely, 9000 to 10,000 tons per month. There is a big heap of old residue in the dump, and it will take all of two years to treat it. Some of it should be of fair value, as a great deal of custom work was done in the old mill, large amounts of it being rich. The old mill consisted of two No. 5 Krupp mills dry crushing, mixing with KCN, rough classification, tube-milling the coarse product, agitation of the slime with BrCN, and filter-pressing. Like the Lake View and Oroya Links dumps from similar treatment, it is probable that the vacuum treatment results will not be higher than 60 to 70 per cent.

The South Kalgurli is sinking to 1800 ft., and then will go a further 200 ft. The old residue dump on this mine, that used to make such a dust in summer, is now being used by the Perseverance for filling stopes. The Kalgurli, in its cross-cut at 1550 ft. has passed through 25 ft. of ore worth $25 per ton, and it seems that the diamond-drill results will be proved by this cross-cut. Recently some telluride of copper was found in the Kalgurli mine, and Mr. Patton, the chemist, is to prepare a paper on its occurrance, along with other tellurides, for the local branch of the Aus. Inst. Min. Eng. Complete analyses have not been made yet, but it is thought that it is not exactly of the same composition as rickardite, the copper telluride from Cripple Creek. Kalgoorlite has been found in fair quantities in this mine.

The Commission on Miners' Phthisis is taking evidence in Kalgoorlie, both underground and mill conditions and employees being examined.

Returns from the principal mines are as follows:

*Treatment of dumps. †Loss due to heavy capital expenditure.

MEXICO

Pacific Smelting & Mining Co. —Sonora Copper Smelter Co. —Nueva Luz Cross-Cutting to Mother Lode.

The Pacific Smelting & Mining Co., its affairs readjusted, ample capital available, and under new management, is preparing to assume an important position in the mining industry of the west coast portion of Mexico. The present officers are Melbert B. Cary, president; George M. Ryall, vice-president; and Courtenay De Kalb, general manager. The company owns, through the Compañia Metalurgica y Refinadora del Pacifico, a subsidiary organization, the 350-ton smelting plant at Fundicion, State of Sonora, on the Southern Pacific Railroad of Mexico, and this plant is to be operated as a custom smelter, on broad-gauge lines and with a view to an important part in the development of the rich mineral territory tributary to it. Fundicion is 141 kilometres south of Guaymas, 173 kilometres north of San Blas, the junction of the Southern Pacific and Kansas City, Mexico & Orient roads, and 392 kilometres north of Culiacan, the Sinaloa capital. It is midway between Corral and Navojoa, the junctions, respectively, of the Yaqui River line and the Alamos branch of the Southern Pacific. The company also owns, through the Anita Copper Mines Co., the Yaqui Mining Co., and other subsidiary organizations, a number of valuable mines in the State of Sonora, and while it is planned to make these mines regular contributors to the smelter, the building up of a big custom business will receive particular attention. The ores of the El Cobre mines of the Anita Copper Mines Co., 25 miles northeast of Fundicion, are highly silicious, and it was

originally planned to make these mines the chief sources of supply for the smelter. This meant the heavy penalizing of silicious custom ores, in a district where at present the available ores are largely siliclous, and consequently these plans have been dropped by the new management. It is held that the silicious El Cobre ores will be of much greater value to the Fundicion plant in the future, when the tributary territory begins to offer basic ores. Traction engine trains, purchased by the former management to haul El Cobre ores, are to be sold, on the ground that existing grades and rainy seasons preclude satisfactory operation, and eventually a narrow-gauge railroad will be built to connect the mines and Fundicion.

The Fundicion smelter is the centre of a small town. There is a two-story hotel, a school, 59 American style cottages, and many dwellings for Mexican workmen. In order to conform to the provisions of the State concession, the plant was blown in during May, 1908, and operated 15 days. No ore has been smelted since that time, but periodically the boilers have been fired and the machinery operated with the object of keeping the equipment in good shape. The concession under which the smelter was built exempts the plant from all State and municipal taxes for a period of 12 years from June 1, 1908, and it is estimated that the saving by the exemption will amount to over 4% on the gross value of the output. There is at present at the smelter ore to the amount of 4000 tons, having a value of $112,000, and fully 2500 tons of coke. The smelter and other property of the company at Fundicion represent an investment of approximately $450,000.

George M. Ryall, vice-president of the Pacific Smelting & Mining Co., is the man who several years ago secured the big Ryall exploration concession in the Yaqui River region of Sonora. He organized the Yaqui Mining Co. to denounce and develop mineral ground within the boundaries of the concession, and this concern was merged with the Pacific Smelting & Mining Co. A total of 2700 pertenencias, or 6669 acres, was taken up before the expiration of the concession last spring, and several very promising properties will now be extensively developed. The General Development Co., a Lewisohn concern, is pushing the development of Ryall concession properties held under an option to purchase for $100,000.

The Sonora Copper Smelting Co., a Kansas City concern with a capital of $3,000,000, expects to have a 100-ton smelter in operation in the Magdalena district of Sonora early in 1911. The equipment is on the ground and work is in progress at the smelter site. The mines are three miles from Noria, a station on the Sonora railway, and development has been in progress three years. The proved ore is estimated at over 300,000 tons. A wire-rope tramway will carry the ores from the main traction adit to the smelter bins, 3500 ft. distant and 450 ft. below, and this tramway will be built to handle 500 tons per day in anticipation of the early increase of the smelter to that capacity. The company has secured from the Sonora government a concession exempting the plant from State taxes for twenty years, and providing against the granting of similar exemptions to other smelters in the Magdalena district during that time. A. M. Conrad, who located the mines in December 1906, is president and general manager of the company.

French capital, which of late is showing an inclination to become prominently identified with the mining industry of Mexico, may have an important part in the Oro Grande project for the re-opening of the famous old producers of the La Luz camp of Guanajuato. Representatives of the Oro Grande Mines Co. have been in France for some time, and French engineers are now on the way to Guanajuato to make examinations. On their report will depend the investment of much French money in the enterprice. The company has a capital of $9,750,000, of which $2,750,000 is preferred and $7,000,000 common. At the reduction plant of the Guanajuato Amalgamated, taken over with the mines of that concern several months ago, the Oro Grande company is now treating 300 tons per day, a part of which is ore from the dumps of the old La Luz mines. A profit of from ₱15,000 to ₱20,000 per month is being earned, and this is being applied to wiping out an indebtedness of ₱211,000, assumed at the time of the Amalgamated deal. This deal was largely a stock transaction. The old producers of La Luz and the adjacent ground that the company holds represent a cost of about ₱1,000,000. The Amalgamated plant is to be increased by additional tube-mills, and later, if the plans are carried out, a big plant will be built at a more convenient location.

Now that the Nueva Luz cross-cut, designed to intersect the mother lode of Guanajuato at depth, is in progress, mining men of the district are speculating on the result in the event no pay-ore is found. It is agreed that if the ore is found to continue to depth it will mean new life for the district, but opinions differ as to the effect in the event the Nueva Luz development proves that Guanajuato is not a deep camp. The cross-cut is being driven from the 600-metre level of the Nueva Luz shaft, and it will strike the Veta Madre 500 ft. below the deepest antigua working. The Mineral Development Co. has collected from the Federal Government a subsidy of ₱15,000 for the 100 metres of the shaft below the 500-metre level. The Guanajuato Reduction & Mines Co. is now treating from 20,000 to 22,000 tons of dump ore and mine fillings per month. Good profits are being earned. A parallel vein that greatly increases the value of the Carmen property has been cut on two levels by the Carmen-Guanajuato Gold Mining Co. The vein averages 25 ft. of good milling ore.

The reduction plant of the Virginia & Mexico Co., the first modern plant built in the Hostotipaquillo district of Jalisco, is idle pending new development. The manganese ores now available are extremely hard to treat, and a satisfactory extraction appears doubtful. With depth it is expected to secure less rebellious ores. The Espada Mines Co., formerly known as the Vick Mining & Milling Co., which is developing the old Espada, Deseada, and San José mines and adjacent virgin ground in the Hostotipaquillo district, has arranged to mill at the Virginia & Mexico plant. An aerial tramway will be built, and deliveries will be started about March of next year. In the last five months the Consolidated Mining Co. has shipped ₱70,000 worth of ore from the Casados mines in the Hostotipaquillo district. This ore was taken out in development work. Equipment for the proposed reduction plant is being assembled. The initial capacity will be about 150 tons per day.

SALT LAKE, UTAH

International Smelting & Refining Co.—Utah Metals Co.—Alta Hecla-South Columbus Consolidation.

The Tooele plant of the International Smelting & Refining Co. now has four of its five reverberatory furnaces in operation, although not at full capacity. This will be the normal operating equipment, it being the intention to hold one furnace in reserve. The capacity of the furnaces is 300 tons each, but they are not treating much over half that amount at present. The South Utah started its mill the first of the month, and this will give the plant at Tooele a fine concentrate high in iron and sulphur. Small quantities of ore from other mines are also being shipped in so that by the time the plant is ready to operate at full capacity there should be little trouble in keeping it supplied.

A group of Boston capitalists who are interested in the Utah Metals Co. have made an inspection of the property and have expressed themselves as pleased with the progress which is being made. Few people, even hereabouts, realize that this is one of the most important mining projects of this great camp. The tunnel will be 11,000 ft. long starting from a point near the Utah Consolidated in Bingham and terminating in Middle canyon, Tooele, at a point about five miles from the International smelter, and well above it, so that an aerial tram would afford easy transportation and give a considerable excess power. This gives a route of seven miles for the transportation of Bingham ores to the new smelter against a railway haul of nearly

fifty. The tunnel develops a flow of water which is reckoned on for at least 500 hp., and water rights in the canyon supply a sufficient amount for all work in connection with the driving of the tunnel. The company owns about 3500 acres of ground in the proved mineral district of Bingham, and all over its undeveloped ground are prospect holes, many of them showing ore or good indications. The work has already opened some good looking territory, but active development through the tunnel will not be attempted until it is driven about 2000 ft. farther, when it will be under some known bodies of lead-silver ore at a depth 900 ft. below the present workings. The tunnel is now in something over 4000 ft. and should be at the half-way point by the end of the year. Meantime at Park City the Snake Creek tunnel is going ahead at the rate of 12 ft. per day. Work was begun the middle of May, but only 1200 ft. has been driven to date, owing to the fact that the equipment has not been fully installed. Pipe for ventilation is now at hand and a gasoline locomotive for the haulage so that there should be no further delay in the work.

Notwithstanding the violent opposition of a minority of the stockholders of the South Columbus both this company and the Alta Hecla voted in favor of the consolidation of the two companies. At the South Columbus meeting over 350,000 shares of about 400,000 present voted for the consolidation. There is no doubt that the two companies can be worked to better advantage as one, but the South Columbus minority maintained that the basis of consolidation was unfair to their company. The discovery of gold in the Deep Creek country is causing some interest. This country is known to have large deposits of lead and copper, but the latest is that two good sized veins of gold ore running well above $100 per ton have been opened up. The Deep Creek region is one of great possibilities and such a discovery is not surprising. Announcement is also made that two of the mines of this district will be opened for the production of a gold and bismuth ore. The bismuth is especially desirable, as it is expected that the demand for it will increase for use in storage batteries, bismuth being an essential feature of the new battery which Edison is putting on the market. The Westrich Drill Co. has been organized in this city for the manufacture of a hammer-drill.

GOLDFIELD, NEVADA

Goldfield Consolidated.—Combination Fraction.—Florence. — Nevada Eagle.—Atlanta.

A continued shortage of water caused a material reduction in the output of the Goldfield Consolidated Mines Co., following the period in which repairs were being made to the mill, until the month of August, when the plant resumed treating nearly its full capacity of 900 tons per day. This obstacle to operations on a full scale has now been removed, some rain having fallen to replenish the depleted supply from springs and the company having laid pipelines from some of the deeper abandoned shafts on its territory, which will in the future insure an ample supply at all times. Under ordinary circumstances the Consolidated is enabled to obtain an ample water supply from the water company which furnishes the town of Goldfield and the mills of the district, this water being piped from Magruder mountain near Lida, thirty-five miles from Goldfield, but there was little snow in the mountain country last winter and until recently rain had not fallen in the desert for five months. New construction at and near the mill is practically completed and all new buildings are absolutely fireproof and sufficiently removed from the main structure to insure against the spread of fire and are equipped with the most approved fire-protection devices. At Jumbotown and at a point nearly equadistant from the Clermont, Mohawk, and Red Top shafts, are being erected the storage battery plant, with a capacity of 2500 hp., the central transformer house, electrical machine and supply house, and the assay laboratory. The structural work on these buildings, all of which are steel and concrete, is nearly completed. This construction should be finished in October, when some important economies in operation will be effected, the recent large items for construction will be eliminated, and the company's profits will be correspondingly enhanced. The August record for the advance of new development, 3297 ft., affords an indication of the large amount of this character of work in progress and the results are attested to by the average gold content of ore from new headings, 2.14 oz. per ton, a grade considerably higher than the average treated in the mill. One of the most notable of recent developments has been the opening of the big vein on the Combination, first developed by the Hampton stope, on the bottom level a depth of 480 and 100 ft. below the sill-floors of that stope, which has yielded a vast tonnage of rich ore above the fourth level, for a width of over 100 ft. at one point and 300 ft. in length. The tonnage from the Clermont has been increased of late and is now nearly equal in volume to that taken from the Mohawk. An improvement is reported in the character of new headings in the Laguna, where good mill ore has been taken from the 600-ft. level for the past two months. This point in the vein is 230 ft. vertically below the deepest of the Red Top workings, and as the vein is more than usually flat here a large area of stoping ground will be afforded in this orebody. Development at a point between the Mohawk and Red Top main workings, including the Gold Wedge fraction, formerly the property of the Jumbo Extension company, has proved highly successful. This orebody was first penetrated on the 450-ft. level, but proving to be erratic in character an intermediate cross-cut was driven to the vein, and on this level the stopes now being opened give promise of a heavy production and the quality of the ore exposed is excellent. With the exception of seams of high grade the best average of ore from new workings has been that of the product of newly opened territory, at a depth of 180 ft., on the Combination. In August 285 tons of ore taken from this drift returned an average of $119 per ton. The Red Top maintains its usual production and the grade of the product, always more uniform in value than that from the other mines, has been second only to the Clermont ore.

Preparations are now being made by the manager of the Combination Fraction to increase the daily output, treated at the Nevada Goldfield mill, to 100 tons. The plant has been successfully treating 50 tons per day, but the water famine has prevented a larger production by this company. The installation of an ore classifier and improved equipment in the cyanide department has materially enhanced the efficiency of the plant and the manager declares it is now in condition to treat, at a low cost, all the ore that can be produced readily under present conditions. No official report has been issued by this company for some time past, but its financial affairs are said to be in good shape. The mine has a large tonnage of excellent mill-ore exposed on the 500-ft. level, and development on the other orebody to the south and west has been attended by good results between the 280 and 350-ft. levels.

The Florence Goldfield maintains a production of 140 tons per day and mill-heads have advanced recently owing to the supply of ore of better grade coming from the 350-ft. level to the north and near the old Reilly lease. The vein opened in exploring this ground is being developed to the south and a stope has been opened for over 200 ft. in material of excellent grade and contains seams of high-grade ore. At this point the vein has not been worked above the 350-ft. level, and it promises to yield a large tonnage for a distance of several hundred feet in length. The main shaft of the Florence has been enlarged to two compartments and man-way by raising from the 500-ft. level to within 100 ft. of the surface. This work has proceeded rather slowly owing to the necessity for hoisting ore through this shaft, the capacity of the aerial tramway from the Little-Florence shaft being insufficient to supply the mill, though a considerable volume is being brought from the Little-Florence and Rogers lease territory. With the completion of the main shaft the known orebodies will at once be opened on the 500-ft. level and the shaft will be sunk without delay to a depth of 1000 ft. A shipment of 50 tons of ore assaying $40 to $55 per ton has been sent to

the sampler from the Nevada Eagle mine, four miles west of the town. The ore was taken from a raise above the 250-ft. level, where a vein of good proportions is exposed and the miners are breaking about 30 in. of material that will return a profit from shipping. A mile north of the Eagle, driving is in progress on the 120-ft. level of the Nevada Victor. The several Atlanta lessees continue active development on levels down to the 730-ft., the deepest drift of the Precious Metals Co.'s lease. Two orebodies of excellent appearance and good proportions have been opened on the 400-ft. level of the Victor workings of the C. O. D. Consolidated and a drift is nearing the same vein on the 500-ft. level.

BUTTE, MONTANA

Butte Suits. — Attorney General Visits Anaconda District.— Barnes-King.

The days of the old mining litigation have been revived by the institution of a suit against F. Augustus Heinze for $15,467, the suit being the outcome of a judgment for damages secured by Johnston T. Hagerty against the Hypocka Mining Co. for the loss of a leg while at work for Heinze's company. After the judgment was secured Hagerty was unable to have the same satisfied, so he applied to the court for the appointment of a receiver. The Hypocka Mining Co. was organized by Heinze during the days of the litigation with the Amalgamated Copper Co., and its property consisted in the ownership of the cage and some other property of the Minnie Healy mine. This property was afterward sold to Thomas F. Cole for the sum of $25,000. It is alleged in the complaint that the proceeds of this sale came into the possession of Mr. Heinze and that he has not accounted for the same, having, it is alleged, wrongfully appropriated them to his own use. It is also asked that an attorney fee of $5000 be allowed together with $1000 to pay the costs of the receivership. The suit brought by minority stockholders of the Parrot Copper Mining Co. looking to the appointment of appraisers for the purpose of valuing the property, has again been continued, this time until October 31. This suit, it will be remembered, was started by Boston holders of the stock shortly after the special meeting of the company at which it was voted by a majority of the holders of the stock to dispose of all interests to the Anaconda company under the merger terms.

The first round in the suit of the Anaconda Copper Mining Co. against the Butte-Ballaklava Copper Mining Co. is finished and the court has ruled against the Butte-Ballaklava people so far as relating to the application for a modification of the restraining order so as to make it reciprocal. In doing so the judge pointed out that the defendants had not made out a showing of ownership or trespass and the court therefore had nothing but counsel's verbal statement as to the conditions. This portion of the motion for a modification of the restraining order was continued indefinitely to allow the defendants an opportunity to make proof of ownership when it will again be argued before the court. The judge, however, did grant the Butte-Ballaklava company permission to enter the property in dispute and to timber where necessary. This was not objected to by the attorneys for the Anaconda company. In asking for the reciprocal order, the attorney for the Butte-Ballaklava company stated that the plaintiffs had penetrated into the Butte-Ballaklava mine through the High Ore workings for the purpose of inspecting the property. An impression has been created that the Butte-Ballaklava is closed down, which is entirely untrue. The only work stopped is in what is known as the disputed ground. A suit has been instituted against the Anaconda Copper Mining Co., the owners of the Butte Sampling Works, for $1568 which the Pony mining interests claim is due for ore shipped to the smelter sampler. The Pony owners claim that the ore shipped was valued approximately at $137 per ton and that when they received the smelter returns they were given less than $30 per ton for the ore. Therefore judgment is asked for $1568 which represents the difference between the sum which they received from the Anaconda company and the amount which they claim was the actual value of the ore.

G. W. Wickersham, U. S. Attorney General, with Frank Cole, his private secretary; Lygon Johnson, special Government prosecutor; Mr. Freeman, U. S. District Attorney, and others, made an examination of the Deer Lodge valley last week with the object in view of becoming acquainted with the conditions existing in regard to the alleged destruction of vegetation from the smoke and gases from the Washoe smelter. John D. Ryan, president of the Amalgamated Copper Co.; C. F. Kelley, head counsel of the Anaconda company, together with R. L. Clinton, C. M. Sawyer, and N. J. Bielenberg, attorneys representing the Deer Lodge valley ranchers, were also in the party. The various points where the smoke and gases are alleged to have done the most damage were visited as was also the Washoe smelter. The attorney general and his party were taken through every part of the big smelter and shown every degree in the treatment of the copper ore from the time it arrives at the smelter until it is made into copper. A sapphire weighing 5¾ carats was recently turned out from the Yogo-American Sapphire company's property in Fergus county of this State. It is pronounced the largest specimen ever found in America. The new mill of the Iron Mountain Tunnel Co. will be in operation about the middle of November. The manager says that when the mill is running the company will ship about 100 tons of concentrate per week. The Barnes-King mine is once more in operation and the company believes that it cannot only be worked sufficiently to bear all expenses of operating, but that there can be a profit realized besides. It was at first intended to lease the property, but Mr. Fischer and the officers of the company in New York, after consulting with mining men, decided to work the property on their own account. At the present time 25 men are employed and it is possible the force will be increased in the near future if present operations turn out satisfactorily. The new electrically-driven equipment of the Keating Gold Mining Co. is now in full operation and good work is being accomplished. A fine body of ore has been opened more than five feet wide and the assays run from $20 to $25 per ton. Two new stopes have been started. The ore will be shipped at the rate of a car per day. It is stated that there is sufficient ore in sight to make shipments at the rate of 35 to 40 cars per month.

LONDON

Burma Mines Co.—Penhalonga.—Dolcoath Report.

The Burma Mines Co. was formed in 1906 to acquire ancient lead-silver mines in upper Burma not far from the Chinese border. Bewick, Moreing & Co. are the managers, and H. C. Hoover is on the board. The mines had been worked by the Chinese presumably for silver only. The carbonates had been practically exhausted and enormous quantities of slag high in lead and low in silver were found scattered all over the valleys. Two smelters commenced operations in the early part of 1909 and during the year treated 11,850 tons of slag and 912 tons of ore, producing 5029 tons lead and 26,398 oz. silver. The slag averaged 46% lead and 1.78 oz. silver, the extraction being 88% of the lead and 96% of the silver. The bullion sold for £57,222. The operating costs included £24,833 for the transport of the slag to the smelters, £23,007 for treatment, and £11,682 for freight and realization of bullion. The profit and loss account also contains items of capital expenditure on the railway, smelter, stores, debenture interest, London expenses, and mine development, amounting in all to £121,000, and the adverse balance is £123,201, which is carried to the balance sheet. The company has been overweighted with capital and there were many different classes of ordinary and preference shares. Since the close of 1909 the capital has been rearranged by consolidating all the shares and writing them down to 312,046 shares of 4s. each of which 286,508 carry a liability of 2s. The total nominal issued capital had previously been £355,589. Reports by W. J. Loring and by Gerard Lovell, resident manager, are also issued. From these it appears that a third smelter has been

erected since the end of the year and that exploration at the mine shows that the Chinese had worked in sulphide ore as well as carbonate. An outline of the proposed plan of development is given, and it would appear that the profitable exploitation of the property will give the engineers an anxious time.

The Penhalonga company was formed in 1898 by the Anglo-French Exploration Co. to acquire a gold property in the Umtali district of Rhodesia, that had been previously tried several times. The ore contains gold and silver amenable to amalgamation, together with galena and cupriferous pyrite containing the precious metals. It is of low grade and its exploitation has always caused difficulties. A 40-stamp mill was erected in 1903 together with concentrating machinery and another 40 stamps was added later. The only dividend was 6% for 1907. The issued capital is £275,000 and there are £199,350 of debentures, some issued in 1905 and the others in 1907. The report of the consulting engineer, C. R. Pinder, shows that the content of the ore during 1909 is rather lower than during the previous year. The amount of ore mined was 198,604 tons, and after removing 41% of waste, 116,278 tons was sent to the mill. Only 60 stamps were running during the greater part of the year, owing to a greater proportion of the ore being removed before treatment. The average assay of the ore sent to the mill was 4.2 dwt. gold, 2¾ oz. silver, and 28½ lb. lead per ton. The recovery was 3.47 dwt. gold, 27 dwt. silver, 16 lb. lead, and just under ½ lb. copper. The total recovery was 20,149 oz. gold, 156,265 oz. silver, 943 tons lead, and 35 tons copper. Of this 8710 oz. gold and 7571 oz. silver were obtained by amalgamation, and the remainder was produced from 2424 tons of concentrate which was shipped to smelters in Europe. The value of the amalgamated bullion was £37,844 and of the content of the concentrate £74,140. Against the latter is £15,154 the cost of shipping and smelting. Mining, milling, development, redemption, and other costs at the mine brought the expenses to £104,305, so that the profit at the mine was £7680. Other costs were, debenture interest £11,961, depreciation £7997, London and other expenses £2069. The credit side was increased by £393 refunded from income tax and a few small items such as transfer fees. The eventual result of the year's operations was an adverse balance of £13,900. A notable feature of the operations this year was the more liberal sorting. As regards ore reserve the figures on December 31 were 150,175 tons of developed ore and 51,000 tons of probable ore. This is lower than a year ago, for the reasons that much of the ore included then will now be removed by sorting and that some of the probable ore included last year has proved to be unprofitable. The financial position of the company is serious, because the debenture interest has been in arrear since October, 1909. An attempt was made to raise funds by reconstruction so as to carry out a scheme of development suggested by Mr. Pinder and by H. A. Piper, but shareholders did not respond. The future of the company is uncertain.

The report of the Dolcoath tin mine, Cornwall, for the half-year ended June 30 shows that a profit of £13,018 has been made, but no dividend is being distributed, as money is required for the equipment of the new main shaft. During the six months 47,279 long tons of ore was mined, and 853 tons of concentrate produced. The yield was 40.4 lb. per ton, and the receipts £75,639. Of the production 772 tons was sold at £91 per ton, and 81 tons of lower-grade slime sold for £66 per ton. Sale of copper ore and interest brought the total receipts to £77,372. The cost of £59,304 and lord's royalty £5049, leaving a profit as rendered above of £13,018. Comparing these figures with those of the two previous half-years, the amount of ore crushed is slightly greater, but the yield appreciably smaller. During the first half of 1909, the yield was 1000 tons or 49 lb. per ton, and during the second half, 904 tons or 42 lb. per ton. The average price obtained has, however, been greater, so that the total receipts and the net profits are nearly on a level. The expenditure on capital account during the half-year was £11,762, of which £10,867 was spent on the new main shaft. The total expenditure of capital, obtained by the sale of shares, since the formation of the company, is £124,731, of which the new shaft accounts for £101,230. The company has approximately £33,000 of capital left in hand. The manager, R. Arthur Thomas, reports that on May 12 sinking was completed at the new shaft, when the bottom of the sump reached 3300 ft. vertical from the surface. Cross-cuts were then started in each direction. The main lode is 150 ft. south of the bottom of the shaft. Connection between the new shaft and the workings had six months before been made by a cross-cut at 2940 ft., and the ventilation of the mine was greatly improved thereby. The Killas shaft has been put in order and a skip-road provided. At this part of the mine copper-tin ore is found and it is intended to start mining it when more development work has been done. The company has had an Elmore vacuum plant on the spot for some years waiting for this ore to be mined. In the Stray Park portion of the mine there are large quantities of zinc-copper ore, and investigations and trials have recently been made in connection with it. Some of the old Cornish stamps are now being dismantled to make room for 12 new Holman air-cushion or 'pneumatic' stamps. These will be driven electrically and six of them should be ready for work at Christmas. Additional dressing plant is also being erected. The amount of development work done during the half-year was 2568 ft. In Cornish mines the fashion for giving exact figures for ore reserves has never been adopted. The lodes vary so much that such figures would be of no value. But at Dolcoath there must be a great number of working points where there are plentiful reserves of ascertained value, for the management is able to bring to surface almost any grade of ore to meet requirements. Looking through past records it becomes plain that low-grade ore is treated when metal prices are high, and vice versa; these circumstances could not be accidental. In fact, it is Mr. Thomas' boast that whatever the price of tin Dolcoath always makes a profit.

LOS ANGELES, CALIFORNIA

California Oil Industry.—Huasteca Petroleum Co.— Johnnie Mining & Milling Company.

The directors of the Western Oil Producers' Association met here September 17 and effected a permanent organization by the election of officers. Norman Bridge was elected president and William M. Erb secretary; five vice-presidents, representing various oil companies, were elected. Five field committees were appointed and chairmen named for the resolutions, publicity, membership, and finance committees. All of the directors were appointed a committee of the whole to bring about a consolidation with the California Oil Men's Association of Bakersfield. A lengthy meeting of the executive committee of the California Oil Men was held in Bakersfield during the week. By-laws were adopted and the name of the organization was changed to the California Oil Men's Association. The next meeting will be September 24. The by-laws adopted state that the purpose of the association is to take up with the proper authorities matters that affect legitimate claims to oil lands in the public domain of California, and to do whatever is possible to advance the oil industry and to promote the prosperity of the men connected therewith.

Following the resignation of S. C. Graham as secretary of the Western Oil Producers' Association, the directorate of which is said to be opposed to further Governmental control, a new organization, to be called the Oil Conservation Association, is now being formed. It is learned that a first draft of by-laws already has been made and that a meeting will be called early next week. The aim of this association will be to unite all oil operators who are opposed to the conditions that have existed in the past, under which valuable public property has been acquired by private interests without any consideration to the Government in exchange for it; who are in favor of the restoration to the public domain of all of the oil lands now wrongfully and illegally held by private interests, and of conserving for the benefit of the whole people that portion of the National resources

represented by public oil lands; and who believe that immediate and radical change in the law is necessary in order to regulate the manner in which private interests may acquire and operate such lands. The desire is not to withdraw publicly-owned oil lands from use, but to prevent monopoly and to secure a fair distribution of the wealth they represent. Personally, Mr. Graham believes in such legislation as would secure for the Government as large a revenue as possible consistent with the prevention of monopoly. He suggests a certain fixed royalty so that the President or any other Government official will have no reason or excuse to interfere with the handling of the product, or of changing conditions by the arbitrary withdrawal from use of public oil lands, or in any other manner. He believes that with a proper law, in which competition is provided for, there would arise no necessity of giving anyone the power to suspend its operation anywhere or under any conditions.

The shaft of the Johnnie Mining & Milling Co., fourteen miles from Amargosa, Nevada, is now down 900 ft. and a station is being cut at that level. As soon as this is completed a cross-cut will be started for the vein, which is

Johnnie Mine, Nye County, Nevada.

about 150 ft. distant. Up to the present time about 70 ft. of driving has been done on the ore on the 800-ft. level. This work shows the vein to vary from 7 to 10 ft. in width and from $3 to $20 per ton in gold. The showing so far is better than on the 700. Sinking in the shaft will be resumed before the end of the month, when the station on the 900 is completed. The shaft will be sunk to the 1000-ft. level. The Fraction Leasing Co., operating the Johnnie company's Fraction claim, started work about a month ago and within one week cut high-grade gold ore; little can be accomplished, however, until the hoisting plant is installed. Negotiations are still pending for the leasing of the Minnie May claim.

DENVER, COLORADO

Colorado Chapter of the American Mining Congress. — Deep Cross-Cuts.—Bard Creek.

The first meeting of the recently organized Colorado Chapter of the American Mining Congress took place late in August, and was not as well attended as should have been the case. The session was devoted mainly to the discussion of three questions, namely, mining locations on forest reserves, the sale of timber by the Government from its reserves in or close to mining districts, and the withdrawal by the Government of certain water-power sites and coal lands in the mining areas. In all three cases the argument was brought forward that the prospector and miner was about to be or already was a sufferer from the policy that the Government is pursuing. A committee of five was appointed to look into the first question, and one of three to collect evidence as to the second, both to report at the next regular meeting of the Chapter. No deferred action was taken as to the last. The discussion was pretty warm on all three points, in spite of the slim attendance. But as no prospectors or miners appeared with definite complaints, and no letters were read from such, the impression produced on listeners was to the effect that no real grievances existed on any one of these scores, and that the prospector and miner were quite able to take care of themselves. Also, that the Chapter was rather manufacturing a case against the Government. This is unfortunate for the first meeting, for if the organization is to gain any standing and spread into other States it must devote its attention to real issues.

Reports from the principal mining districts indicate that the year, so far, has been a most active one among the ore producers, and no deposits show up better than the old Boulder-Gilpin-Clear Creek fissure veins that represent the earliest discoveries in the State. It is doubtful if there is any other district in the West where so many steadily producing mines exist within such a small area. The mineralized belt in these three small counties is not over thirty miles long and five wide, but the output has been averaging nearly $3,000,000 per annum for the last fifty years, and shows no signs as yet of slowing down. There is hardly a square mile in this whole area that will not show up a dozen or more of producing mines or promising prospects. In some places the lodes are so close to each other that the claims are restricted to widths of 50 ft. It is also preeminently a region of cross-cut adits, for most of the stream-valleys are deeply cut, producing innumerable opportunities to attain great depth on the veins with bores of moderate length. The majority of these enterprises originate in the valley of South Clear creek and its tributaries, from Idaho Springs up to the Continental Divide at Argentine. Between these two points there are over fifty deep cross-cuts in various stages of advance, and more than half of them are over 1000 ft. in length, while several count their extension in terms of miles. Of course the majority, the very large majority, have not yet justified their existence by becoming profitable enterprises; and perhaps many never will. Yet they keep going on into the great mountain walls of the valley year after year, scarcely a season passing without the commencement of new ones. A big hill, flanked by a deep gulch, is an irresistable attraction to the average miner. There is no use in telling him that experience has proved that in the great majority of cases fissure veins do not show appreciable gain in width or quality of mineral content as depth is gained, for he can easily quote cases where the contrary has proved to be true, and his ground is always an exceptional case, or going to oe. So the work goes on from season to season, and with enough encouragement in the way of new orebodies to keep up the enthusiasm. In fact, this zone has held out in depth astonishingly, and as the bulk of the deep cross-cut work in progress is being done by individual miners on their own time, or by companies out of the profits of the mines they have opened, it would not be wise to discourage the miners, even if it were possible. Perhaps the most interesting of them all at the present time is that which is piercing the Continental Divide at Argentine. It is a very old enterprise, begun years ago by that famous but now almost forgotten promoter, 'Brick' Pomeroy, and was expected to open untold wealth in the way of silver-lead ores. The distance through the divide at the tunnel level is some 8000 ft., of which about 5000 has been completed. Some encouraging ore developments have been found, but it is now considered that in the end the bore will be used to carry a narrow-gauge railway connection between Silver Plume and Keystone, as that would give the C. & S. R. R. the shortest line between Denver and all points to the west of it. While on the subject of tunnels, mention should be made of the new enterprise in that line which is to start in Birdseye gulch, one of the upper tributaries of the Arkansas river, and running in a general southerly direction, will undercut Prospect mountain. For many years a group of enthusiastic mining men of Leadville have believed that this hill, which lies directly to the north of the famous carbonate camp, was good mining ground, and much money and labor has been laid out in shafts upon it, which have developed little else than water and promising indications if the water could be handled. This will be accomplished to a certain degree by the proposed work.

There is still considerable excitement in and around the

new camp on Bard creek, to the north of Georgetown. This is really a revival of an old district, for Lincoln mountain was prospected for silver ores in the early seventies, and was a disappointment. The new finds are of gold ore. At the Beshear claim a foot of four-ounce ore is reported, and there are some encouraging developments in several other properties.

NEW YORK

Phelps, Dodge & Co.—Porphyries.—British Columbia Mines. — Shattuck-Arizona Listed.—Globe Mines.

The most important event of the week in financial circles was the purchase by Phelps, Dodge & Co. Inc., of a large holding in the Rock Island railroad. Some weeks ago a group of English and American financiers, known as the Pearson Syndicate, found themselves overburdened with securities in a declining market. They were relieved of the stocks and a bad market situation was saved by radical action on the part of leading Wall Street banking interests. The house of Kuhn, Loeb & Co. played a part in coming to the rescue of the market and took over a large block of Rock Island; it is this stock which has been purchased from Kuhn, Loeb & Co. by the Copper Queen people. The entry of the Phelps-Dodge company into well known railroad fields was taken by some hasty observers to mean a change of activity from the field of mining and smelting. Nothing could be further from the fact, nor is the matter of the management and conduct of a railway by any means new to the Phelps-Dodge interests. They have long controlled both the El Paso & Southwestern and the El Paso & Northeastern which handle all of their freight in Arizona. As a matter of fact the reason for the present purchase is to insure the continuance of amicable relations between these lines and the Rock Island; the latter road being the only outlet accessible to the former.

The announcement is now made officially that, while the Utah Copper has not enough stock of record to give absolute control of the Nevada Consolidated, yet there is more than enough stock in the Utah treasury to be transferred in due course. From the present record Utah lacks actual numerical control by 5363 shares. That this merger will be carried through is now admitted on all sides. The further steps in the consolidation of the Guggenheim properties, are not yet so officially announced; in fact, the merger of Ray Consolidated and Chino mentioned as the next important move, is emphatically denied by both Sherwood Aldrich, who heads the Ray Consolidated, and C. M. MacNeill, the president of Chino. Nevertheless such denial is held to be purely diplomatic. There has been some talk of an issue of new stock by the Chino of 100,000 shares to complete the financing of the mill. This also is emphatically denied by Mr. McNeill. The market sharpshooters are drawing some interesting comparisons between Ray Consolidated, Chino, and Miami. All three are low-grade milling coppers, all are expected to begin production with a part of the milling plants in operation shortly after the first of the year, and all are selling for practically the same figures, between $17 and $19. Ray Consolidated has something of an advantage in the amount of ore developed, having 75,000,000 tons as against 28,000,000 tons developed on the Chino, and 16,500,000 on the Miami. Recent work on the Chino has, however, on that part of the property known as the Hearst ground, developed some 10,000,000 tons of 3% ore. This is new territory and it is looked upon as certain that further work will greatly add to this tonnage. A study of the potential production of these mines demonstrates very clearly that at least during the years that the porphyries are taking the best out of the ground they will hold the complete domination of the metal market by reason of the immense quantities of cheap copper produced, cheap because produced in such quantity. The deep-level mines will apparently have to wait until steam-shovel pits shall have deepened and expense increased before they can make great headway as competitors of the porphyries.

The shareholders of Granby are looking forward very hopefully for the coming statement which is to embody both the report of Otto Sussmann, the later report by the vice-president, Jay P. Graves, and a detailed financial statement. Granby's copper costs have been running too high to admit of adequate profit, yet it is anticipated that a cash balance of $1,000,000 will be shown as against $600,459 on hand June 30, 1909. Diamond-drilling on hitherto unexplored portions of Granby has shown pleasing results and the record of this work will go far toward offsetting the showing of depleted ore reserves chronicled by Mr. Sussmann, whose report precipitated the slump last December. British Columbia appears to have reached something of a turning point. Since the General Development Co. interests got out last winter the stock has lost public favor. Now, however, it appears to have accumulated a quarter of a million surplus in cash and some $100,000 worth of copper in transit, and in the meantime to have enlarged and rebuilt two of its blast-furnaces so that the company is considerably stronger than at any time within the past three or four years. The gold and silver content has been running high in the ores and has so far reduced copper costs as to enable the company to lay copper down in New York at 7c. per pound. In the present condition of the metal market a dividend is hardly to be expected. The officials have announced their intention of building up a cash reserve of half a million dollars before considering making any distribution.

The 350,000 shares of the capital stock of the Shattuck-Arizona Copper Co., of Bisbee, has been admitted to trading privileges on the Boston Stock Exchange. The Shattuck is one of the recent successes of the Bisbee camp and enjoys the distinction of having made some of the cheapest copper produced in the country this year. One dividend of $1 per share has already been received by the stockholders. The Guggenheims are, evidently, not to rest upon their laurels in the development of their string of low-grade milling coppers brought to the producing point in this country. The work of the Braden Copper Co., in Chile, is being pushed with all possible speed. The mill of 2000 tons per day capacity is expected to begin operations in March next; the first unit of 400 tons is to be in operation within a few days. The company has some 8,000,000 tons of ore blocked out, showing an average copper content of 2.9%. The Barney Copper Co., of Globe, has been organized by J. D. Copelin, of Globe, who was formerly at the head of the old Inspiration Mining Co., now the Inspiration Copper Co. The Barney group consists of 27 claims adjoining the Keystone and the Live Oak. The new company has 1,000,000 shares, par $5, of which 300,000 shares are being offered to the public at 30c. per share. It is said that a minority interest in the Live Oak Development Co., at Globe, is attempting to secure control of the property with the object of consolidating it with the Miami which it adjoins. The movement was defeated at the recent meeting held in Bisbee, and a board of directors elected on the issue of the indepndent development of the Live Oak ground.

The Red Mountain Railway, Mining & Smelting Co. is to be reorganized and the stockholders will be asked to make an exchange of stock and to contribute 10c. per share toward a treasury to be used in development. The properties of the Red Mountain are in the San Juan district of Colorado and lie quite near the Camp Bird. The district has some splendid producing mines, the Camp Bird being the best known, but there have been many mining losses in the district also because mine development in San Juan is expensive and many good properties have scored financial failure because of insufficient funds. The discovery on the Spearhead claim at Goldfield has caused considerable market inquiry for the adjoining properties, Kewanas, Blue Bell, and Grandma. There is no denying the popularity of Goldfield issues in the East. No other mining camp has ever had such an enthusiastic following. Any developments that could assist the camp would be as warmly welcomed in the East as on the streets of Goldfield itself.

General Mining News

ALASKA

(Special Correspondence).—Reports from the district surrounding Valdez indicate that a gold vein camp of some importance is being developed in that neighborhood. So far only comparatively small gold-bearing veins have been found, the largest averaging about 5 ft. in width, but as the ore is high grade and free milling, the camp is especially suitable for enterprises on a small scale. Within the last two months, probably a dozen finds of much promise have been made, and many samples of ore containing visible free gold are being exhibited. The excitement commenced with the beginning of a stamp-mill run at the Cliff mine, a property situated a few miles down the bay from Valdez. There a yield of about $1000 a day has been made throughout the summer from a comparatively small vein, the workings on which are stated still to be in $50 ore. This mine is being operated with an equipment that cost only about $25,000. The character of other claims is such that several of them can each be equipped as cheaply.——On Mineral creek, which runs northward from the bay, through a slate formation, but two or three miles from Valdez, several discoveries of high-grade ore have been made. From the Oregon, distant three miles from town, a trial shipment of 1000 lb. of ore from a 2-ft. vein has lately been made. A little higher up Daniel Kain has a 5-ft. vein of milling ore, this being the largest vein found on the creek. Around the head of the creek there are several veins, varying in width from 18 to 30 in., that give high assays near the surface. Preliminary development is being done at a number of places situated within a few miles of Valdez, and there is little doubt that some of the prospects will by next spring warrant the provision of an equipment similar to that at the Cliff mine.

Valdez, September 10.

The report of the Alaska Mexican Gold Mining Co. for the month ended August 15, states that the mill ran 31 days and crushed 20,412 tons of ore. The estimated gross value of the free gold was $34,509.96 with 380 tons of concentrate saved that was valued at $35,916.12 which brought the total production to $70,426.08. The realizable value was $67,800.98, and the operating expenses $29,261.56, leaving a net operating profit of $38,539.42. Construction expense amounted to $14,463.54. The yield per ton of ore milled was $3.45 and the stock of broken ore was increased 534 tons for the month.

ARIZONA

COCHISE COUNTY

Construction work is going on at both the Copper Queen and Calumet & Arizona plants at Douglas. At the Calumet & Arizona plant there are three 500 and three 300-ton furnaces, two of the original ones of 300 tons capacity having been increased to handle 500 tons. It is now proposed to enlarge the remaining smaller furnaces to the same capacity as the larger ones, thus increasing the capacity of the plant 600 tons.——A force of men is at work at the Copper Queen plant erecting an addition to the flue-chamber which is to cover a space of 5500 sq. ft. The frame of this structure is to be of steel, and the walls of brick, the same as in the original building. Besides this addition to the flue-dust chamber a separate flue is to be provided to carry the smoke from the converters to the stack. The smoke from the converters heretofore has passed through the dust chamber to the stack. Plans are now under consideration for the addition of a reverberatory plant that will cover a space of 3000 square feet.

GILA COUNTY

(Special Correspondence).—At a meeting of the stockholders of the Live Oak Development Co., held at Bisbee, September 13, Henry B. Hoviand, of Duluth, Hoval A. Smith, of Bisbee, and S. F. Kaufmann, of Chicago, were re-elected. A certain element of the stockholders attempted to dominate the meeting with a view to transferring control of the company to the Lewisohns who exploited the property of the Miami Copper Co., but were unsuccessful in their efforts. ——All development has ceased at the property of the National Mining Exploration Co. for the reason that the employees, failing to obtain their pay checks on September 10, refused to continue operations. It is possible that N. L. Amster, president of the Arizona Commercial Copper Co., who holds a note for $100,000 secured by the National property and payable September 24, may secure possession of the claims. ——At the Arizona-Michigan property all underground work except the sinking of a winze on the Old Dominion vein, has been discontinued.——The Miami Copper Co. is operating only seven machine-drills underground as the amount of development already done is in excess of that necessary for the beginning and maintaining of production.——The extraction adit of the Inspiration Copper Co. has been connected with the Joe Bush shaft on the 275-ft. level. The test mill built near the Joe Bush shaft will begin treating ore at the rate of about 75 tons per day within a month. ——The sinking of the McGaw shaft on the property of the Superior & Boston Copper Co. has been resumed and is now in progress at a depth of 847 feet.

Miami, September 16.

MOHAVE COUNTY

Shipments are now being forwarded from the Banner group of mines on Stockton hill to the Needles smelter, and it is reported that regular consignments of lead ore will be sent to the plant for the present and later the zinc ore will be mined.——The Tom Reed shipped $38,000 worth of bullion, the result of the semi-monthly clean-up.——The Gold Road shipped $20,000 worth of bullion, the results of the week's run.——Plans are being formulated for the driving of a 1300-ft. adit that will open the Samoan, Lucky Boy, and a number of other veins in the Chloride district at depth.

YAVAPAI COUNTY

Edward Ord, representing Eastern capitalists, has secured a 90-days' bond on the Kinney group of 14 claims in Eugenie gulch and will commence the work of examination at once. A 225-ft. shaft has been sunk on the ground and over 1000 ft. of driving done which exposes a large vein of free-milling ore.——Arrangements have been made for the resumption of work on the Mid Day property on the Peck lode near Mayer which is supposed to be the extension of the old Peck mines. About 500 ft. of development has been done which includes a shaft of 60 ft.——Work is soon to be resumed on the McMahon group and the old Zonia mines near Placerita.

YUMA COUNTY

Active development on the Eaton property in the Parker district has been started under the superintendence of Samuel Jacoby. There are 17 claims in the group on which a number of shallow shafts have been sunk and drifts driven showing a large body of copper-gold-lead-silver ore.

CALIFORNIA

AMADOR COUNTY

The Lincoln Consolidated Mining Co., which is reopening the old Lincoln mine at Sutter Creek, has issued call No. 2 for 10c. per share to carry on development. The statement details that the company has re-timbered the shaft 127 ft. and installed new cables, that the shaft is now opened 150 ft. and is still in heavy ground though it is expected to pass through this within the next 100 ft., and that the company has purchased the mineral rights of the town lots adjoining the property.——The old shafts at the Alpine mine are being cleaned out and re-timbered and new machinery will be forwarded to the property.

LASSEN COUNTY

The mining town of Hayden Hill was completely destroyed by fire and the mine has been closed down. Operations will be suspended till freight can be taken in next spring.

NEVADA COUNTY

A flood of water in the new workings of the Brunswick mine in the Grass Valley district caused operations to be

suspended temporarily and the men have been laid off. The new shaft is 450 ft. deep and about on a level with the old workings which are 1200 ft. deep and which are thought to be the cause of the trouble. It was known that the water would have to be removed some time but it was thought that the new shaft would be near its completion, 1000 ft., before this would have to be undertaken.——The chlorination plant at the Delhi mine has been rehabilitated and will commence treating a pile of 200 tons of concentrate that has accumulated from the operation of the mill. The work of sinking the new shaft has been completed and stopes opened that will supply the mill which will resume some time this fall.

SHASTA COUNTY

The dredge of the Consolidated Gold Dredging Co. sank in 16 ft. of water in the Sacramento river near the mouth of Middle creek while being hauled to a new point of operation. While passing over a riffle the water washed over the sides of the boat and flooded it. Practically no damage was done either to the machinery or the hull and it will be but a few days before the boat is raised and in operation again.——The town of Salee, a short distance from Winthrop which was burned last July, was destroyed a few days ago by fire.——J. B. Keading, manager for the Bully Hill Copper Mining & Smelting Co., has returned from the East and is now at the mine.——The Mammoth Copper Co. has finished the building of its stock piles for the winter and stopped running the aerial tram.

SIERRA COUNTY

It is reported that a new shoot of rich ore has been opened at the Gladstone quartz mine near Table Rock, and that there is a general revival of mining interest in that district. Operations are to be resumed at the Miners' Home drift mine and the adit will be driven to open the gravel.——E. R. Argersinger has obtained control of the stock in the Squires Mining Co. which owns property in the Secret Canyon district and is reorganizing the company to develop the claims. ——A 5-ft. vein containing considerable arsenical sulphide has been opened on the Roosevelt claim, three miles east of Forest.——W. A. Derrer and associates, of Los Angeles, are driving a drift on the vein at the Alpha Derrer group on Rock creek. Over 300 ft. of work has been done on the vein which follows the serpentine contact.

SISKIYOU COUNTY

Title to the Azalia and Fern Leaf claims has been granted to Reeves Davis and Henry C. Howard, who were being sued by A. E. Head and Henry Dempsey to obtain possession of the ground. The property is in the Happy Camp district and is crossed by a large vein of gold-bearing ore.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—E. C. Bovie has sold a one-half interest in a group of claims on Lincoln mountain to Schofield & White for $20,000. The same operators have taken a bond and lease on the property of the Homestake Gold Mining & Milling Co., the boud calling for $50,000 and payable in two years. A heavy plant of machinery will at once be purchased.——Large development is in progress at the Blue Ridge property on Columbia mountain. Shipments of smelting ore will be started some time during the present month.——Work is under way at the Hidden Treasure property in East Argentine. Swanson & Johnson, the owners, state that the adit will be driven throughout the winter months.——M. Bonham & Son, owners of the North Star property, brought down a test shipment of two tons of ore this week. Assays show a value of 500 oz. silver and 20 oz. gold per ton.——I. G. McGuire, owning the Black Prince property at Camp Beshears, has interested a number of Chicago capitalists and the holdings will be turned over for a cash consideration of $10,000.——A carload of smelting ore was sold last week by the Burleigh Mining & Milling Co., operating a lease on the Pelican level to the east of the Perdue shaft. Settlement was effected at the average rate of 335 oz. in silver per ton.——Frank Graham, operator of the Scotia mill, shipped 15 tons of lead ore last week that milled 40% in that metal and 40 oz. in silver per ton. At the same time 18 tons of 45% zinc was sold, as well as 10 tons of iron. This was the result of a run of 26 days.——Motor cars to be driven by electricity are to be installed at the Central adit. The adit is in nearly two miles, while laterals have been driven to the Shafter, Lake, and Kentuck veins.

Georgetown, September 17.

GILPIN COUNTY

(Special Correspondence).—H. Boellert & Co. have taken a lease on the After Supper mine at Black Hawk. Water is now being raised from the 250-ft. shaft. It is proposed to start driving from the 100 and 250-ft. levels.——A shipment of 16 tons of ore from the lease being worked on the Pewabic mine by Joseph Reese brought a settlement of 4.50 oz. gold, 6 oz. silver, and 11% copper.——A lease has been granted to Gundy & Co. on the West Pewabic mine. The shaft that is down 140 ft. is to be sunk another 60 ft.—— George R. Steuart is installing a water system in Russel Gulch and Nevadaville.

Central City, September 17.

BOULDER COUNTY

Development that has been in progress for several years at Eldora has recently resulted in the opening of orebodies from which continuous shipments with large earnings may be expected. Just south of Eldora, and extending from Spencer mountain to the Continental Divide, is a strip about half a mile in width and five miles in length that has produced quantities of high-grade telluride ores from surface workings. The recorded production from the Enterprise shaft, 400 ft. in depth, has been $150,000. As depth was reached, however, the inflow of water became so great that further operations through the shaft were unprofitable. To provide drainage and to eliminate hoisting, the Swarthmore adit was started. At a distance of 1600 ft. from the portal and 1000 ft. below the surface, this adit has cut an 8-ft. vein, one-third of which is milling ore averaging from $25 to $26 per ton, while an 18-in. streak gives returns of $936 per ton, principally gold. After raising 600 ft. to connect with the shaft, the manager, H. H. Carpenter, expects to put 50 men on production. The property is equipped with a 350-hp. plant, driven by water power, and the portal of the adit is adjacent to the tracks of the Denver, Boulder & Western Railway.——At the Lost Lake, in the same telluride belt, an adit cut into pay-ore last March, and the property, under the management of Wilson Davis, is shipping $40 ore.——The Highland Mary adit, on the Revenge, another neighboring property, will probably reach the vein within the next 200 to 300 ft. H. W. Brougher is the manager.——At the Fourth of July, which is opening a vein 250 ft. wide, farther up on the Divide, the manager, W. A. Brooks, is putting in diamond-drills to prospect for ore-shoots.

GUNNISON COUNTY

Arrangements have been perfected for the construction of a wagon-road from the Crested Butte & Gunnison branch of the Rio Grande system to the Star mines in the Italian Peaks district. This road will open a rich belt to development as it covers a territory between the old Montezuma and Doctor mines. As soon as the work is completed teams will be started hauling from the Star mine in which a large amount of ore assaying 40 to 60% lead is blocked out.

LAKE COUNTY

The opening of a shoot of high-grade ore on the 750-ft. level of the No. 3 shaft on the Little Johnnie property, at Leadville, has stimulated prospecting near that ground and a number of lessees are opening new territory.——The Across the Ocean shaft is down 212 ft. and at this point cross-cutting has been started to open the ore.——An electric hoist has been installed at the Rattling Jack and active prospecting is under way.——The Little Ella is now being operated through the Yak tunnel as it was found too expensive to handle the ore through the shaft.——Supplies for the re-timbering of the shaft of the Great Eastern mine on Prospect mountain are being taken to the mine

and the first 200 ft. of the ground will be put in good condition this winter.

SAN MIGUEL COUNTY

A group of Denver and Colorado Springs capitalists have organized a company to take over the Suffolk group at Ophir, and will reopen the mine which has been idle for the past twenty years. The ground was located in 1878 and proved rich from the surface though in the later days of the operation of the mine a leasing system prevailed which resulted in the extraction of all the high-grade ore with no development work. It is believed that the sale of this property will lead to an increased activity in this district which has been somewhat neglected by mining interests recently.

TELLER COUNTY

Development on the Chicken Hawk property on Guyot hill in the Cripple Creek district is resulting in an increased production, and it is expected that a carload of ore per day will soon be forwarded from the mine. The present output amounts to 500 tons per month. Two shoots are opened in the lowest levels on which the stopes show a width of two and four feet respectively.——About 40 cars per month of ore that assays $30 to $200 per ton are being stoped on the 1000-ft. level of the Strong mine.——The Union Leasing Co. is shipping a carload of ore per day from the Gold Dollar mine which it is operating under lease.——A powerful electric hoist has been installed at the shaft on the Forrest Queen mine and the lower levels of the claims will be thoroughly prospected for the shoots that are believed to traverse the ground.——The orebody recently opened by Crooks & Co. on the ninth level of the Ruby property on Bull hill is reported to be improving with development, the face showing a width of three feet. A carload of screenings shipped a few days ago is expected to average $80 per ton.——The General Leasing Co., operating at a depth of 300 ft. in the Jack Pot property, is preparing a shipment which it is believed will net the company $50 per ton.

MISSOURI

SAINT FRANCOIS COUNTY

The Eastern Lead Co. has taken over its option on the J. Day land, near Desloge, and has started sinking the shaft, which will be about 400 ft. deep. George K. Williams, former mine inspector, is in charge.

IRON COUNTY

It is reported that the Puxico Iron Co. has leased Pilot Knob and Iron Mountain from the Big Muddy Coal & Iron Co., and will begin opening the old stopes and developing new orebodies at once. Several drill-holes have cut 50% ore. P. J. Crawford is president, and William Chauvenet, engineer.

NEVADA

ESMERALDA COUNTY

(Special Correspondence).—During August the Eclipse mill treated 876 tons of ore from the company leases on Tramp Con. The bullion shipments are estimated at about $12,000. In the Eclipse workings narrow stringers of high-grade ore have been encountered at a depth of 500 ft. Excellent milling ore has been found below the Eclipse fault.——The Penn Mining & Leasing Co. is making regular shipments to the Needles smelter, in addition to its ore treated at the Crystal mill. The selected ore assays about $40 per ton.——Ben Chambers has made arrangements whereby ore from his lease on the Original Bullfrog will be treated by the Goldfield Consolidated. All the ore assays over $7.50 per ton.

Ithyolite, September 16.

NYE COUNTY

(Special Correspondence).—Progress on the diamond-drill hole at the 800-ft. level of MacNamara has been temporarily delayed, due to the sticking of the bit at a depth of 320 ft., which necessitates the reaming out of the borehole to that depth. The large quartz vein on the 800-ft. level has been cross-cut 50 ft. without reaching the opposite wall. Extensive work will be undertaken in following shoots in this vein. A Leyner drill sharpener has been installed.——The profitable ore developed in the westerly extension of the West End vein on the 400-ft. level has decided the general manager, S. H. Bradley, to sink the shaft to 500 ft. To facilitate the greater output of the mine and cut operating expenses the cage will be replaced by a two-ton counterbalanced skip and the steam plant and hoist by a 100-hp. electric hoist.——A reported discovery of $500 silver ore in a well defined vein fifteen miles from Tonopah in the vicinity of Silver Glance caused a small rush to the district. Although overestimated, it is a fair prospect.——The stamp-mill at Liberty, fifteen miles from Millers, is about completed and C. R. Olsen has resigned his position with the Desert mill at Millers to take charge of the new plant.

Tonopah, September 17.

NEW MEXICO

SIERRA COUNTY

(Special Correspondence).—A contract has been awarded to Lewis Orear for 100 ft. of sinking in U. S. Treasury shaft No. 1 and for 100 ft. of raising from the breast of

U. S. Treasury Shaft.

north level No. 2 to connect with the bottom of White Eagle shaft No. 1. Work has started and is progressing rapidly. The shaft sinking is for the double purpose of development and water supply, and recent increase in the flow of water in No. 2 level both north and south justifies the expectation that an additional 100 ft. of sinking will supply all the water needed for mining operations and for the proposed mill. When the raise to the White Eagle shaft is finished it will complete the first unit of development at this property and will place the mine in position to supply a 100-ton mill for several years. The top of the big dump shows ore of bonanza grade from the lowest workings. A six-ton run of dump-ore was recently made at the Morrison crusher on the Keystone property in the north end of the district, and it is understood that a considerable portion of the pulp is en route to the office of the company for preliminary mill-tests.——The Silver Monument property, whose operations have been handicapped by lack of water, is again in full operation following recent heavy rains.——Work on the Black Range Reduction Co.'s mill is progressing slowly, most of the workers having recently been laid off. It is announced, however, that the mill will be ready to receive ore in about sixty days.

Chloride, September 17.

SOCORRO COUNTY

(Special Correspondence).—The reorganization of the Mogollon Gold & Copper Co. has been effected and a letter issued by the president to the stockholders. It is understood the first work will be advancing the east drift from the cross-cut on the Little Charlie and retimbering the shaft on the Cooney mine.——A member of the metallurgical staff of Spurr & Cox spent a week in camp with the general manager of the Socorro mines, experimenting with a view to increasing the saving now being made in this mill.——Concentrate for the week at the Ernestine amounted to 44 sacks, from 435 tons of ore crushed. Development of the seventeenth level west is being pushed. As soon as the accumulation of ore from the different raises in the adit-level can be removed, the main adit will be extended farther into the top ground. A survey has been completed for the pipe-line from a point about one mile above Mogollon to the pumping station. This line will furnish a permanent water supply for the plant as well as reduce the power consumed in pumping to the mill.——Work in the Deadwood mines has been temporarily discontinued, all efforts being concentrated on mill construction. Three carloads of machinery and supplies arrived during the week.——The cross-cut at bottom of winze of the Enterprise Mining Co., below the second level, has exposed four feet of good ore. The winze below No. 5 level is in a large vein of low-grade ore.

Mogollon, September 16.

UTAH

JUAB COUNTY

The Colorado Mining Co. paid the regular quarterly dividend of 6c. per share September 20, and Iron Blossom has posted a similar amount to be distributed on the 26th. In the assessment columns are Beck Tunnel, Black Jack, and Uinta Treasure Hill companies, each calling on their stockholders for 1c. per share.——Development has been resumed at the King William property through the 1000-ft. level of the Eagle & Blue Bell and will be carried forward from this point which represents a depth of 1600 ft. in the King William property for some time. When this has been well advanced a drift will be started on the 500 to open that portion of the King William territory.——The ore from the Centennial Eureka mine is now coming to the surface through the Holden tunnel and the gravity tramway which has been in use for about ten years, bringing the ore from the mine to the railroad, is idle. Most of the shops and surface buildings will be moved to the mouth of the tunnel and the men will in the future go to work that way.——The assessment work for the year has been started on the Montana group in the eastern portion of the district.

SALT LAKE COUNTY

New equipment has been added to the Wasatch-Utah mill in the Big Cottonwood district, and five stamps are now dropping on $50 ore. The company has blocked out a large amount of ore and is considering the advisability of installing electric equipment in the plant.

WASHINGTON

STEVENS COUNTY

Development of the tungsten district shows the properties to be in a position to commence a large ore production at any time additional milling equipment is installed. Several tons of concentrate has been sent to the market. Prospecting is proceeding at many points in the field, embracing an area of ten by forty miles, and corporations are being formed for development on a broad scale."——Conrad Wolfle, of Spokane, president and manager for the United Copper Mining Co., operating near Cheweiah, announces that three tons of ore sent to the Granby company's smelter at Grand Forks, British Columbia, netted $685.28, the distribution being 19.81% copper, 347 oz. silver, and 0.18 oz. gold per ton.——The Republic Mines Corporation, controlled by Spokane men operating near Republic, paid its fourth dividend of 1½c. per share, or $15,000, on September 9.

CANADA

BRITISH COLUMBIA

Considerable development is being advanced in the Portland Canal district and good showings obtained on many of the claims. Lack of cement for the machinery foundations has held back the work at the Portland Canal group though the contract on the mine buildings and houses for the men is being rapidly completed.——At the Salmon Glacier the series of open-cuts has shown a body of galena ore with some gold in a silicious gangue.——In addition to the adit being driven at the Rush-Portland work has been started on the Ne Plus Ultra vein.——On the Portland group the vein has been shown to be 12 ft. wide by a number of open-cuts and an adit has been started that will tap the vein 150 ft. below the outcrop.——The drift at the Red Cliff is in over 800 ft. and the winze is being sunk in a good grade of ore.——The work at the Surprise consists of stripping the Granite vein the development disclosing an ore that is worth approximately $25 per ton.

ONTARIO

Thirty to forty tons of ore per day is being run through the mill at the Savage property in the Cobalt district, and five drills are kept busy underground driving both directions on No. 3 and No. 4 veins and stoping on No. 3.——New camp buildings, including a power-house, shaft-house, and office, have been completed at the Haileybury Frontier mine in South Lorrain and a compressor and motor installed. A cross-cut is being driven a short distance on the 150-ft. level to pick up the 20-in. vein of ore on which the 3000-oz. shoot was opened.——The Green-Meehan, in North Cobalt, has been leased to E. C. Kingswell who will reopen the property. The dump will be concentrated first followed by underground prospecting.——Two new bodies of ore have been cut at the Beaver both of which will assay in the neighborhood of 5000 oz. silver per ton.

MEXICO

CHIHUAHUA

The directors of the Rio Plata Mining Co. have declared the regular quarterly dividend of 2%. The August production of the mine amounted to 83,114 oz. of silver bullion and concentrate.

HIDALGO

The Compañia Minera Santa Ana y Anexas, of Pachuca, has equipped the property with electric machinery, power being purchased from the Compañia Electrica y Irrigadora and transformed from 6000 to 400 volts. A Wellman-Seaver-Morgan double-drum hoist with a hoisting speed of 700 ft. per minute is a portion of the new installation.——The Compañia Minera Santa Ines, Carretera, has also purchased an electric hoist and motor which will be installed at an early date.

OAXACA

The tube-mill at the Natividad y Anexas that was broken recently has been repaired and the plant is again in running order. It is estimated that the property will now produce $30,000 to $35,000 worth of bullion per month. During August the management shipped 21 bars that represented $22,800, the production for that month.

SONORA

Good progress is being made on the new steel reverberatory building at the Greene-Cananea plant, the frame for the building having been completed and preparations made for the installation of two 1850-kw. turbines. The building to house eight new McDougalls is completed and the foundation for the machinery installed.——The old shaft at the Cananea-Boston has been cleaned out and a 3½-ft. vein of galena ore containing 150 oz. of silver exposed at a depth of 40 ft.——E. G. Brassington, of San Diego, has purchased the Rosario mine in the Pilares district and will commence shipping ore about the end of October. A shaft is now down 100 ft. opening a silver-copper ore and this will be continued to the 200-ft. level with drifts started on both levels.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. F. Ferrier is expected from Toronto.

Charles J. Hutchinson has gone to New York.

Frank H. Probert has gone to Portland for a week.

J. Nelson Nevius was in San Francisco going to Oregon.

George S. Rice was in Chicago on his way to Los Angeles.

Arthur G. Blake has left San Francisco for Nome, Alaska.

J. A. Holmes will attend the Mining Congress at Los Angeles.

E. N. Skinner, of New York, was at Reno on his way to Arizona.

J. W. D. Moodie, of Los Angeles, is in New York on business.

John G. Worth, of Denver, is at Reno, Nevada, returing from Ely.

J. B. Farish left San Francisco for Denver and New York this week.

E. F. Burchard is at Portland and will be in San Francisco October 10.

E. L. Porch has just returned to San Antonio, Texas, from northern Mexico.

J. B. Stewart will go to Nicaragua early in October to examine the Luna mine.

Oliver B. Finn has moved from Portland, Oregon, to Coatesville, Pennsylvania.

E. W. Parker was in San Francisco on his way to the Mining Congress at Los Angeles.

S. E. Bretherton is in Los Angeles attending the meeting of the American Mining Congress.

William R. Jewell has been examining mining property in Mariposa county, California, for Bakersfield capitalists.

Alexander P. Rogers is in San Francisco for a few days on his way to New York from a professional trip to Siberia.

W. Murdoch Wiley and Charles S. Herzig are at Elko, Nevada. They have been on an extended trip through the West.

George E. Farish, who has spent the summer examining placer ground in Alaska, is now on his way to Durango, Mexico.

A. S. Howe, of the Constant-Herzig Co. staff of engineers, is making an examination of placer ground in Madison county, Montana.

Charles S. Herzig, president of the Constant-Herzig Co., has been appointed consulting engineer of the Jumbo Extension Mining Company.

Roy H. Allen has returned from Massachusetts to Mexico, where he is manager for the Sierra Plata Mining Co., at Villa Escobedo, Chihuahua.

Walter H. Bunce resigned as manager for the Hercules Con. M. Co. at Silverton, and is now general manager of the Sunnyside mines and mills of the John H. Terry Estate.

H. Foster Bain, Corey C. Brayton, E. H. Benjamin, F. W. Bradley, S. B. Christy, Francis Drake, L. A. Greene, C. W. Merrill, M. L. Requa, and Sumner S. Smith will be among those attending the meeting of the American Mining Congress at Los Angeles next week.

H. A. Megraw will establish an office as consulting engineer at San Luis Potosi, Mexico, on October 1. He has been appointed consulting engineer for the Cia. Minera Angustias, Dolores y Anexas, the Cia. Minera y Beneficiadora Ojo de Agua, and for a private company at San Luis Potosi.

Company Reports

AMERICAN SMELTING & REFINING CO.
AMERICAN SMELTERS SECURITIES CO.

The recently issued annual reports of these companies should be gratifying to stockholders. The former company's report shows net earnings of $7,507,916 for the year ending April 30, 1910, although this was a decrease of $204,063 from that of the previous year. During the year $461,638 was spent on new construction and improvements, leaving $7,046,278 for distribution in dividends. After deducting $3,500,000 for preferred dividends, $3,546,278 was available for dividends on common stock. The Smelters Securities company report shows a net earning of $5,202,310; being a gain of $1,575,884 over that of the previous year, equivalent to about 45% and increasing the surplus by $1,133,425, which gives that concern a total surplus of $1,688,197. The A. S. & R. Co. owns $17,000,000 of the common stock of the Smelters Securities company, which makes its equity in the final surplus of the latter $650,000, or 1.3% on the common stock of A. S. & R. Co. The Smelters Securities company has been a heavy borrower from the A. S. & R. Co. for working capital. The latter has closed, and practically abandoned many of its plants, though over $9,000,000 has been expended the past eight years in new construction and writing off depreciation of the operating plants. The rate of charge for depreciation the past three years is low; being but about 0.5% per annum. As indicative of the increasing volume of business of the A. S. & R. Co. is the fact that its working capital has been steadily increased. In 1904 it was $19,233,834. In 1910 it had grown to $28,014,482. A comparison of its annual net earnings during the years 1900 to 1910, is interesting.

NET EARNINGS

1910.....	$7,507,916	1904.....	$7,905,572

WAIHI GOLD MINING CO.

The annual report from this great New Zealand mine for the year ended December 31, 1909, has just been received. During the year 416,813 tons of ore were treated, yielding in gold and silver £959,593 18s. 11d. To this amount was added £10,439 16s. 4d., being interest on investments, which brought the total receipts to £970,033 15s. 3d. Expenditures were £363,851 10s. 3d., leaving a gross profit of £606,182 4s. 8d. There was carried forward from the previous year a balance of £28,353 1s. 6d., making a total of £634,535 6s. 2d. There was set aside for new machinery and betterments £36,151 7s. 7d. in addition to which 10% was written off for depreciation of plant, being £36,963. The directors also provided £40,778 17s. 6d. toward the Hora Hora hydroelectric scheme. Dividends to the amount of £396,725 12s. were paid during the year, being about £24,000 greater than the amount paid the previous year. From the surplus a bonus of 18s. per share was ordered paid. The mine report states that there remained in sight in the mine 1,335,586 tons of ore in addition to a large amount in pillars and arches which will, in time, be extracted. This, without further development, indicates over three years' ore still in sight in this great property.

TEWKSBURY AMALGAMATED GOLD DREDGING CO.

The annual report of the Tewksbury Amalgamated, of Australia, for the year ended August 30, 1909, shows that during the year 1,181,609 cubic yards of gravel were dug and sluiced by the dredges. The amount of gold recovered was 2.746d. per yard, at a cost of 1.758d. per yard. The profit above working cost was 0.988d. per cubic yard.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

G. H. M., Santa Cruz, California: Basalt with chalcedony in amygdules.

E. E., Alleghany, California: Massive pyrite with earthy brown limonite.

L. C. W., Huizopa, Mexico: No. 1, a fine grained syenitic rock with minute specks of hematite; No. 2, metarhyolite.

J. F. S., Detroit, Oregon: No. 1, quartzite with pyrite; No. 2, quartzite with pyrite and chalcopyrite; No. 3, quartzite with crystals of black chalcocite, brass yellow chalcopyrite, bronze brown bornite, and brownish grains of sphalerite.

COMMERCIAL PARAGRAPHS

The American Well Works, Aurora, Illinois, is represented in the West by agencies at the following addresses: 70 Fremont street, San Francisco; 341 South Los Angeles street, Los Angeles; 1245 First Avenue South, Salt Lake City.

The Edmund T. Perkins Engineering Co. has been organized with offices at First National Bank building, Chicago, for the purpose of examining, constructing, and reporting upon engineering work, especially for irrigation purposes.

The Automatic Gold Separator, Ltd., of Los Angeles, claim to save all of the free gold contained in any siliclous ore. By free gold they mean any gold that can be made free by fine grinding. To prove their statement they have installed a complete reduction plant, including their amalgamator and an 8-ft. Hardinge pebble mill. They will be glad to demonstrate their claims during the Mining Congress, at their plant, and arrangements can be made at their city office, 718 Broadway Central building.

European consumption of copper for the seven months ended July 31, 1910, is figured at 175,136 tons and was larger than for any like period for the last three years excepting 1908, when consumption amounted to 181,774 tons. Consumption in England was but a few tons less than in 1908, while in Germany—figures for which are available only for six months—it was slightly in excess of 1908. In detail the figures for the period for the past three years are as follows (in tons):

	1910.	1909.	1908.
England (7 months)	46,163	39,114	47,080
France (7 months)	32,587	34,758	36,933
Germany (6 months)	79,447	77,919	79,090
Other countries (7 months)	16,939	17,890	18,671
Total	175,136	169,681	181,774

TABLE OF CONTENTS

EDITORIAL

A pleasing evidence of journalistic enterprise is found in the special edition of the *Los Angeles Mining Review* issued during the session of the Mining Congress.

THE proceedings of the American Mining Congress now in session at Los Angeles are of unusual interest and will be reported in full in the issue of October 8.

SCHEFTELS & CO., Broad street, New York, brokers were raided by the Federal authorities on the morning of the 29th ult. for conducting a 'bucket-shop' business. All of their offices in other cities were likewise simultaneously raided, according to a late special despatch to the *Mining and Scientific Press.*

ON the Comstock Lode at Virginia City, Nevada, reports of new development in the deep levels of some of the central mines are of encouraging nature. Indications are that large bodies of ore may be found in hitherto unexpected places, at and near the contact of the great diabase dike with the hanging wall andesite.

THE importance of the mineral industry in the Joplin region of southwestern Missouri is not generally realized throughout the mining regions of the West. The monthly output of zinc and lead ores from that part of the country is at present at the rate of nearly $15,000,000 annually, not by any means an unimportant contribution to the aggregate output of the United States.

PAPUA, or New Guinea, is the latest country to threaten additions to the troubles of those who would control the copper output. Lodes 20 to 90 feet wide consisting of soft sulphide ore assaying 8 to 30 per cent copper are reported and one operator on the Laloki river cleared $10,000 in six months, when the grade having fallen to 8 per cent, it no longer paid to ship the ore.

MEXICO celebrated most enthusiastically the close of her first century as an independent nation and the whole family of nations was glad to extend hearty congratulations and good wishes, for the Mexican government has been happy in its conduct of foreign as well as internal affairs. An excellent account of the *fiesta* as well as an elaborate summary of the resources of, and present conditions in, the country is given in the anniversary number of the *Mexican Herald.* One interesting and noteworthy in-

eident of the celebration was the founding of a National university. Mexico already had many excellent schools but, like the United States, heretofore lacked a great central university to crown the system. While conditions in the two countries differ materially, it is far from certain that we would not do well to follow in this the example of our southern neighbor.

INCREASING activity in drift mining enterprises in California is noticeable, particularly in the northern counties of the State where there are hundreds of miles of ancient gold-bearing rivers that are still intact and of which little is known, further than that they are there. Mines of this description usually require less capital for their equipment than quartz mines, and some of the most profitable ones of the State have been of this kind.

DULL documents tell but half the story of geological survey life, and for the benefit of the younger generation who should know how the men they now admire as leaders got their start, we picture this week something of the other half of the story. The scenes of life on the Second Geological Survey of Kentucky are typical; the exceptional thing is that an artist was at hand to so faithfully present them. If any of the members of the party or their friends think such intimate scenes not proper to publish, we can only say, as did the Editor of the improper number of *Life*: "You should see what we haven't published."

IN this issue we publish the third and concluding article of a series on slime treatment by Mr. Edwin A. Sperry. The material embodied in these articles was originally used by Mr. Sperry in lectures at the Colorado School of Mines. Later, in a slightly different form, it was published in the *Western Chemist and Metallurgist*, the attractive monthly journal of the Western Association of Technical Chemists and Metallurgists. Acknowledgment should have been made to this Society with the first rather than the last of the series but was inadvertently omitted. This lively little Society has so many good things to its credit that it can well afford to be generous. Mr. Sperry has admirably treated the problems of slime concentration, supplying that broad review of the general field which from time to time affords the best basis for advance. In connection with his articles the recently issued bulletin of the Geological Survey in which Mr. H. E. Ashley has discussed the properties of colloids, may be read with interest. Our readers will remember Mr. Ashley's illuminating article on the subject that we published last year.

GEOLOGICAL SURVEYS have so far been conducted by the several States in Australia. It is now proposed to organize a Federal survey to study the resources of the Commonwealth as a whole and the arguments for and against the proposal are reviewed in *The Australian Mining Standard*. It is entirely true, as pointed out by Mr. E. J. Dunn, director of the Geological Survey of Victoria, that the expense of the work would fall on the richer States out of proportion to their area. The excellent work already done by existing organizations is well recognized abroad as well as in Australia and as Mr. Dunn points out, Victoria is abundantly able to complete the work within her own borders. The matter will doubtless be settled to the satisfaction of the Australians, the ones most concerned, but we will be pardoned, we hope, for suggesting that in America, where somewhat similar conditions have obtained, the United States Geological Survey has abundantly justified its existence entirely aside from the enhancement of the value of the public lands, resulting from its work. It is quite true that the Eastern States have furnished most of the money while the surveys have been mainly carried on in the West. Development of the West, however, has been of the largest possible and most direct financial benefit to the Eastern States and people. No one doubts that in the unsurveyed and even unexplored parts of Australia great resources lie dormant. Their development would help every State in the Commonwealth and a rich, populous, and prosperous Australia would make for the greater peace of the world. It is always true that the States and territories that most need geological surveys are least prepared financially, to conduct them, and in America we have found it an excellent plan for each State to maintain such organization as its funds would permit and for the Federal government to supplement the work of the State officers without much regard to political boundaries. The scientific problems of geology are continental and on their solution must rest all local studies. In the nature of the matter therefore, as well as in its economies, there is a reason for the larger organization.

Mine Inspection

One of the most important matters that will be presented to the American Mining Congress at its session this week in Los Angeles, will be the report of the committee on the prevention of mine accidents and the adoption of a uniform code of mining laws. Elsewhere herein will be found an outline of the legislation suggested. That the report has been prepared only after the exercise of unusual care is evident. Not only did the committee investigate the mining laws of the several States, but they also studied those of foreign countries. The effect of the operation of the laws was also studied. The draft of the proposed law is necessarily tentative. It is offered as a suggestion, or rather as a model along the lines of which the several States may each formulate their own laws governing the equipment and operation of mines. It will inevitably be criticised as being too comprehensive and too complex but for the purpose in view, education of the public and stimulation of interest, comprehensiveness is not a fault. It is well, also, to remember that the subject itself is complex and the difficulties can not be solved by a 'simple rule of three.'

All of the Western mining States have mining laws, and some of them have official mine inspectors, but there is entire lack of uniformity, and in some of the States laws for the protection of the working min-

ers are conspicuous by their absence; or, if appearing at all on the statute books, only nominal penalties, or none at all, are provided for their infraction. During its investigation of this important matter the committee had figures prepared by an expert statistician, showing the fatalities in metal mining in the United States, and these figures indicate that the loss of life in metal mines is at least as large as in collieries. As the investigation covered only those States having the best systems of mine inspection, and where, in consequence, the fatal accidents were probably less numerous than where there are neither inspectors nor protective legislation, the real number of accidents is probably greater in metal than in coal mines. For various reasons many mine owners and operators are opposed to mine inspection. Ordinarily the objection to the employment of an inspector by the State is represented to be purely commercial in its character—that the more or less frequent visits of the inspector, or his deputies, permit a knowledge of the extent and value of ore reserves to become public, to the disadvantage of the mine owners. This excuse, however, is seldom, or never the real cause of opposition. The actual reason for objection to a mine inspector, or to a code of laws demanding safe working conditions in mines under severe penalties, is found in the increased cost of production under these conditions. The proposed law contains no provision to which legitimate objection can be raised, notwithstanding that an exact observance of its requirements would, at some mines, result in a direct increase in expense. Furthermore, when the matter is considered in its broader light, it will be found in nearly every instance, that where increased expense would result from compliance with the law, there is a compensating advantage in the larger economy of mine operation under the imposed conditions. Take the matter of mine maps, for instance. Any mine too poor to pay for the necessary surveying and accurate mapping of its workings were better closed forever. There are many mines operated without the aid of mine maps, and frequently operations in such mines are suspended, the property is flooded with water, and remains idle for years. Should it become desirable to reopen such a mine, correct maps of the old workings would have a value far in excess of their cost. There are scores of examples of the great expense resulting from the failure to provide maps of the mine workings when they were accessible. In the matter of explosives, also, it may be noted that seldom, if ever, has it been really economical to store large quantities of high explosives in mine workings. There are too many instances of accidental explosions of underground magazines. The proposed law seeks to stop such underground storage; which is a humane and businesslike move. Some mine managers believe in getting all the wear possible out of a winding rope, but it is rare that hoisting ropes are continued in service after they are known to have outlived their usefulness, and to be no longer safe. Those accidents due to breakage of ropes are more commonly caused by over-winding, or jamming of the cage, or skip, in the shaft, though occasionally breakage results directly from deterioration of the rope, and this can, in a great measure, be obviated by competent rope inspection. There is not a uniform code of mine-bell signals, though the advantage of having such code is obvious. One of the most important provisions in the proposed code is that requiring two openings connecting the main workings with the surface. There are large and profitable mines in the Western States having only a single shaft, or reached through one adit, or main gangway, notwithstanding that there are, as suggested by the committee, laws on the statute books requiring two openings. The fact that the State laws make this requirement is entirely without effect in the absence of a mine inspector, as no other person will take the initiative in enforcement of the law. The sinking of shafts and driving of adits is expensive, and there are those who consider one adit, or one shaft sufficient for all practical purposes, and only are willing to sink or drive another when required by the increased output of the mine. It is far from certain, however, but that even the extraordinary expense of a second opening, connecting the main workings with the surface, is a benefit rather than an unnecessary and enforced extravagance. In deep mines which are provided with but one shaft, the ventilation is notoriously bad. A second shaft connecting by the various level workings with the original opening would work a wonderful improvement in the ventilation, with a corresponding increase in the efficiency of the workmen, and in a mine employing 100 men, or more, underground, an increase of as little as 10 per cent in the efficiency of the mining force would in a few years more than cover the expense of an additional shaft, giving no consideration whatever to the advantage such shaft would possess as a means of escape in the event of an accident.

There is an existing and constantly growing sentiment in favor of a code of mining laws for metal mines which shall more completely safeguard the health and lives of miners underground, notwithstanding that many mine managers object, and have actively opposed every attempt to pass such a code of laws, or to the appointment of mine inspectors, in some of the Western States. We appreciate that the changes proposed will involve expense and may be disastrous at first to many legitimate enterprises. We believe though in inspection, as indeed do all thoughtful operators who are convinced that honest and fair inspection is possible. To assure such inspection should be the first concern of all interested in the mining industry and it may be remarked that experience elsewhere has shown that when the operators make no move toward establishment of a proper mine inspection service, the men sooner or later secure the enactment of a law with some such absurdity as in Oklahoma where the Inspector is an elected officer. In Arizona a commission was appointed that thoroughly studied the matter and recommended an excellent code. This seems to us a sensible method of approach. To such a commission the report of this committee would be of the highest utility, and to the general mining public it will be informing and educational.

Concentration of Slime—III

By Edwin A. Sperry

(*Continued From Page 211*)

FINAL TREATMENT

It is with some delicacy that the subject of the final treatment of slime is approached, as there will appear in the discussion many facts which may be taken as an argument in the defense of the slime concentrating table which bears my name.

The line I shall take up will be, as nearly as possible, the abstract discussion of the principles involved in the construction and operation of various forms of concentrators used for this special purpose and the comparison of them from a practical as well as from a technical point of view. The purpose is to briefly review the previous statements and take up a few of the salient points, the more clearly to demonstrate the vital necessity of proper preparation of the pulp before concentration is attempted. The advantage of using the spitzkasten for the purpose of preparation has been emphasized already. An attempt was made to show the various actions of settling, classification, partial concentration, and dewatering which are carried on simultaneously, as well as the special value of each in the proper preparation of the pulp for its final treatment. In comparison, instances were given in which, by the use of canvas tables, these advantageous results were not only in a measure lost, but that other conditions resulted that tended to endanger if not entirely prohibit good results in the final treatment. Another point emphasized was, that in any current whatsoever, losses are sustained. This radical statement was modified to the extent of an admission that in a very slow forward movement of a large body of water, a settling action is promoted that more than compensates for the slight loss which is inevitable.

Still another point dwelt on was that in the final treatment of slime, and it might also be added, in any process of concentration in which water is used as a conveying medium, the greatest possible consistency should be given to the pulp, compatible with complete stratification. In some characters of ore this consistency may be made greater than in others. For instance, clayey or porphyritic ores cannot be properly stratified at as high a consistency as can ores of a quartzose nature. While the former should not exceed 15 to 18% solid consistency, the latter may reach as high as 25 or even 30 in some cases. The point must be determined by experiment and no fixed rule can be laid down. In the discussion of the various forms of machines used for the purpose of slime concentration, one radical point has been assumed. This is that as a slime particle has very little or no ponderosity, any table or machine that depends on propelling these very minute particles across its surface by the aid of their inertia through using a bump, a reciprocating motion, or any similar method, cannot, from the nature of things, be classed as a slime table. The surface itself should have a continuous progressive movement conveying the pulp, which rests motionless upon it, through the various stages of stratification, washing, separation, and final cleaning of the surface. This is in direct compliance with the principle that in handling slime all disturbances must be most strictly avoided. It might seem inconsistent to state at this point that a vanning motion of some kind can be applied to the surface with a decided advantage to the results, both as to capacity and to efficiency. This seeming contradiction, however, can be readily harmonized by the statement that as soon as the slime particles are deprived of their liberty of action and are hemmed in and jostled by their neighbors they have less of an inclination to escape. In other words, when the pulp is dewatered to a high percentage of consistency, this very consistency, in direct proportion to its degree, allows of agitation without loss. It is because of this fact that in final treatment, the greatest possible consistency compatible to perfect stratification should be given to the pulp. However, even with high consistencies, a too violent disturbance should be avoided. Just enough motion should be given to keep the pulp 'alive' and give it an opportunity to stratify but not enough to mix it. This is a point which is so often lost sight of by some who think that "if a little is good more is better." The character and effect of different forms of motion will be taken up under the proper head.

There are three radical types of tables used for the purpose of concentrating slime, classified as follows: (1) the conical buddle, (2) the end-moving belt, (3) the side-moving belt. In the first can be placed the Evans, the Roberts, the Cornish, and the Sperry buddles; in the second the Frue, the Embry, the Golden Gate, and the Johnston vanners; in the third the Luhrig, the Monell, the McCoy, and the Roberts slime belts. There are a number of modifications and combinations of these types, for instance, in the A. & E. slime table which, having features common to two or more of them, can hardly be classed as one of radical type. In the discussion and comparison of the several forms of machines the subjects will be divided into: (1) the general forms, (2) the character of the different pulp distributions, (3) the efficiency of the different forms of motion and degree of consistency of the pulp, (4) the character of the separation on the different forms of machines, (5) the character of the products, (6) capacity, (7) efficiencies, (8) general discussion. In these comparisons typical machines will be selected: (1) the buddle, to which a circular vanning motion has been recently applied; (2) the Frue vanner, which is too well known to need any description; (3) the Luhrig belt machine, which was one of the original machines to adopt the side-moving belt. In referring to them only simple mention will be made.

(1) **General Form.**—The buddle is a low conical table, circular in form, with a surface which slopes uniformly from the centre to all points of its edge. It revolves slowly on its centre and has a quick circular vanning motion in an opposite direction to its revolution. The vanner is an endless belt, having a surface oblong in form, with a uniform slope in line with the greater dimension. It has a slow uniform progressive motion in line with its greater dimen-

sion, from the lower to the higher end and a quick uniform reciprocating motion transverse to the slow progressive motion. The Luhrig is an endless belt having a surface oblong in form, with a uniform slope transverse to its greater dimension. It has a slow intermittent progressive motion in line with its greater dimension which is supplemented with a slight knock or bump to assist in action of stratification.

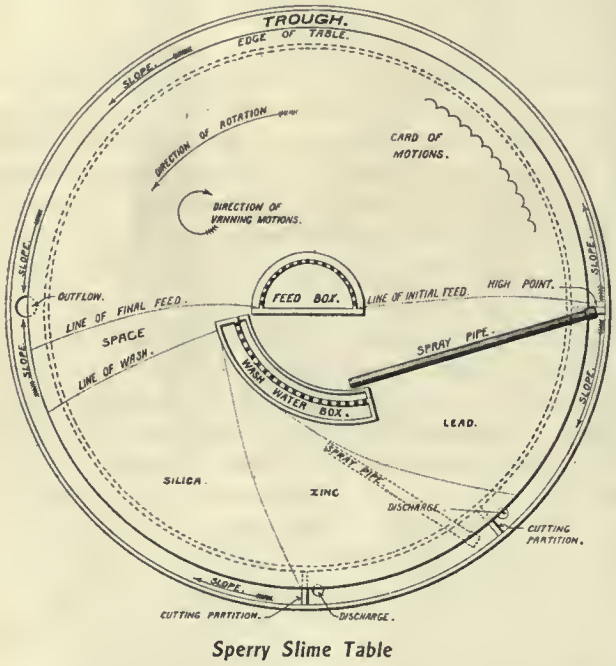
(2) **Character of Pulp Distribution.**—On the buddle the pulp is delivered at the centre and assumes a fan shape which, in broadening, naturally decreases the depth of the flow, thereby retarding its speed. On the vanner the pulp is applied across its entire width near the higher and flows uniformly to the lower end. The sectional area being uniform at all points of the flow, its speed is practically uniform, with possibly a slight acceleration near the lower end. On the Luhrig the pulp is applied at the upper edge of the belt near the end from which it moves and flows across it, assuming slightly a fan shape. In comparison, the fan-shaped flow and the consequent retarding of the speed, is obviously of advantage in the arresting of the slime particles, giving them more chance to settle to the surface of the belt.

(3) **Efficiency of the Different Forms of Motion and Degrees of Consistency.**—A number of tests have been conducted to ascertain the relative efficiency of the circular as compared with the simple reciprocating motion, as regards the degree of pulp consistency possible for the most satisfactory results. In every case it was found that the circular motion was capable of stratifying pulp of nearly twice the consistency of that which could be properly treated by the simple reciprocating motion. To be more exact, while the pulp fed to the vanner contained, on an average, 15% solids, that fed to the buddle carried 25%. In each case the consistency was about at the normal. With the Luhrig a much higher consistency can be maintained than on the vanner. The buddle and Luhrig more closely resemble each other in this regard. To explain: the pulp as it is fed on the vanner, across its width near the upper end, flows directly to the tail of the machine. This feed being continuous, the pulp must be sufficiently dilute to flow freely and not cake. During the flow from one end to the other the reciprocating motion of the machine is depended upon to stratify the pulp and bring the mineral particles in contact with the belt surface. These, by the travel of the belt, are carried back, up the slope of the surface directly in the face of the flow and passing over the upper or head end of the machine, are washed off into their proper receptacle. In the case of the buddle as well as of the Luhrig, the pulp is fed on the surface at the highest point. As it flows out on the surface it is spread out, and, in the case of the buddle, is allowed to rest. In the Luhrig it has not the same degree of opportunity to stop in its course, but certainly is not compelled to battle against a current moving in a direction opposite to the motion of the surface. After the pulp has been thus distributed, on the buddle as well as on the Luhrig, it is conveyed from the zone of feed flow and, by the motion of the surface itself, is passed through the various stages of operation as before stated. As the flow of pulp on these two machines can be retarded to advantage, it is self evident that the degree of consistency is only limited by the efficiency of the motion employed for the purpose of stratification.

(4) **Character of the Separation in the Different Forms.**—Owing to the form of the vanner, the separation of the mineral from the gangue is largely regulated by the application of the washing water, assisted by the use of some of the mechanical adjustments. As there are two separate points of discharge, the head and tail, the products are therefore either concentrate or tailing, without any possibility of intermediate grades. With both the buddle and the Luhrig all discharges are made over one continuous edge. The tailing near the lower edge is first discarded, after which the mineral or concentrate is washed off. In some cases the distinction between the two products is well marked, but ordinarily there is some merging. As a result of these conditions the possibility of cutting out various products is denied the vanner, while on the buddle and the Luhrig such divisions are readily made. While it must be admitted that the tendency toward merging prevents clean separation, especially when two minerals such as lead and zinc sulphides are being treated, still the possibility of cutting out as middling that portion included in the zone of merging, for the purpose of re-treatment, more than compensates. In this manner clean products can be obtained. In one case where a separation between pyrite and silica was made, a clean concentrate was cut out on the buddle. A middling product was also cut out between the concentrate and the tailing which was returned to the circuit and handled with the original pulp on the same machine. The product obtained ran 34% iron and 6½ silica, as against 29 iron and 18 silica in the product obtained from the other tables. These results total each in iron, sulphur, and silica 88% approximately, which indicates that there was some other element present, presumably zinc, in the form of sulphide. This advantage cannot be lightly passed over.

(5) **Character of the Products.**—This particular feature has been given considerable study and in its analysis, the particular claim of any machine, as to its being especially adapted to the concentration of slime, can be readily established or disproved. In all ores treated by concentration the mineral particles between 100 and 200 mesh will almost invariably vary in value from those which will pass a 200 mesh. In some cases it has been found that the finer size was higher in grade; occasionally the reverse is true. In one case in a slime carrying copper, the fine mineral particles were much lower in value than the coarse. In this case a buddle was being operated in a competitive test beside the vanner. By careful examination the following conditions were found to exist: the product from the buddle contained a large proportion of slime mineral; the silica content was practically the same in both products; a larger quantity by weight was produced by the buddle; the product of the vanner ran 23% copper

as against 18 in the product from the buddle; the total copper was greater from the buddle; and finally, the tailing from the buddle ran noticeably lower than that from the vanner. Analyzing the conditions, it is clear that the presence of a larger proportion of slimed mineral in the buddle product, which at the same time ran lower in copper and practically the same in silica, indicated that the finest of the mineral was lower in grade than the coarser; the fact that the tailing from the buddle ran less in copper than that from the vanner indicated that the buddle made a closer saving, and this, coupled with the facts that the quantity of concentrate was larger from the buddle and contained a larger proportion of the slimed mineral, proved conclusively that the buddle was a better slime saver than the vanner. There are several lines of deduction which might be reasoned out, but these are sufficient to make clear the first statement, that a study of the character of



Sperry Slime Table

the products will readily prove or disprove the claim made for any machine as to its qualities as a slime concentrator.

(6) **Capacities.**—In the matter of capacity the types can be named in the following order, based on each foot of width: (1) the buddle, (2) the Luhrig, (3) the vanner. From experience with the three types the following figures of capacity have been deduced. They may be safely used for approximations: for the buddle, with a circular vanning motion, from 2 to 3 tons for each foot of radius; for the Luhrig, 1½ to 2 tons for each foot in width, and for the vanner, 1 to 1½ tons for each foot in width. These are all based on 24 hours running. This would give a 10-ft. buddle from 10 to 15 tons, a 3-ft. Luhrig from 4½ to 6 tons, and a 6-ft. vanner from 6 to 9 tons in 24 hours. The original Luhrig tables had belts 3 ft. wide, and it is fair to suppose that an increased capacity could be obtained by using a wider belt. The Wilfley slime table, which is a combination of the Luhrig and the vanner, has a much greater width, though the capacity is not increased proportionately. In analysis of conditions we can find a cause for these varying capacities. It will be noted that they are about in direct proportion to the normal consistencies of the pulp, as discussed under that head.

(7) **Efficiencies.**—A few statements of results of actual work as practical illustrations of some of the previous statements are here given. In one case, where the three typical machines were operating, the results were as follows. The buddle had a capacity of 10 tons, consistency 25% solids, concentrate 34% iron, 6½ silica, tailing trace in gold. The vanner had a capacity of 6 tons, consistency 15% solids, concentrate 33% iron, 10 silica, tailing 0.02 oz. gold. The Luhrig type, 6 tons capacity, concentrate 29% iron, 18 silica, tailing 0.01 oz. gold. In another case the buddle had 12 tons capacity, 25% solids, concentrate 47% lead, extraction 67%. The vanner 6 tons capacity, 14% solids, lead 55%, with 39% extraction.

(8) **General Discussion.**—The question may arise as to what might constitute a proper amount of motion. As the result of a number of experiments it is thoroughly determined that in properly stratifying slime pulp, 300 inches of motion per minute is the maximum and that should only be used, either when heavy or clayey gangue is to be separated from a heavy mineral, or when two minerals are to be separated from one another. It is ordinarily the case that over 200 inches per minute are used. In the vanner, for instance, 200 revolutions of the shaft is an average speed. With this speed the throw is from ½ to ⅝ in., making from 1 to 1¼ in. per complete revolution, giving from 200 to 225 inches per minute. In the buddle with ¼-in. circle of motion, 300 r.p.m. would give 235 in. per minute. With ⅜-in. circle at 250 r.p.m. would give 281 in. per minute. These sizes and speeds have been shown to include those giving the most favorable results, and so it can be stated that between 200 and 300 in. per minute will be found a speed which, in almost every instance, will meet the requirements.

In discussing these three types, only such forms have been taken up as might be considered as most commonly used, and what might be called standard or representative. There is another form which might be considered as a fundamental type. It is that using the principle of the pan. This has never proved satisfactory or practicable, as it has never been made automatic and continuous. It was employed in the Copeland table some years ago, but was not successful. The A. & E. slime table, recently introduced, seems to be the most practical application of this principle. This is a combination of the pan and the Luhrig. It certainly presents interesting features. The Wilfley slime-table is constructed on the general form of the Luhrig. So much so, in fact, that it has been considered as a form of this type. It has some features, however, which put it at variance with the Luhrig. The up-throw of the motion, the use of transverse trays, and the method of delivery of the concentrate give it some resemblance to the vanner. With the motion, the tendency is to throw the mineral to the upper ends of the trays against the ascending current.

Early Geological Surveying in Kentucky

By H. Foster Bain

From the time when Rafinesque in 1824, "in only 26 duodecimo pages gave the geological, ethnological, and historical annals of Kentucky from the first day of creation according to Moses, down to the current year," geology has received much attention at the hands of Kentuckians. Geologists even form part of the background of the literature of the 'Blue Grass' State and 'Reynolds of the Geological Corps' is, at least, as important a member of the table group whose conversation John Fox repeats for us, as is the gentleman who contributes to the uplift of the drama by 'carrying a spear in the third act' of the latest Broadway musical extravaganza. Even better claims, however, may be urged for Kentucky

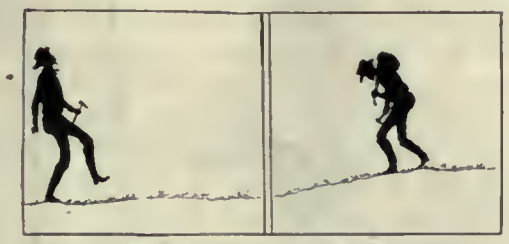


Fig. 1.—7 A. M. Leaving Camp. 7 P. M. Returning Home.

geologists. From 1854 to 1860, the last six years of the life of that pioneer American scientist, David Dale Owen, were spent in organizing and directing the work of the first Geological Survey of Kentucky. With Robert Peter, Sidney T. Lyon, Leo Lesquereux, E. T. Cox, and Joseph Lesley on the staff, it is no wonder that the reports of this early survey are

Fig. 2. U. S. Coast Survey Hunting the Coast.

greatly in demand and largely used today. Beginning in 1860, Kentucky had troublous times, and the attention of its officials and citizens was perforce directed to other things than the cultivation of science. By 1873, conditions were again normal and the need of a more complete investigation of the natural resources of the Commonwealth was felt. Accordingly, a second geological survey was organized. It continued active until 1891 and after an interim was succeeded by the present Kentucky Geological Survey of which C. J. Norwood, himself a son of J. G. Norwood, the pioneer State geologist of Illinois, is the director. The survey organized in 1873 was placed in charge of Nathaniel Southgate Shaler, then professor of paleontology at Harvard College, and long and familiarly known to all Kentuckians as 'Professor Nat.' Shaler must always be considered one of the great figures of American geology. Entirely aside from his scientific work he

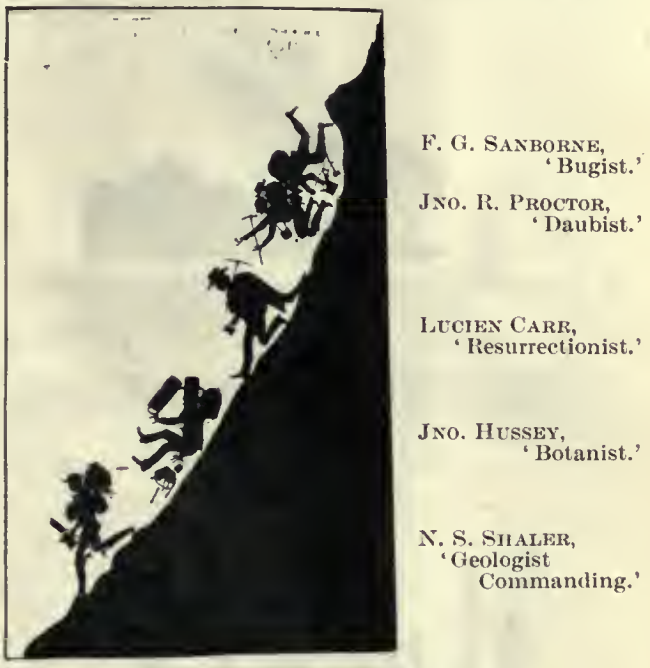

Fig. 3. Moving Camp into 'the Gulf.'

was a man of enormous influence. Through his writings and his work as a teacher at Harvard both before and after his service in his home State, he did much to popularize his favorite science. The indirect influence both on him and on the country of his seven years' official work in Kentucky is difficult to estimate, though undoubtedly large.

Gathering about him a brilliant staff of young men, who in turn became leaders in many lines of professional work, Shaler promptly took the field and began work. The party included A. R. Crandall, P. N. Moore, C. J. Norwood, and J. R. Proctor, as assistant geologists, while Robert Peter had charge of the chemical laboratory. Attached to the geological party were John Hussey, botanist; F. G. Sanborne, entomologist; Lucien Carr, archeologist; W. B. Page and W. W. Beckham, topographers; W. T. Page, flagman; and last, though far from least, big, fat, good-natured Sam Tutt, the cook. For cooks were essential to geological survey work in those days, even in Kentucky. Then, geologists did not travel in Pullman cars, and swift automobiles had not yet made it possible to keep headquarters at the county seat. Indeed hotels were few and far be-

Fig. 4. Getting up Steam.

tween, and most travelers who experienced such as existed were satisfied that they should remain so. Camp life was a necessity in such work. In these degenerate days a race of geologists is coming on that knows nothing of packing, field assistants that

Fig. 5. He Wanted "To See the Mule He Couldn't Drive." He Did.

could not make camp without help, and have never tossed flapjacks high in the air!

Travel and its vicissitudes formed a large part of the daily life of the early geologist. In the sketches presented herewith are scenes that will re-

Fig. 6. Enjoying the Hospitality of the Country.

call old times to many. The reproductions are from silhouettes made at the time by John R. Proctor and carefully treasured since by members of the party. They are published here by the courtesy of Philip N. Moore. Proctor, who succeeded his chief

Fig. 7. Showing a Native the Wonders of Entomology.

as director of the survey and later was called to Washington by Cleveland to become a member of the United States Civil Service Commission, came to look on these little pictures as *infra dig* and in after years neglected what was evidently an especial talent. He would doubtless have been a great cartoonist; but in pre-McCutcheon days making cartoons was not so highly esteemed as a method of molding public opinion as now, nor, it may be added, was skill in that direction so well paid for.

In the first figure the artist has represented the contrast between 7 a. m. and 7 p. m. The geologist is evidently in high spirits when he leaves camp, but by evening the day's work has taken its toll and with his heavy bag of rock he trudges wearily home

Fig. 8. Taking a Sight.

to a late supper. The topographers had their own troubles with transportation as is shown in the second drawing which is variously called 'The Triangulation Party in Action' or the 'Coast Survey Hunting the Coast.' Then as now co-operation with Federal bureaus was in order, and the triangulation work was fitted into the general scheme. The valiant leader of this band of itinerants is William B. Page, whom Coloradoans will recognize by this work in engineering if not by the picture. Following him is W. W. Beckham, now dead, a brother of the recent Governor of Kentucky. (It some way comes natural to mention family connections in writing of Kentuckians.) In the youth carrying the flag at the rear, probably no one will recognize Walter T. Page, now a most dignified director of the American Smelting & Refining Co., and long manager of the Omaha works. He has moved up toward the head of the procession since those days. The name of the fourth member of the party has not been preserved.

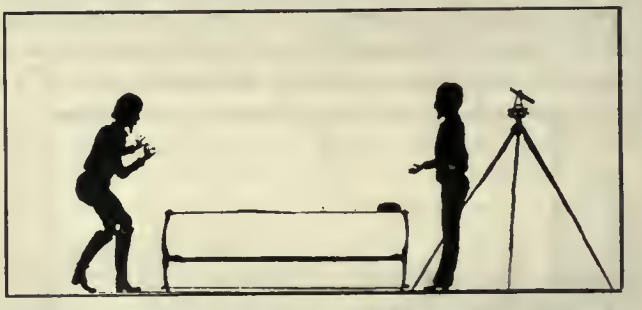

Fig. 9. The Topographer Invents a New Cot Weighing Only 8 Pounds.

Fig. 10. He Decides to Only Warrant It on Level Ground.

Moving camp is always a great event and some-

times involves much difficulty. In the third, fourth, and fifth pictures some early problems in transportation are illustrated. In the first (Fig. 3) the line of march includes, N. S. Shaler, geologist commanding; John Hussey, botanist; Lucien Carr, 'resurrectionist'; John R. Proctor, who modestly labels himself 'daubist'; F. G. Sanborne, the 'bugist' who is helping Proctor along. As the topographers were evidently not with the party at this time we may reserve some doubts as to the accuracy with which the slope has been taken. In Fig. 4, it is evident that the team has balked and the combined efforts of the party have so far proved unavailing. The chief is represented as resorting to the traditional expedient of building a fire under the recalcitrant animal. If it were not for the picture I would doubt this part of the story. In the next quite a different tale may be read. The gentleman who is bracing himself so firmly against the frail dash board is

Fig. 11. The Professor Decides to Sleep Higher Off the Ground.

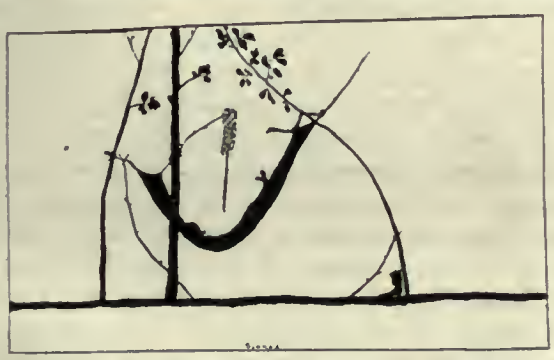

Fig. 12. He Miscalculated the Strength of His Materials.

Philip N. Moore, now the well known consulting engineer in St. Louis, but then beginning as mineralogist of the party. It is said that he carelessly expressed a desire "to see the mule he couldn't drive" and his friends accommodatingly arranged to grant his wish, as a pleasant little surprise.

The natives and their ways form the motif of a number of Proctor's sketches. The mountaineers of east Kentucky are everywhere known as a poor but exceedingly hospitable people. Occasionally this leads to their undoing as in Fig. 6. In this case a hungry geologist, having been invited in for a meal, has eaten an amount that those knowing the present director of the Kentucky Geological Survey would not anticipate, as is shown by the remark of the man of the house: "I declare mister, you've got the powerfulest appetite I ever seen. You've eat up all wee 'uns dinner." In justice to the visitor it must be said that he had no notion that the dinner had been cooked for the whole family. Occasionally, visitors came to the survey camp and then every effort was made to return courtesies. The favorite method of entertainment was to set up a microscope on some convenient stump and show the caller something of the wonders of entomology (Fig. 7). Sanborne was always good at this and would lecture for hours to admiring and awestruck adventurers. Encounters on the road were numerous and occasionally embarrassing, as in Fig. 8, where the mule is

Fig. 13. Nightmare in Camp.

anxiously eyeing Page's theodolite while the fair lady on his back says: "I say, mister, will that thing shoot? Take it away. It skeers my critter."

Trouble follows the surveyor even to his bed as is shown in Fig. 9 and 10. In the first the topographer, Page, is explaining to the admiring artist the construction of his newly invented bed which "only weighs eight pounds." In the second scene the bed is shown in action, and the topographer decides that he will only undertake to warrant it on level ground. The spirit of invention having broken loose Sanborne tried his hand, deciding, as shown in Fig. 11, to swing his bed higher from the ground. Unfortunately, as revealed in the next figure, he

Fig. 14. Home Again—3 A. M.

was but a careless scientist and neglected to calculate the strength of his materials. High beds would evidently have been of advantage as indicated by the thirteenth picture which proves the substantial nature of the night mares that visited the camp.

Even the longest field season comes finally to an end and the geologist goes home to renew acquaintance with his family. In Fig. 14 is shown a touching family scene where at 3 a. m. the weary surveyor has about decided that after all camp life was not so bad.

Uniform Mining Laws

*The committee on Uniform Mining Laws appointed by the American Mining Congress at its Denver meeting in 1906, has completed its labors and presented its report to the Congress now in session at Los Angeles. The members of this responsible committee were Walter Renton Ingalls, chairman; J. Parke Channing, James Douglas, James R. Finlay, and John Hays Hammond. The object of the appointment was the drafting of a code of laws regulating the operation of coal and metalliferous mines which might serve as a model in all of the mining States. It has been felt that if adoption of a uniform law could be brought about it would reduce the number of accidents in mines. The report of the committee and the draft of the proposed law are presented in abstract below.

Since its appointment, the committee has had under continuous consideration the matter with which it was charged. At the meetings of the American Mining Congress in 1907, 1908, and 1909, it reported progress. At the meeting in 1909 it was authorized to present its report not only to the American Mining Congress, but also to the American Institute of Mining Engineers and the Mining and Metallurgical Society of America, and to present its report in printed form during the interim between meetings of the American Mining Congress. The committee collected from State officials copies of their mining laws. With the assistance of *The Egnineering and Mining Journal*, copies of the laws of Great Britain, the Transvaal, New South Wales, Victoria, Queensland, Western Australia, Tasmania, New Zealand, and certain European countries were also obtained. These laws were subjected to careful study. Upon the basis of the existing laws of the States, of Great Britain and the English speaking colonies, a tentative draft was prepared and printed in limited number in 1909, for convenience in securing the advice and criticism of a considerable number of persons engaged in the mining industry. At the request of the chairman of this committee, Frederick L. Hoffman, statistician of the Prudential Insurance Co., summarized and reviewed the available statistics of fatalities in metalliferous mining in the United States. From only six States has it been possible to secure statistics extending over a long series of years. The other States do not report them. The probability is, however, that the actual ratio of fatal accidents in metal mining is larger than the figures reported by Mr. Hoffman, because his figure is based chiefly upon the States which have provided the best mining laws and the best systems of mine inspection. The good of these things is clearly shown by the statistics. Thus, in Colorado and Montana, which among the Western States are conceded to have the best laws, the general tendency of the fatality ratio has been downward. Mr. Hoffman clearly established something that has been strongly suspected, namely, that the loss of life in metal mining in the United States is fully as great as in coal mining. Mr. Hoffman has arrived at the average of 3.09 per 1000 in metal mining, as compared with 3.13 in coal mining.

The chief work of the committee has been in the preparation of a draft for a law. In this work it has invited and received the assistance of several members of the bar, especially Dr. Rossiter W. Raymond, E. E. Ellinwood, and Archibald Douglas. To the valuable co-operation of Mr. Douglas, who devoted a great deal of time to the matter, particular acknowledgment is due. Mr. Douglas prepared the draft for a law finally adopted by the committee. In the preparation of this draft, the committee has had in mind the preparation of a law that will be effective, and not merely a code of rules and regulations of which the enforcement will be largely optional. The committee has aimed to fix responsibility upon operator, superintendent, foreman, and miner respectively, and the failure on their part to comply with the terms of the law is to be punishable by suitable penalties. The conditions of mining in various parts of the United States are widely different. The basic laws of the several States also differ to more or less extent. Consequently, the committee presents its present draft as a preliminary and invites criticism for its assistance in preparing a final report.

In the opinion of the committee, the essential steps toward reducing the loss of life in metalliferous mining are (1) a comprehensive and effective law; and (2) an adequate system of mine inspection. The latter is the keystone of progress. Much can be accomplished by an adequate system of mine inspection, even if a comprehensive law be lacking, but no matter how thorough and effective in theory a law may be, it will fail in its purpose unless provision be made for its sincere, impartial, and positive enforcement by an adequate system of competent mine inspection. To secure such a system of mine inspection, the States must appropriate a good deal more money than any has yet done. Each State must have a mine inspector, and he must be provided with a sufficient number of deputies to enable frequent inspections of all operating mines to be made. One inspection of a mine in a year is not enough. So far as we are aware, the State of Colorado makes the largest appropriation for inspection of metal mines, its appropriation being $25,000 per year. Other important mining States appropriate only $10,000. In the opinion of the committee, such appropriations are utterly inadequate. We operate in this country at a more intense rate than in many foreign countries, and perhaps our death rate per tonnage of ore produced per man would not compare so unfavorably, and because of this more intense operation it may be impossible for us to attain the low rate of some foreign countries. It must be borne in mind that it is not only underground but also overground that accidents are more numerous in this country than in Europe. There is a spirit of recklessness in this whole land that leads people to take risks that the European population avoids. But certainly our mining practice is capable of great improvement with respect to the safety of the miners, and the magni-

*Report of the Committee appointed by the American Mining Congress to draft a law for prevention of mine accidents.

tude of the annual loss justifies a large State expenditure for the purpose of its reduction. It is essential that mine inspection be impartial—absolutely free from all political, personal or selfish interests; and moreover, that it be competent. In its draft for a law, the committee has incorporated, after careful consideration, qualifications for mine inspectors, which, in its opinion, will provide the essential conditions stated above.

Section 1. Defines the terms used in the text of the law, including mine operator, superintendent, mine foreman, inspector and deputy, and excavation or workings.

Sec. 2. Office of Inspector of Mines.—The office of Inspector of Mines for the State of ———— is hereby created. The Governor of the State, by and with the advice and consent of the Senate, shall appoint such Inspector of Mines. The Inspector of Mines shall be at least 30 years of age, a citizen of the United States, a resident of this State for at least one year previous to his appointment, and shall be practically engaged in metalliferous mining, and shall have had at least 10 years' experience in underground mining in the United States of America. The Inspector of Mines (but not the Deputy Inspectors) must have been for at least five years in charge of a mine, in the United States of America, employing 50 or more men underground, to be qualified for such office. He shall receive as full compensation for his services a salary of ———— Dollars ($————) per annum. He shall hold his office for a term of four years (the first term beginning January —, 19—), unless sooner removed by the Governor, or until his successor is appointed and qualified; and in case of vacancy by death, removal, resignation or otherwise, the Governor shall fill such office, for the remainder of any such term of four years, by appointment.

Sec. 3. Deputy Inspector of Mines.—The office of Deputy Inspector is hereby created. The Inspector of Mines is authorized and directed forthwith, upon the entering of the duties of his office, to appoint ———— Deputy Inspectors, who shall each receive a salary payable at the rate of $———— per annum while holding such office. All Deputy Inspectors appointed under the provisions of this section shall be subject at any time to removal by the Inspector. The Inspector shall also appoint hereafter such additional deputies as the Legislature may provide, who shall, when so appointed by the Legislature, be in all ways subject to the provisions of this section. The qualifications of all Deputy Inspectors shall be the same as those required in the case of the Inspector of Mines, as set forth in section 2 of this Act; excepting however, that such Deputy Inspectors shall have been for two years in charge of a mine in the United States of America, employing at least 25 men underground.

Sec. 4. Qualifications and Powers of Inspectors.—No person shall be appointed to the office of Inspector or Deputy Inspector, nor be qualified to hold the office of Inspector or Deputy Inspector, while an employee, director, or officer of any mining, milling or smelting company; or while directly or indirectly connected with any mining company or co-partnership operating in this State; or while engaged in private practice as a consulting engineer. The Inspector and each deputy must devote his entire time to the duties of their respective offices.

Sec. 5. Salary and Expenses.—All reasonable and necessary expenses incurred by the Inspector and by any deputy in the performance of their duties.

Sec. 6. Inspectors Shall be Allowed all Legal Expenses.—The Inspector may employ counsel to represent him, or any deputy, or to assist in the prosecution of actions or proceedings brought under the provisions of this Act.

Sec. 7. Office and Records of Inspector of Mines.—The Inspector of Mines shall be provided with a properly furnished office in which he shall keep a record of all mines examined either by the Inspector or his deputies, showing the dates of such examinations, the condition in which the mines so examined were found, with particular reference to the safety, ventilation and sanitary conditions of each mine so examined, the manner and method of working, all violations of the provisions of this Act found, if any, the action taken thereon, and the result of such action, together with recommendations made in case of each mine examined by the Inspector or any deputy.

Sec. 8. Reports to Inspector of Mines.—It is hereby made the duty of the operator of each and every mine within the State to forward to the Inspector at his office, not later than the 20th day of January, in each year, a detailed report in writing, on a form prescribed by the Inspector, showing the character of the mine, tonnage of ore produced during the previous year, ending December 31, the average number of men therein employed during the year, the number of days the mine was worked, the number of fatal and serious accidents during the year, and such other information relative to the workings, equipment, ventilation, sanitation, means of ingress and egress, shafts, trucking, supports, safety devices, storage of explosives, means taken to protect lives and usual safety of men in relation to any of the requirements of this Act, as the Inspector may, from time to time require.

A failure, neglect or refusal to make such reports or to give such information as are provided for in this section, upon demand made in writing by the Inspector, or by any of his Deputy Inspectors, shall constitute a misdemeanor and every such operator, or persons in charge of such mine, so failing, neglecting or refusing after written demand made shall be deemed guilty of a misdemeanor, and on conviction shall be fined for each offense not less than $50 or more than $200; and each separate failure, neglect or refusal after demand, as aforesaid, shall constitute a separate offense.

Sec. 9. Designation for Service of Notices.—Every operator of any mine within the provisions of this Act, shall, within 60 days after the passage of this Act, file or cause to be filed in the principal office of the Inspector of Mines a designation, duly verified, by such operator, designating a person upon whom all notices, warnings or processes, required to be served under the provisions of this Act, may be served in this State. The person so designated must

have an office, place of employment or place of business within ten miles of the principal place of business of such operator within the State, and such designation shall give the office, place of employment or place of business of such person so designated.

Sec. 10. Secrecy of Records.—The Inspector or any Deputy Inspector, or any person employed by such Inspector or Deputy Inspector, or any person having access to the papers filed in the office of said Inspector, or in the office of any Deputy Inspector, shall not make public or reveal to any person or persons, either orally or in writing, all or any part of the contents of any report, complaint or document filed in the office of the Inspector of Mines of this State, or in the office of any of his Deputy Inspectors, or reveal or make public to any person or persons any knowledge or information in regard to the safety or physical or financial condition of any mine, mining rights, prospect or mining company or concern obtained by any of the aforesaid Inspector, Deputy Inspectors or employees, while in the exercise of their official duties.

Sec. 11. Duties of Inspectors—Inspection—Powers.—It shall be the duty of the Inspector of Mines by himself or by deputy to visit at least once every two months every mine in the State employing 50 or more men underground; and every other mine at least once every year and oftener if in his opinion the safety of the men employed within the mine so requires; and to inspect, inquire and examine into the operation, workings, timbering, safety appliances, machinery, sanitation, ventilation, means of ingress and egress, means taken to protect the lives and insure the safety of the miners, together with the cause of accidents and accidental death therein, and in general, to inspect and ascertain what means are taken to comply with the provisions of this Act.

Sec. 12. Dangerous Mines—Duties of Inspectors.—Whenever the Inspector shall find any mine in an unsafe condition by reason of any violation of any of the rules or provisions of this Act, or in a condition dangerous or detrimental to the life or health of those employed therein, for the reason or by reason of defects in timbering, mining, ventilation or sanitation, it shall be the duty of the Inspector to serve a notice in writing upon the operator of such mine, and such notice shall set forth in detail the nature and extent of the defects which render the mine or part of the mine unsafe, dangerous, or detrimental to the life or health of those employed therein, together with the point or place in the mine, or in the workings of the mine, where such defects exist, and such notice shall require such necessary changes to be made in such mine or part of the mine without delay, and within a specified time in the discretion of the Inspector, to make the same conform to the provisions of this Act.

If it appears from a re-examination of the mine by the Inspector, or a Deputy Inspector, that such necessary changes have not been made within the time specified in such notice, and that the mine or part of the mine is still in a condition dangerous to life or health, it shall be the duty of the Inspector forthwith to institute an action for an injunction in any Court of competent jurisdiction, to restrain the operation and working of said mine, or part of said mine, and the permitting of employees therein for purposes other than to remedy the defects complained of, until the provisions of this law are complied with.

Sec. 13. Refusing Inspection—Penalty.—If the operator of any mine within the State shall fail, impede or refuse to permit such inspection, as is provided in this Act, the Inspector may file affidavit setting forth such refusal before the Judge of the ——— Court in the county in which said mine is situated, and obtain an order directed to such operator, commanding him to permit and furnish all necessary facilities for the entering, examination or inspection of such mine, or to be adjudged to stand in contempt of court and punished accordingly.

Sec. 14. Records of Inspection.—It shall be the duty of the Inspector, or any deputy, after every inspection made of any mine or parts of any mine, as provided in this Act, to enter forthwith in a book to be kept at the mine, and designated as the 'Record of Inspection,' the portions of the mine so inspected, the nature of such inspection, and every illegal defect observed in the condition of the mine, machinery and appliances.

Sec. 15. Complaints to Inspectors.—Whenever the Inspector receives a complaint in writing, signed by three or more persons employed in a mine, setting forth that the mine in which they are working is being operated contrary to law, and is dangerous in any respect to the health or lives of those employed therein, the Inspector must examine such mine as soon as possible.

Sec. 16. Accidents.—Whenever a serious accident occurs in or about any mine, notice thereof shall be given promptly in writing, to the Inspector by the Superintendent or other person having immediate charge of the work at the time of the accident. Upon receiving such notice the Inspector, or a deputy, shall proceed to the scene of the accident and investigate the cause of the accident, and shall file the result of such investigation as a report in the office of the Inspector, within 20 days thereafter.

Sec. 17. Loss of Life.—Whenever loss of life occurs from accident in or about a mine, and when death results from personal injury, the Superintendent or other person having immediate charge of the work at the time of the accident shall give notice to the Inspector, promptly after knowledge of death comes. Whenever possible, the Inspector or a deputy shall be present at every coroner's inquest held over the remains of a person killed in or about a mine.

Sec. 18. Inspector to Forward Papers to Prosecuting Officer in Certain Cases.—Whenever, in the opinion of the Inspector of Mines, a serious fatal accident, in or about any mine shall have been caused by failure on the part of the operator or employee of such mine, or by any other person, to observe the provisions of this Act, it shall be the duty of such Inspector to cause a copy of the report of such accident, and all papers in his hands relating thereto, to be forwarded to the prosecuting officer of the

county, showing in what particular he believes the law to have been violated and if upon the receipt thereof the prosecuting officer of the said county deems the facts to make a prima facie cause of action against any party, he shall present such evidence to the Grand Jury and take such further steps for the criminal prosecution of such operators, employees, or other person, as may seem advisable.

Sec. 19. Statistical Reports of Mine Inspector.—It shall be the duty of the Inspector of Mines within three months after January 1st in each year, to make a report directed to the Governor and Legislature giving a statistical summary and report of the work of the Inspector and Deputy Inspectors of Mines during the previous year ending December 31st. Such report shall contain a statement showing the number of men employed in each mine above ground and underground, the number and nature of fatal and serious accidents occurring in each mine, the number of inspections made, and any other information deemed important.

Sec. 20. Removal of Inspectors and Deputy Inspectors.—Upon a petition signed by 100 miners, or 10 operators, or by three operators each employing 100 men underground, setting forth that the Inspector neglects his duties as prescribed in this Act, or that he is incompetent, and unqualified for the office of Inspector, or Deputy, as the case may be, or guilty of malfeasance in office, or guilty of any unlawful act tending to the injury of miners or the operators of mines, it shall be the duty of the Court to issue a citation to the Inspector, or Deputy Inspector, to appear on a day fixed, before said Court, and the Court shall investigate the allegations of the petitioners. If the Court shall find that said Inspector, or Deputy Inspector, is neglectful of his duties, or that he is not qualified under the provisions of this Act for such office, the Court shall certify the facts so found to the Governor; in the case of such finding against an Inspector, and to the Inspector of Mines, in the case of such finding against a Deputy Inspector, and the Governor or Inspector, as the case may be, shall declare the office of Inspector or such Deputy Inspector vacant, and steps shall be taken to appoint a properly qualified person to fill such vacant office of Inspector or Deputy Inspector.

Sec. 21. Care of Injured.—It shall be the duty of operators, Superintendents or any one in charge of any mine where ten or more men are employed, to keep at the mouth of the drift, shaft or slope, or at such other place as may be designated by the Inspector, a stretcher and a woolen and waterproof blanket, for use in carrying any person who may be injured at the mine. Where more than 200 persons are employed, two stretchers and two woolen and waterproof blankets shall be kept. And at all mines a supply of antiseptic gauze, carbolated vaseline, sponges, soap, carbolic acid, tables of bichloride of mercury, linseed oil, bandages, suitable towels and a wash basin shall be kept readily accessible for the treatment of any one injured. Provided, that in all mines where 500 or more men are employed, a First Aid Corps must be organized.

Sec. 22. Mine Maps.—The operator of every mine, employing ten or more men underground, shall maintain an accurate map of the workings of such mine. At least once in every six months, the operator or Superintendent shall cause to be shown on the map of said mine, all the excavations made therein during the time elapsed since such excavations were last shown on said map.

Sec. 23. Failure to Make Map—Remedy.—Whenever any operator or Superintendent of any mine employing more than ten men underground, shall neglect or refuse to make such map of the workings, for a period of three months after the receipt of written notice so to do by the Inspector, or fails to add to such map all excavations made, then the Inspector is authorized to cause a correct survey and map of such mine to be made at the expense of the operator thereof, the cost of which shall be recoverable at law from said operator as other debts are recoverable by law.

Sec. 24. Storage of Inflammable Material.—It shall be the duty of the operator or Superintendent of each mine to store, or cause to be stored, oils and other dangerously inflammable materials in a covered building, kept solely for such storage, which building shall be at least 100 ft. from any other building and at least 300 ft. from any powder magazine.

Sec. 25. Storage of Explosives.—No blasting powder or any high explosive shall be stored in any mine. Provided, that nothing in this section shall be construed to prevent the operator of any mine from keeping sufficient blasting powder or other high explosive within such mine to meet the estimated requirements of such mine during the succeeding 24 hours; and provided, that such temporary supply shall not be kept at any place within such mine, where its accidental discharge would cut off the escape of miners working therein.

Sec. 26. Marking of Explosives.—It shall be unlawful for the operator or Superintendent of any mine to permit the use within such mine of any explosive containing nitro-glycerine unless there shall be plainly printed in English, on every package containing such explosive the name of the manufacturer of such explosive, together with the date of its manufacture.

Sec. 27. Superintendent to be Appointed.—The operator of every mine shall appoint a man who shall be in charge of the mine and the work done therein, who shall be designated as the 'Superintendent.' The Superintendent shall inspect, or cause an inspection to be made by some competent person of all mining appliances, boilers, engines, magazines, shafts, shaft houses, underground workings, roofs, pillars, timbers, explosives, bell ropes, speaking tubes, telephones, tracks, ladders, dry closets and all parts and appliances of said mine in actual use, and any such person or persons appointed by the Superintendent shall report any defects therein. It shall be the duty of the Superintendent upon ascertaining any such defects to take immediate steps to remedy the same so as to make the same comply with the provisions of this Act.

Sec. 28. Mine Foreman—Appointment.—The operator or Superintendent of every mine shall appoint a man who shall be personally in charge of the carrying out of the underground workings of the mine, and who shall personally direct the work of the men employed underground therein, who shall be designated as the 'Mine Foreman.' No person shall be appointed to the position of Mine Foreman who shall not be at least 21 years of age, and shall not have had at least two years of practical experience as an underground miner in metalliferous mines, and who shall not be able readily to read and write the English language.

Sec. 29. Duties of Mine Foreman.—The Mine Foreman shall attend personally to his duties in the mine, and shall see that the regulations for securing the safety of all men employed in such mine are carried out.

Sec. 30. Blasting.—Gang bosses shall be in immediate charge, and responsible for blasting within the mine. It shall be their duty to see that no iron or steel tools shall be used for tamping, and all miners are forbidden to use iron or steel tools for such purposes. It shall be the duty of the Mine Foreman to fix the time of all blasting and firing. Gang bosses and miners about to fire shots shall cause warnings to be given in every direction, and all entrances to the place or places where charges are to be fired shall be guarded while such firing is going on. In the event of shots fired by electricity, it shall be unlawful for any person knowingly to enter the vicinity of the mine where such shots are fired until the cable of the firing battery has been disconnected: it shall be the duty of the gang boss or miner in charge of the shot-firing to see that all such cables are disconnected immediately after such firing, and to examine, or direct the examination of such place where shots are fired, before any men are permitted to work therein. It shall be unlawful for any miner to extract or attempt to extract explosives from a hole which has once been charged, but in every such case a fresh charge shall be inserted above the missed explosive, and the same shall then be detonated. It shall be unlawful for any miner to deepen holes, or any part of holes, left standing or abandoned, and theretofore charged with explosives.

Sec. 31. Hoisting Engineer.—It shall be the duty of every Superintendent of every mine having a hoisting engine to appoint and designate one or more men, who shall be able to speak and read the English language readily, to be known as Hoisting Engineers. At all shafts where men are hoisted or lowered such hoisting engineers shall be not less than 21 years of age, and at shafts where men are not so hoisted or lowered they shall be not less than 18 years of age.

Sec. 32. Duties of Hoisting Engineer.—The following rules shall be observed by every Hoisting Engineer employed within this State: (1) It shall be the duty of every Hoisting Engineer to keep a careful watch over his engine and over all machinery under his charge. (2) He shall at all times be in immediate charge of his engine, and shall not at any time delegate any of his duties to any other person. (3) He shall familiarize himself with and use all signal codes for hoisting and lowering as directed to be used in this Act. (4) He shall not run his engine unless the same is properly provided with adequate brakes, indicators and distance marks on hoisting ropes or cables, as provided in this Act. (5) It shall be the duty of the Hoisting Engineer to exclude every person from his engine room, excepting any person or persons whose duties require their presence therein. (6) He shall hold no conversation with any one while his engine is in motion, or while attending to signals. (7) He must run his engine with caution whenever men are on the hoisting cage. (8) He shall not hoist men out of, or lower men into, any mine or shaft at a speed greater than 800 ft. per minute. (9) He shall inspect all hoisting machinery and safety appliances connected therewith, and all ropes and hoisting apparatus, as directed by the Superintendent, and shall report to him any defects found. (10) After any stoppage of hoisting for repairs, or for any other purpose exceeding one hour, he shall run a cage or other conveyance, unloaded, up and down the working portion of the shaft at least once, and shall not permit the cage or other conveyance to be used until the hoisting machinery and shaft are found to be in safe condition. (11) He shall do not hoisting in any compartment of a shaft while repairs are being made in the said compartment, excepting such hoisting as may be necessary to make such repairs. (12) He shall familiarize himself with and carry out the requirements of Rules 7, 8, 9, 10, 11, 12, 19 and 20 of Sec. 37 of this Act. (13) Any Hoisting Engineer or any person having in charge the hoisting machinery connected with the mine who shall wilfully violate any of the provisions of this section, or any of the rules contained therein, or who shall wilfully violate any of the provisions of Rules 7, 8, 9, 10, 11, 12, 19 and 20 of Sec. 37 of this Act, shall, upon conviction, be deemed guilty of a violation of this Act and liable to punishment accordingly. (14) The Superintendent shall post a copy of this section and the last preceding section in a conspicuous place on the door of the engine house.

Sec. 33. Hoisting Ropes.—It shall be unlawful to use in any mine any rope or cable for hoisting or lowering either men or material, when such hoisting or lowering is done by any means other than human or animal power, unless such rope or cable shall be composed of iron or steel wires, with a factor of safety determined as hereinafter set forth. The factor of safety of all such ropes or cables shall in no case be less than five, and shall be calculated by dividing the breaking strength of the rope as given in the manufacturers' published tables, by the sum of the maximum load to be hoisted, plus the total weight of the rope in the shaft when fully let out, plus 10 per cent of such values, to take account of shock at starting and stopping. All ropes must be inspected once in every 24 hours by some competent person designated for that purpose by the Superintendent, and it shall be the duty of the Superintendent to cause an examination to be made once in every succeeding three months of a section of

such rope or cable, then in use for hoisting and lowering men and materials in such mine.

Sec. 34. Cages for Hoisting Men.—It shall be unlawful for the operator or Superintendent of any mine to permit the hoisting or lowering of men through a vertical shaft deeper than 300 feet, unless an iron-bonneted safety cage be used for hoisting and lowering of such men, but this provision shall not apply to shafts in process of sinking. Every cage must have overhead bars of such arrangement as to give every man on the cage an easy and secure hand-hold. Every cage or skip used for hoisting men must be provided with a safety catch of sufficient strength to hold the cage or skip with its maximum load at any point in the shaft in the event that the hoisting cable should break.

Sec. 35. Boilers and Connections, Machinery, etc., Inspection.—All boilers used for generating steam in and about mines shall be kept in good order, and the owner, operator or Superintendent shall have them examined and inspected by a qualified person, not an employee of said operator, as often as once in six months, and oftener if the Inspector or his deputy shall deem it necessary. All machinery used in or about the mine, such as engines, wheels, screens, shafting and belting shall be protected by covering or railing so as to prevent persons from inadvertently walking against or falling upon the same. The sides of stairs, trestles and dangerous plank walks in and around the mines shall be provided with hand and guard railing to prevent persons from falling over the sides.

Sec. 36. Prohibited Employment of Women and Children in Mines.—No woman or girl, and no boy under the age of 16 years, shall be employed or permitted to work within any mine within this State.

Sec. 37. Rules.—These rules deal with the following matters each being treated in detail: Additional duties of mine foreman and assistant mine foreman; candles; fire-fighting helmets; cages; hoisting while shaft sinking; deepening shaft-protection; whims; hooks; cross-heads; signals; punishment for interference with signals; signal codes; timbering; fencing disused shafts; abandoned shafts; penalty for destroying fencings and coverings; lighting; manholes; machinery and protection; protection against water; ladders and ladderways; enforcement of rules; passageway around shaft; sumps; stopes; winzes or raises; shaft stations; top of shaft; hoisting ropes; explosives; fuses; general rules.

When retorting, to prevent gold adhering to the sides of the retort, or to the cups placed in the large cylindrical retorts, the inside of the small retort or of the individual cups should first be well covered with a film of chalk or coated with a mixture of fine fire clay and graphite ground to a thin paste. Paint the inside of the retort with this and allow it to dry thoroughly. Clean the amalgam to remove all iron, and other foreign substances, and avoid heating retort above a bright red. If these instructions are carefully followed, there is little likelihood of the gold adhering to the sides of the retort or to the cups, if they are used.

SAFE AND CONVENIENT THAWER

When nitro-powder is exposed to a temperature approaching 45°F., it practically freezes and its usefulness as a blasting agent is largely impaired, or wholly destroyed, though it is still extremely dangerous to handle. Miners, and more particularly prospectors, are much given to the innocent but extremely dangerous practice of placing sticks of dynamite against an inclined board, set before an open fire. This means of thawing powder is direct and gives the minimum of trouble, but it is also a means which often has deprived men of hands, eyes, or fingers, or otherwise mutilated them, while not a few have lost their lives. The safest way to thaw dynamite is in a can that is immersed in gently heated water. The accompanying sketch illustrates a simple, economical, and perfectly safe method of thawing frozen dynamite. It consists simply of an empty oil, or liquor barrel, fitted with return water-heating pipes, as shown, consisting of three pieces of 1¼-in. pipe and two elbows. The pipes are firmly screwed or driven into the side of the barrel, one near the bottom, the other near the top, but both below the water-level. The pipes should project 4 or 5 ft. from the barrel. Inside the barrel and about half way between top and bottom, a rack or platform should be arranged, upon which a 5-gal. oil-can may rest. This can be secured in place so that it will not float when the water is turned into the barrel. This may be done by means of cleats or weighting the can with iron or rocks. Fill the barrel with water to within two inches of the top of the can, and in the can place the powder to be thawed. Then build a fire under the pipe, as indicated in the sketch. The heated water rising in the vertical pipe enters the barrel and is replaced by cold water from the bottom of the barrel. In an hour, or so, all the water in the barrel will be scalding hot if the fire be kept up, but such high heat is neither necessary nor desirable. The powder thaws gradually and is safe at all times during the operation. The barrel should be provided with a substantial cover fitted with a handle, by means of which it may be readily removed. A separate cover for the can within the barrel would be an improvement, as it would prevent any condensation from the hot water accumulating in the can. It would also improve the outfit if the can were provided with a false bottom which could be easily removed. One thing must not be neglected in this or any other type of powder thawer—it must be kept absolutely clean at all times. If powder is thawed in it for some time and the can is not cleaned, small quantities of nitro-glycerine will accumulate in it, and some day an explosion will result.

The above table shows the number of pounds and ounces of KCy necessary in any given number of tons of solution from one to thirty at strengths varying from 0.01 to 0.5%. This table has proved convenient for standardizing sump solutions. The top row of figures indicates the tons of solution to be made up to a standard strength and the decimals in the left-hand column are the strengths of solution. The number of pounds and ounces necessary to be added to the solution will always be found in the angle of the lines of these figures. For example, to find the number of pounds of cyanide necessary to add to 13 tons of solution to raise its strength 0.17%, follow down the column headed by 13 to the line on which the decimal 0.17 is found. The figures 44-3 there found, give the answer, 44 pounds and 3 ounces.

It is convenient to have indicators on the solution tanks marked in tons in preference to feet, since solutions are recorded in tons when calculations are made for standardizing or for running a given quantity on a charge of ore or for making pulp.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Cyanidation of Concentrate

The Editor:

Sis—The article in the August 27 issue 'Cyanidation of Concentrate,' by F. C. Brown, was particularly interesting and instructive, coming from an engineer whose reputation is world-wide, and who has done so much to bring the cyanide process to its present state, nearing perfection, both chemically and mechanically. Mr. Brown's article deals with finer grinding of the concentrate. I really wanted information about the process and results obtained when the concentrate was not reground. I will admit it is a crude way to treat it, but I plead 'not guilty' to the arrangements. A great difference of opinion existed at a certain plant, as to the best way to feed the solution, also the quantity. I shall explain the plant to be more clearly understood.

The ore was crushed through 20-mesh so called, amalgamation inside and on 12-ft. outside plates. Concentration was effected on a table and a 6-ft. vanner. There was no classification. The tailing went to waste, the concentrate to the tanks, by sluicing. The ordinary different length arm distributer was used, but it did not revolve, as the wheels of the carriage had been removed to allow of more grade from the concentrators to the tanks. This was revolved at times to allow a more even distribution in the tanks. A tank was filled in about 10 or 12 days. Lime was fed to neutralize acidity, but the amount I cannot give, on account of conflicting opinions; the alkalinity was kept at two and one-half, and the standard solution was 8 lb. per ton. The latter was used continuously and re-standardized. An argument arose as to the way of feeding the solution. The 'psendo' in charge claimed that a better extraction would be gained by feeding a certain amount. I must state that solution was fed in the tanks for 12 hours and the other 12 was reserved to drain same. No account was kept of the amount of solution pumped, or used. The millmen pumped the solution on night shift when the storage tank was empty. The other opinion was that a better extraction would be obtained by using all the solution that could be run on, for the reason that the chief aim was the greatest possible contact between the gold content of the concentrate and the percolating solution. Will any engineer who reads this kindly give his opinion?

Sands, of course, would present a different proposition, but in the treatment of this concentrate I personally am inclined to agree with the latter statement given by the man running the plant, and not with the 'psendo' in charge, for this and many other reasons. The young man in charge was decidedly better qualified to express an opinion, even if he should be wrong in this case.

Again, if too much lime were fed on the tanks, would it tend to form a slimy, or colloidal, matter on the zinc shavings in the boxes? It was found that this only occurred when the gold tanks became empty, and the colloidal matter in the bottom was allowed to run into the zinc boxes. The gold tanks were absurdly small, and often the flow into the zinc boxes had to be cut down to prevent this. In both cases the amount of precipitate obtained was cut down. Is this matter in the bottom of the tanks caused by adsorption? And would the solution so often used carry impurities which would cause a loss in the extraction by imperfect contact in the tanks and precipitation in the zinc boxes?

INGENIERO KCN.

San Francisco, September 30.

The Editor:

Sir—From all that I can learn concerning the treatment of concentrate by cyanidation, the greatest success attained has been after fine grinding, taking care always to expose the concentrate as little as possible to oxidizing influences. The experiments of Dr. Schidell at the Utica mine at Angels, California, those of W. G. Scott at the Black Oak mine, Soulsbyville, California, and of Mr. Diggles and others at the Mclones mine, Robinson, California, all resulted in securing the highest extraction from finely-ground sulphides. In some instances as high as 96% extraction was reported as obtained from concentrate from canvas tables whereas the highest extraction on vanner concentrate seldom exceeded 72% of the gold and even less of the silver present. Experiments reported by others indicate that whatever may be obtained from ordinary concentrate, such as is generally recovered from concentrating machines, a much higher extraction is possible on the same material when it is finely ground. On low-grade sulphide it may not pay to regrind prior to cyanidation even if a higher extraction is obtainable by that means, consequently it resolves itself into a commercial problem, as well as a metallurgical one, for there are few metallurgists who take pride in carrying their operations to a point where the cost of recovery of metals exceeds their commercial value. Often a process is worked out successfully, when viewed from the chemical or metallurgical standpoint, but which is too expensive to admit of its application along commercial lines. The metallurgist then continues his experiments with a view to reducing the cost of the operation, and not infrequently he, or, as likely, some one else, succeeds in this and the 'impossible' process becomes a recognized commercial possibility and gladly accepted as such by all who have use for it.

CYANICIDE.

Seattle, September 22.

Esperanto

The Editor:

Sir—Doubtless you have long since formed your opinion as to the merits of Esperanto, the international language. I hope that it is favorable; but as there has been much criticism of Esperanto, especially on occasion of the recent international convention in Washington, I want to offer an opportunity

for every thinker to judge for himself. I have had prepared 100,000 brief grammars of the language in pamphlet form, and will send one free to any person who is sufficiently interested to ask for it, enclosing stamp for reply. I think it really due to this great movement for an international auxiliary language, which now embraces fifty nations in its scope, that you publish this letter, so that your readers may have the opportunity of judging for themselves.

ARTHUR BAKER.

700 E. Fortieth Street, Chicago, Ill.

[Doubtless there are many who will wish to avail themselves of this offer of Mr. Baker, that they may have an opportunity to investigate the mysteries of Esperanto.—EDITOR.]

The Make-Shift in Mining

The Editor:

Sir—Mining is a business which in most cases requires large capital for equipment and development, and often a goodly sum for operation as well, and those whose lot has been cast among the more fortunate enterprises, where capital was abundantly supplied; where every modern device was sought regardless of its cost; and where the prevailing idea was that thoroughness in up-to-date equipment meant economy of operation, would be surprised to know how much can be accomplished with the simple and inexpensive, though ingenious, mechanical contrivances, introduced by mine owners of small capital—often practically none at all, and by lessees whose bank account was all to be created. When I first went to Leadville and into Cripple Creek district the mines which I had left and with which I had grown up were large affairs. Ponderous hoisting machinery, great mills, and large-scale operations were familiar, and I was surprised to see some of the mines of the two Colorado districts mentioned which had become famous for output, and had earned world-wide reputations, equipped with small hoisting plants; two-post head-frames from which dangled trip-ropes, and many of them without mills of any description. In some instances a tripod straddled a shaft answering the purpose of a head-frame, and yet it had served its purpose in hoisting with a 'dinky' engine upward of a million dollars worth of ore. In Joplin district, of Missouri, may be seen surface equipments which would, and do, bring a broad smile to the face of a Western States' mining man, and yet these cheap, home-made affairs answer every purpose and not a few of them could be copied with advantage by some of our Western engineers, who like to plan and construct large works—too often before they have a mine. The tripod and the simple two-post head-frame, with their trip-rope attachments, have their place in the economy of mining as well as the tall, carefully designed, steel structure with automatically-dumping skips. Many a lessee has 'got his start' by working faithfully 10 hours or more a day, operating a hand-jig in making a rude classification of his ore—and not so rude either, for the hand-jig, when properly constructed and operated, is by no means a poor concentrator, but it is, like its fellow pioneer, the arrastre, a machine of woefully low efficiency, but again, each answers a certain useful purpose, and is the poor miner's make-shift. Much can be accomplished by means of these homely mechanical contrivances, and they should not be despised, for it is safe to say that the proportion of failures where the windlass, the dinky engine, the arrastre, and the hand-jig have been the main features of equipment, has been below that of those ventures characterized by magnificence of surface equipment and abundance of hot-air enterprise, at any rate the results of the failures of the former type have been less far-reaching in their disastrous consequences, involving but few and generally survived by the principals. Not that the principals of the latter kind do not survive—unfortunately they too frequently do, to repeat over and over again their peculiar hobby, that of extravagant equipment regardless of the actual demands of their enterprise.

San Francisco, September 24.

Indications of a Mine

The Editor:

Sir—I have frequently heard men claim that they could tell from surface indications whether a mine was good or not, some of these men even going so far as to pretend to be able to tell before the property was developed whether it would prove to be a valuable mine or not, when opened up. From my personal experience, which has been somewhat limited, I will admit, I have found it difficult to determine the value of a mine, even after it was developed, to say nothing of appraising it before it was opened. If there is anything in this forecasting the value of a mine before development I should like to know something more about it, and how it is done, if it is not a secret, and any one can learn how to do it. I do not deny that I am very doubtful as to the ability of any one to do this, still, there may be some who can. If so, I should like to know how.

MISSOURI.

Los Angeles, September 23.

[There are often certain physical and geological indications at the surface by means of which some geologists and engineers form an opinion as to the probable outcome of the development of a new property, but there are few who will go so far as to state even approximately the value of any undeveloped mine. Those geologists and engineers who have made these superficial indications a study may state that in their opinion a new mine is likely to become valuable or that there are indications which point to unsatisfactory results upon development, and it is surprising with what a degree of accuracy such predictions may be made under certain circumstances. In some instances it would, no doubt, be extremely difficult to make such forecast with any degree of assurance but in certain other cases it can be attempted with wonderful success. This is a large subject, and one upon which we will have more to say in a subsequent issue. The physical conditions referred to are simple and easily understood and the laws, if they may be dignified by so radical a term, are applicable to mineral veins in many regions.—EDITOR.]

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Mercury traps are advisable in any gold mill, as they will generally save particles of gold, and amalgam as well as globules of quicksilver that escape from the plates.

Dampers in smoke-stacks leading from boilers should never be closed completely when there is fire on the grates as gas may accumulate and finally explode with disastrous results.

Gold is obtained as a by-product in dredging for tin in some of the streams of Tasmania. In New South Wales gravel containing less than two pounds cassiterite per ton is profitably dredged.

Vanadium ores are produced chiefly in western Colorado, from roscoelite and carnatite. The roscoelite is found in a thin layer of greenish sandstone near Newmire, and the carnatite near Cedar and in the La Sal mountains near Paradox. Mining operations are carried on in a small way near Newmire, where the ore, carrying 1 to 3% vanadium, is treated in a mill, the product being iron vanadate.

The gold veins of Porcupine district, Ontario, are described as occurring in the schists and quartzites of the Huronian and Keewatin, and vary from a few inches to 80 ft. or more. The veins are of white quartz, some of which is rich in coarse gold. Sulphides are found in all the veins, sometimes abundantly. The ore is stated to be free milling. The Porcupine camp is 100 miles north of Cobalt and 400 miles north of Toronto. There are over 2000 people now in the district.

Capacity of stamp-mills is influenced by many considerations, among them the width and shape of the mortar, weight of stamps, height and number of drops, height of discharge, size and kind of screen, and superficial area of screen, amount of water fed, and as important as anything else, the character of the ore. A granular ore will generally crush more rapidly than a flaky ore, such as flint. This latter will discharge more rapidly through a slotted sheet-steel screen than through one of woven cloth.

Lake Lahontan is the name of an ancient Quaternary body of water in western Nevada. All that now remains of this once large body of water, covering at one time 8422 square miles, and draining an area of 40,000 square miles, is a lake bed in which water covers but one twenty-fifth to one thirtieth of its original surface. Like all other lakes, Lahontan continued as a body of fresh water so long as the annual rainfall exceeded the annual evaporation, but when the evaporation exceeds the rainfall the area of the lake begins to diminish, and if these conditions continue the lake gradually becomes smaller, eventually drying up altogether. The Western Pacific railroad runs along the bed of this famous dry lake for more than 130 miles. The terraces which mark the irregular recession of the water, can be plainly seen skirting the lake shores for many miles.

In the arrastre the drags should be drilled to a depth of several inches near the edge on the upper side, and iron eye-bolts inserted (wooden plugs will do), to which chains may be attached. The drags should be so disposed from the horizontal rotating arms that they will pass over the entire surface of the basin with each revolution of the central post. The drags should be of the hardest and toughest stone available, and should weigh 200 to 300 lb. each. Massive greenstone and fine-grained granite make good drags. Each drag should be suspended so that one edge is lifted above the basin an inch or two, the opposite edge resting on its floor. This permits the broken ore to pass beneath the drag as it sweeps around the basin. If the drag lies flat it will push the ore along in front of it and its grinding capacity will be greatly diminished. In order to secure capacity the rock should be crushed to small size before going to the arrastre. This may be rapidly done by breaking the ore to size of hazel nuts or smaller, in a large hand mortar over which is suspended a heavy pestle from a spring pole. The operator will find plenty of time to do this while a charge is being ground in the arrastre. A speed of 30 revolutions a minute is not too fast, and even this is rarely reached where animal power is employed. Arrastres are sometimes driven by water-power, and occasionally by gas engines.

In pan amalgamation of gold and silver ores, the method of feeding and discharging the pans continuously is known as the Boss process, after the inventor, M. P. Boss. No pan amalgamation is accomplished without the addition of copper sulphate and sodium chloride (salt), to the charge as well as mercury. The chloride of silver, whether a natural constituent of the ore, or produced from the sulphides by chloridizing roasting, becomes metallic in the presence of the chemicals in the pan with the iron particles, derived from the crushing machinery and from the pan muller. The quicksilver then amalgamates the metallic silver and the gold present. There is no tendency on the part of the chloride of silver to flour the mercury, and if this is taking place in the pan it is due to some other cause, possibly some deleterious mineral in the ore, such as antimony, arsenic, or manganese di-oxide. The grinding should be done before the mercury is fed to the charge. This requires from four to eight hours. The mullers are then raised and the quicksilver for amalgamation added. It is important that the charge in the pan be neither too thick nor too thin. If the former the mercury will become finely divided and may flour, causing loss, as it seldom is all re-collected in the settler. If too thin the mercury will not rise from the bottom of the pan and thoroughly mix with the ore, which escapes in the tailing carrying away a portion of the precious metal that might have been saved. Also, the pan-mullers must be rotated at proper speed, with a view to proper mixing of pulp and mercury. Zinc amalgam is one of the best correctives for floured quicksilver.

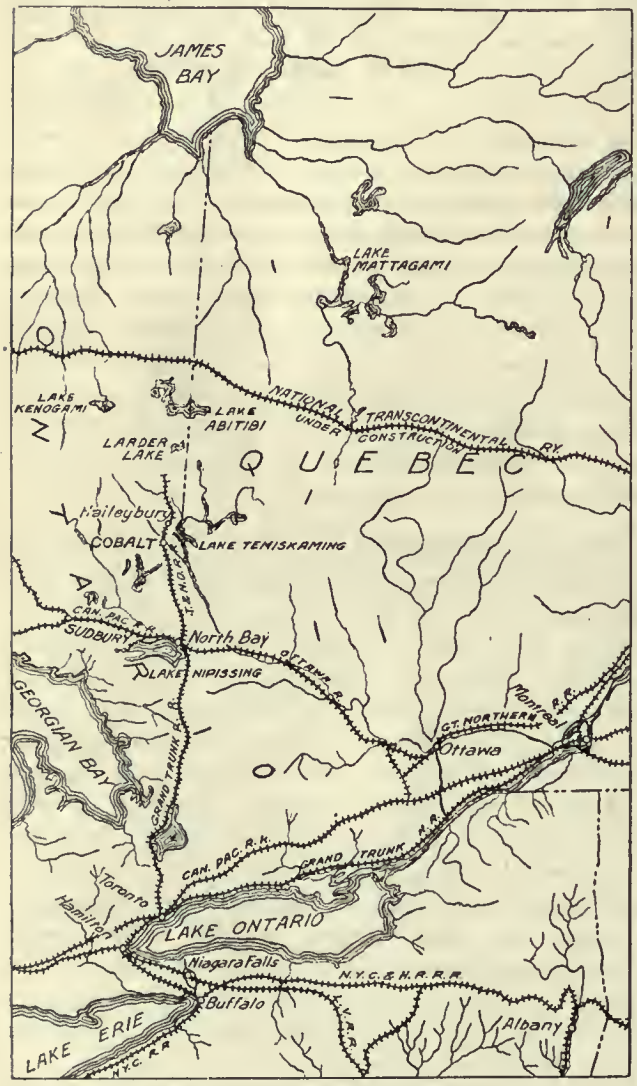
TORONTO, CANADA

Increased Market Activity. — New Orebodies. — Government Subsidy.

The past two or three weeks has witnessed a marked revival of public interest in the Cobalt mining issues, confined almost altogether to the lower-priced stocks, which have advanced considerably all along the line. Buying orders have lately been coming in freely from New York, as well as from Haileybury, Cobalt, and other points in the mining region, and the profit-takers are now taking advantage of the situation, causing a swift recession. A noteworthy feature has been the rehabilitation of the Green-Meehan, the stock of which had for some time been on the bargain counter at from one to two cents. The leasing of



Map Showing Portion of Quebec.

the property for five years to a syndicate headed by E. C. Kingswell, under whose management $30,000 will be spent in development, created a heavy demand for the stock, large quantities of which changed hands at from 4 to 6c. Good news from the camp has also given an uplift to the Beaver, Temiskaming, and Rochester issues, and the brokers begin to anticipate an active fall season. The August statement of the Temiskaming shows a total production from mine and mill of 251,968 oz. silver of the net value of $125,984, the cost of production being $22,014, leaving a profit of $103,969. New veins have been struck at the Beaver; recently in driving from the winze on the 300-ft. level a vein carrying 5000 oz. ore was cut, and subsequently a 10-in. vein was found in new territory at the end of a cross-cut on the 200-ft. level, and another 8 in. wide., on the 250-ft. level in a cross-cut east from the main shaft. The latter is 30 ft. from the Temiskaming line, on the other side of which the ore assays between 3000 and 4000 oz. per ton. These finds encourage the hope that development at depth will bring good returns. A rich surface vein has been found on property adjoining the Rochester, about 100 ft. from the old Rochester shaft, in which the vein was lost at a depth of 50 ft. two years ago. It is supposed to be the missing vein and driving will be undertaken to pick it up. The Nova Scotia is working in very rich ore, stated to assay 10,000 oz. per ton, on the fifth level, but its ownership is doubtful, as the strip which contains the vein is the subject of litigation between the Nova Scotia and Peterson Lake companies.

A 12-in. vein has been found in the Ophir shaft at a depth of 286 ft., containing niccolite, argentite, and some ruby silver. It is uncertain whether it is a new vein or one which disappeared at 250 ft., at which depth it showed a width of 5 in. The Black Mines Consolidated has exhausted its funds and the shareholders have authorized the pledging of all assets to secure a loan of $25,000 to carry on operations. A particularly audacious robbery was committed at the Nova Scotia mine, Cobalt, on the night of September 5, when a gang of burglars bored through the walls of the concrete vault over a foot in thickness, and abstracted 27 bars of bullion valued at $17,500. They were evidently professionals and it is thought must have been familiar with the premises. The Mikado gold mine in the Lake of the Woods district bids fair shortly to rank among the producers. Work was recently resumed and stoping and development are going forward actively on the upper levels. The mine has been unwatered down to the 400-ft. level. It is estimated that there is enough ore of milling grade in sight to keep the 20-stamp mill going for two years. A gold bar, valued at $1200, has been obtained from sweepings collected while the mill was being repaired. Twenty-six men are employed.

William Templeman, Canadian Minister of Mines, made an important announcement at Nelson, B. C., in the course of the tour through the west by Sir Wilfrid Laurier and his party. He stated that the Department had decided to grant a further subsidy for lead ore and to undertake experiments with a process for recovering metal from the low-grade now prevalent in that district. Two experts had been engaged to conduct the experiments which would be made at the Nelson smelter. A party, including John W. Gates of New York, D. D. Mann of Toronto, J. J. Mitchell of Chicago, Joseph Sellwood of Duluth, and other capitalists, last week inspected the Moose Mountain Iron mines, north of Sudbury. The present output is 400 tons of concentrated ore per day, which within a year will be increased to 1000 tons. The ore is marketed in Cleveland.

LONDON

Dolcoath.—Carn Brea & Tincroft.

In my last letter I referred to the Dolcoath mine and its most recent developments. At the meeting of shareholders held this week, R. Arthur Thomas, the manager, gave some information in addition to that contained in his half-yearly report. The most important was that the current half-year's output would probably be less than the recent average, owing to the dismantling of some of the old Cornish stamps which are to be replaced by Holman air-cushion stamps. He described shortly the electrical plant now being installed at the new shaft and mentioned that the pumps will only handle the water from the lowest levels, the pumps in Harriett's shaft being left to deal with the upper flows. The general impression given at the meeting was that, though the dividend has been passed for the first half of the present year and the output is being temporarily reduced, the situation will be greatly improved by next spring. Not only will the capacity of the dressing plant be increased, but the amount of ore raised will be greater and the cost of mining diminished.

The present position of Carn Brea & Tincroft, an old combination of mines between Camborne and Redruth, is once more critical. Details of the position were given recently, but briefly it may be stated that the company has

arrived at a stage of its history when modern methods must be applied. It is usually said that the curse of Cornwall is the unsympathetic greediness of the owners of the mineral rights, and when we remember that the Tehidy Estate exacted a 'fine' or premium of £30,000 on the renewal of the Dolcoath lease some years ago, it is no wonder that bitter feelings are extant in Cornwall. The Carn Brea & Tincroft company has two lords; the Carn Brea belongs to the Tehidy Estate and the Tincroft to Lord Clifden. The latter is more liberal to the mines than Mr. Basset of Tehidy. Probably he can afford to be so, seeing that he draws immense royalties from the more prosperous industry of china-clay in the St. Austell district. He has foregone his royalties at Carn Brea & Tincroft during the last twelve years to the extent of £15,000, and has in addition invested £12,000 cash in the purchase of shares. At the recent meeting of shareholders his agent, John Gilbert, who is his representative on the board of directors, spoke pretty plainly to those who wanted further favors from the ground landlord. His two points were well made and hit his fellow directors hard. In the first place he reminded the shareholders that he had for years strenuously advocated the adoption of magnetic separation, for the reason that not only was a valuable mineral wolfram, being lost as a source of income, but that its presence in the tin concentrate caused the price obtained to be £5 to £10 less per ton than the better qualities sold at the 'ticketings.' To prove his belief he announced that Lord Clifden would personally stand the expense of putting up a magnetic plant. Mr. Gilbert's other point was that the buying of plant and stores was conducted in an uneconomical way. This is a delicate question, and unfortunately it is one that might be discussed at other mines in Cornwall. The manager has no free hand to buy materials in the cheapest market. In other words, he is tied, and purchases are made to suit the influential dealers who have a 'stake' in the mine. Some interesting remarks were also made at the shareholders' meeting, by James Wickett, the stockbroker of Redruth. He spoke plainly and said that the reason he preferred tin properties in the East Indies was that lord's dues and vested interests were not the controlling factors of the situation there as they are in Cornwall. This attitude of Mr. Wickett explains his policy of recommending tin investments in the Malay rather than in Cornwall.

ST. PETERSBURG, RUSSIA

Central Asian Gold.—Syr Darinsk Province.—Samarkand Province.—Ferghana.—Semirctchensk.

Although some mention has been made of the existence of lode gold in Turkestan, the same has not been discovered, though many efforts have been made to find it. The mining engineer Kulivin, who went over the ground especially with the object of finding veins of lode gold, as did also the investigator of Turkestan, Seviertzef, declared that there must be lode gold on the upper reaches of the rivers Tchirtchik and Talassa. This of course is common to great tracts of land in Asia. Investigators are firmly persuaded that lode gold does exist; but hitherto they have had to be content, at all events the practical ones, with the working of alluvium. It is well known that gold sands have been worked on the tributaries of the rivers Tchetkal, Talassa, Kegen, and Zaravschan. These sands are usually to be found on the banks of the rivers in contiguity to considerable expanses of granite, and on the tributaries where granite has not been exposed the gold sands have not been found.

Gold has been found in the Syr Darinsk province by the natives in the river, alluvium resulting from the decomposition of granite, porphyry, and limestone. Work in connection with the exploitation of these deposits has chiefly been conducted along the bed of the Tchirtchik where the gravel yields on washing about 5 dolis* per 100 poods.† Placer gold has also been found in the basins of the Talassa, Kurkursu, Bobokan, Bokair, and Yulmaral. In one of the smaller streams flowing into the Kurkursu during the investigation, as high a content as 70 dolis of gold per 100 poods of ground were recovered. On the river Yulmaral and its tributary the Tchintaschu the gold on being tested was found to amount to 12 dolis per 100 poods. The form of the gold found here is usually in thin flakes or fine dust. It is very seldom that it is found in the form of grains, though recently there have been cases when small nuggets have been recovered from the river Tchirtchik, near Britch-Mulla. Among the tributaries of the river Arys, gold has only been found on the Kulanu, but here the content has proved to be very disappointing, never exceeding 12 dolis per 100 poods.

In the Samarkand province gold has been found throughout the whole course of the river Yaravschan. It is in the form here of small grains and thin flakes. In all probability it finds its origin in the conglomerates which lie in some places on the banks of the river. Coming now to the well known district of Bochara, we find that gold washing is one of the industries of the natives along the valleys in the rivers of the Amu-darye system. However, the content of precious metal is small, so small that three or four men can scarcely earn more than 16 to 25c. per day, and were it not for the extreme poverty of the people it may safely be assumed they would not engage in this industry at all. There is a better gold content to be found in the conglomerate which reaches a considerable thickness in the valleys of the river Mjar-su, Yach-su (Tal-bar), and from their tributaries in the northeastern part of Balguan; also along the river Miyu in Kuiyavsky and along the rivers Sari-ob, Kilimbaya, and others in the northwestern parts of Darvasky and in the southeastern parts of the same neighborhood, along the river Tchavsoi, which is a tributary of the Rovnau. These conglomerates consist of pebbles and lumps of granite, syenite, diabase, quartz, and selenite rock combined with clay, sandstone, and cement. The gold is chiefly found in the cement and in the quartz shingle. The working of the alluvium by the natives is done in the open, underground operations being rarely attempted, though methods of working the gold are so primitive that practically half of it is lost in the waste. The form in which the gold is found in the places named is chiefly in flakes, and the content is 32 to 80 dolis per 100 poods. It has been known even to reach 1 zolotnik.*

The mining engineer, Zhoravko-Pokorsky, who has been very much occupied of late years in working the sands of Bochara, considers that the richest of the conglomerates is along the river Yach-su, near the village of Talbar, and along the Mazar-su and the upper reaches of the said river. During the nineties he began investigations in the depressions of these rivers, and then it was seen that in the upper beds the gold was very small, but immediately underneath, the gravel could be worked with profit, and the proportion of gold continued to grow with the depth. In 1904, out of 316,000 poods of ground, 5 funts† 17 zolotniks 95 dolis of gold were washed, and in 1905, out of 516,000 poods, 7 funts 12 zolotniks 78 dolis were washed, while during eight months of 1906 as much as 6 funts 27 zolotniks 9 dolis were washed ont of 720,000 poods of ground.

Another well known area is Ferghana. In the southern portion of the province of Ferghana three auriferous areas are known. In two of them, namely, on the rivers Kok-su, flowing into the Surchob, and on the Suok-su, flowing into the Muk-su, gold-bearing gravel is being worked, while on the third area near the river Polis the workings have for the present been abandoned. On the river Kok-su, about 18 versts from its mouth, gold sands are to be found which are being exhibited by Karatigins, and on the river Suok-su gold mines are found 15 versts above its mouth. The gold found is coarse. The bed of the Polis was previously exploited by Chinese. This area is just about the frontier between Russian territory and Bochara. In the first two deposits the road leads from the town of Skobelieff, named after the famous Russian general, through Utch-knrgan.

†1 pood = 36 pounds.
*1 doli = 0.6857 Troy grains.

*1 zolotnik = 65.8329 Troy grains.
†1 funt = 13.1665 Troy ounces.

From Skobelieff, which town, by the way, is dwindling in importance, to the sands on the river Kok-su, a distance of 156 versts farther through the road of Ters-agar, the road follows to Altyn-mazar, a distance of 61 versts, and on to the mouth of the Suok-su, about 15 versts above which the gold sands are found. The road to the third also leads from Altyn-mazar to the south, passes the glacier of Fedtchinko to the frontier area of Polis, from which point the sand is found at a distance of about five or six versts. At Altyn-mazar the production of gold per man does not exceed 6c. per day. The analysis of this gold gave 87% gold, 5.4 silver, and 7.2 copper. Farther down the Muk-su the known gold sands at the villages of Chodzha-tan and Tal-bar are to be found, and gravel is also worked on the stream Surchob, which is a tributary of the Muk-su. In this district it was proposed to begin investigations as far back as 1896, and concessions had been asked for this particular purpose, though for reasons not explained no effort has been made to carry on the work. Investigation for gold has likewise been carried on in the district of Namangan in the province of Ferghana along the river Santalasch, which is a tributary of the Tchotkol. In this place allotments for the purpose of exploiting gold deposits not far from the point where the Santalasch meets the Tchotkol were made as far back as 1908. The upper strata of the same are poor, but lower down there is a higher percentage of gold. Some samples gave as much as 2 zolotniks 18 dolis per 100 poods. Nevertheless, these promising beds of auriferous sands have not been worked up till the present.

The gold sands along the river Tentek, in the province of Semirctchensk, which flows into Lake Balchasch, have been considered particularly rich. In the area bordering on Kisyl-Togo, claims were made, but on proceeding to work it was found that the sands were too poor, and the same is the report made on the sands found along the river Argait. In the valley of the river Ketman the remains of gold workings previously abandoned by the Chinese have been found. On the Ketman work has been carried on at the Ivanovsky mines in the Dzharkent district and at the Grigorievsky mines in the same district on the river Bayankoi. In the early part of 1894 as much as 7 funts gold were obtained here and almost as much was found in 1895. The quantity obtained grew to over 8 funts in 1896. The Ivanovsky mine is being worked, and although data are not available up to date, the figure 1 funt 73 zolotniks of gold is given as that washed in 1907. Gold is also found in other rivers of the province of Semirctchensk, in the basin of the river Ili and on the right bank of its tributaries, the Choigos, Borochuzhir, Useku, and others, and in the basin of the lake Issyk-kul and the river Tekess, along the valleys of the rivers Ak-su, Dzhukka, about 30 versts to the north from the village of Krabuiaksky in the district of Kopalsky; along the river Tchyhol, 25 versts from the same village and in the boundary district of Balektasch, along the river Ak-tche, and in other places.

JOHANNESBURG, TRANSVAAL

Quarterly Reports.—Rodesian Output.

The batch of quarterly reports just issued by Rand gold mines for the three months ended June 30, clearly demonstrates the progress of the Main Reef mining industry and analyzes the achievement of individual mines. An examination of the various statements submitted to shareholders shows that during the period under review several companies earned substantially larger returns than in the preceding three months, while at the same time other mines, on account of labor shortage, labor inefficiency, and in one or two cases because of the poor grade of ore worked, performed less satisfactorily than they did in the previous quarter. Among the most important advances in profit earning is the improvement manifested in the returns of the great Wernher-Beit or Eckstein holdings known as the Crown Mines. In the June quarter the average monthly profits amounted to £101,513 as compared with £88,680 in the March period. The other great producer, the East Rand Proprietary Mines, did not do quite so well in the three months ended June 30 as in the quarter ended with March, but the earnings are maintained at well over £100,000 per month, or 50% on the issued capital of the company. The Robinson maintained its rate of earning and the Simmer & Jack improved its returns to a very substantial degree. The Village Main Reef Co.'s profits have improved to the extent of about £6000 per month, largely on account of more selective and careful mining. The Robinson Deep's earnings have been a little less satisfactory while the New Modderfontein's production and profits have steadily increased. This company controls one of the largest and most promising properties on the Witwatersrand. It has never yet been worked on a scale commensurate with its enormous potentialities but the company is now fast getting into its stride and it is worth noting that in the twelve months ended with June last, the company's mill crushed 523,950 tons as compared with 352,816 tons in the preceding year and increased its profit from £239,477 to £279,952. These are the largest and most important producers in these fields, their achievements may be taken to represent the trend of the whole industry, and an examination of their latest reports clearly shows that although the pinch of labor has been felt, the Rand, by reason of its inherent industrial stability, is not going to signalize the realization of its difficulties by a diminution of output. The production for the current year will in all probability be at least 2½% in excess of the yield for 1909.

The gold output of southern Rhodesia for the month of June was valued at £214,709 as compared with £224,888 in May. Contributions from coal and base-metal producers brought the total value of the mineral yield up to £238,916. The percentage decreases in the gold output of the country are attributable to scarcity of labor and also because many properties which have been producing for some months past have, in consequence of option holders pressing forward development work, had their stamps partly hung up. This does not, of course, really indicate any set-back. On the contrary it shows that in a few months' time the returns from these mines will be larger than hitherto.

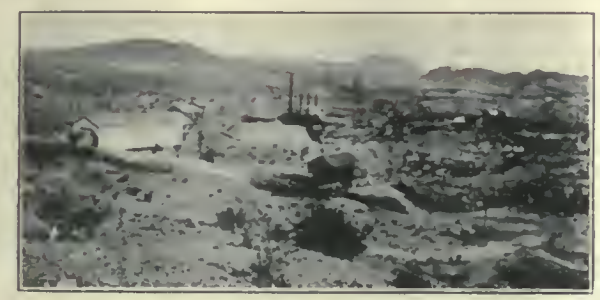
ALPINE, TEXAS

Terlingua District.—Presidio County.—Moriba. — El Paso Tin Mining & Smelter Company.

A large amount of new capital has been invested in quicksilver mines in the Terlingua district, eighty to ninety miles south of here, during the last few months, and the erection of two or three additional furnaces is planned. The Chisos Mining Co. continues to be the chief producer of quicksilver in the district, its monthly output of the metal averaging about $15,000 in value. Prospecting has been done recently on land situated some distance away from the proved cinnabar field and good claims are being opened. It is known that there are rich deposits of quicksilver across the Rio Grande in Mexico, fifteen to thirty miles from Terlingua. While a number of claims have been denounced on the other side of the river by Americans no development has as yet been done owing to the remoteness of the region from railroad transportation facilities. One of the great difficulties that is met with in the Terlingua district is the long distance that machinery and supplies must be hauled. It is ninety miles from Alpine to Terlingua, this being the nearest railroad point. It is reported that the Kansas City, Mexico & Orient railroad, which is to run through Alpine, may construct a branch line south through Terlingua into Mexico to a connection with the proposed railroad that is to be constructed between Monclova and Chihuahua. It is stated by men who are familiar with the territory which the proposed branch line would traverse that it would be the means of opening to development mineral districts of great richness. It would also penetrate the heart of the region of Texas and northern Mexico where the guayule shrub, from which rubber is now being manufactured, grows abundantly.

H. B. Young, of Shafter, and associates, who recently purchased a section of mineral land in the Shafter district of

Presidio county, are preparing to develop their holdings. This property adjoins the rich silver mines of the Presidio Mining Co. which have yielded more than $11,000,000 worth of silver during the last twenty-five years that they have been operated. These mines are still producing large quantities of rich ore. One of the claims upon the section that Mr. Young and associates have purchased was formerly worked under lease by the Presidio Mining Co. The ore was treated at Shafter in a 15-stamp mill, with pan amalgamation. William B. Phillips, of Austin, director of the bureau of economic geology of the University of Texas, recently made an examination of the property of Mr. Young and associates. He says concerning the mine: "The ore is essentially a silver chloride (horn-silver) held in a siliclous limestone. With the horn-silver there is associated more or less galena rich in silver, with a little sulphide of silver and, very rarely, thin sheets of native silver. The



Terlingua Mines, Texas.

average quality of the ore does not exceed 30 oz. in silver per ton, but richer material occurs in more or less isolated patches, even up to 200 oz., picked specimens assaying as high as 2300. The orebodies are chamber deposits in limestone. These chambers are frequently of great size and extent and yield large quantities of ore. Some of these chambers begin near the surface and continue to the 200 and 300-ft. levels, containing good ore all the way down. There are excellent opportunities for silver mining in the Shafter district. Successful operations have been conducted there for more than twenty-five years, and the character of the ore and its extent have been established beyond question."

SALT LAKE, UTAH

International Smelting & Refining Co. — New Converter Practice. — Sources of Ore Supply.

The plant of the International Smelting & Refining Co., at Tooele, Utah, is operating with four of its five reverberatory furnaces, and the fifth is being clayed and made ready for use. These furnaces are each 19 by 102 ft., four of which have connections with the battery of Sterling waste-heat boilers. The fact that the designs and specifications for the reverberatories were so skillfully made is said to be due to the efficiency and watchfulness of Joseph Jetté, of Anaconda, who had personal supervision of their construction. The four furnaces thus far have been smelting close to 560 tons daily of calcined ore from the roasters, producing a matte which runs 20 to 30% copper, the slags running approximately 40% silica, 48% FeO, and 4% lime. The five stands of converters, each 96 by 150 in., tilted by electrical equipment, are working satisfactorily. The lining is made up of siliclous ore and local clay. A sixth converter is being put in. The electric cranes work admirably. The principal one serves the converters in the usual manner; the smaller one serves to lift the converter slag to a plane at the top of the building, conveying it thence to any one of the reverberatory furnaces, pouring it through iron spouts. A. M. Day, general foreman of furnaces and converters, has developed a method of increasing the efficiency of copper converters by injecting into them through tuyere openings pulverized ore, concentrate, and fuel during the progress of the converting process. The metal-bearing material thus injected serves to enrich the matte derived from the furnaces, and the fuel thrown in intensifies the heat of the molten matte, increasing the calorific power. His method is undergoing trial at the Steptoe Valley plant at Smelter, Nevada, and it is probable that the process may be tested at this plant. The slag from the reverberatories is hauled to the slag dump in 22-ton cars, each car having electrical appliances for tilting the pot and discharging the slag. Every kind of haulage about the plant is by electric locomotives. The 32 McDougall roasters have capacity for calcining 40 tons each per day of ore, reducing the sulphur therein from 38 to 6%. At present only about 700 tons per day is being calcined. Thus far the supply of ore comes from the Highland Boy mine of the Utah Consolidated Copper Co., at Bingham, the transportation being over that company's aerial tramway, built by the Trenton Iron Works. However, the South Utah Mines & Smelters Co. is under contract to supply 100 tons of concentrate per day, which it is presumed may contain 13% copper, 30% iron, and high in silica. This property is at Newhouse, Beaver county, and it is understood that shipments are beginning. The operating staff comprises E. P. Mathewson, general manager; H. N. Thomson, superintendent: L. T. Sicka, mechanical superintendent; O. M. Kuchs, chief chemist; William Carder, in charge of sampling mill; Alexander Husband, cashier.

NEW YORK

Railroad Rate Case. — Mexican Mergers. — California Oil.— Cobalt Dividends.

The first break in the gloom which has held Wall Street shrouded in uncertainty so long came this week in the form of the decision of Special Master in Chancery Otis in the Minnesota railroad rate case, who holds the drastic railroad rate law, passed by the Minnesota legislature three years ago to be unconstitutional. While Wall Street realizes that corporate regulation will come, yet it has feared legislation passed in vindictive retaliatory spirit, and this decision is the first of importance nullifying such legislative action. While there has been a slackening of business throughout the country, yet conditions have become more acute and the stagnation more complete in Wall Street than elsewhere. The volume of trading is nominal save in those issues in which strong pools are known to operate, as in Steel and Reading. The political situation is one of the most important of market factors and the uncertainty in that quarter must continue several months longer. In mining markets there is little public interest.

Steps leading to the point where Ray Consolidated and Chino Copper are to become producers are being completed. The American Smelting & Refining Co. has taken a long-time contract to handle the Chino ores at the El Paso smelter. Ray Consolidated is to have a smelter, but its product and that of the Chino goes to the American Smelting & Refining Co.'s refinery at Perth Amboy, N. J. Contracts covering the marketing of the metal have been signed. Both the refinery at Perth Amboy and at the El Paso smelter are to be enlarged. The recently formed Arizona-Cananea Mines Corporation, owning 4000 acres adjoining the Greene-Cananea in Sonora, Mexico, has acquired the Boston-Miami which adjoins the Live Oak, just south and west of the Miami, the Inspiration, and the Keystone, in Globe district, Arizona. The deal also included the Montezuma claims which adjoin the Boston-Miami. It is said that an examination of conditions at Ely and at Salt Lake has convinced John D. Ryan that it will be necessary to equip the Giroux with a smelter, rather than stand the long haul from Ely to Tooele. The Mexican Metals Co. and the Arizpe Copper Co. are to be merged. Both properties are in the Cananea district, Sonora, Mexico. There is effort being made to interest the Eastern public in California oil propositions, but a lack of knowledge of the field and a lack of data on which to base any comparisons has made it difficult to accomplish anything. When Associated Oil was listed on the New York Stock Exchange it was thought it would prove a leader for a group of oil stocks; it has, however, been allowed to remain inactive, and there are many days in which no quotation is registered. Now,

however, there is a new leader for the oil group. The Texas company, headed by John W. Gates, which has grown to be a formidable rival of the Standard Oil Co., has applied for trading privileges for its $27,000,000 capital stock. A tin mine in the Piedmont district, Lincoln county, North Carolina, is the most recent mining venture in the South. A 6-ton mill is to be erected for the company which is known as the Piedmont Tin Co. The regular quarterly meetings of the Nipissing Mines Co. and the La Rose Con. were held this week and the regular quarterly dividends declared. In the case of Nipissing 7½%, La Rose 2%. While it is admitted that the matter of merger was discussed, it is said that conditions on the La Rose have so far improved that a new basis for consolidation would have to be reached. The Bailey Cobalt Mines Co. is installing a small experimental smelter, which will use oil as fuel. Two furnaces have been erected. The high-grade ore will be hand-sorted and smelted instead of shipped. There are many concentrators in Cobalt, but this will be the first smelter.

LOS ANGELES, CALIFORNIA

Mining Congress Assembles. — Pinchot's Address Well Received.— Lively Discussion of Oil and Conservation Matters.—California Oil Industry.—Clara Consolidated.—United Mines Company.

The thirteenth session of the American Mining Congress has been in session here this week. Extensive preparations had been made to care for the members and delegates and neither the citizens nor the visitors were disappointed. Many buildings were decorated and everywhere the city had a gala look. The Sierra Madre Club, the Chamber of Mines, and the Chamber of Commerce, joined in taking care of the visiting mining men. At the Club all members

Museum of Los Angeles Chamber of Mines, Germaine Building.

were made at home, and a reception was held Monday evening. Tuesday evening the Chamber of Commerce was host while at Wednesday noon the Chamber of Mines gave a luncheon at Hotel Alexandria. These and other festivities fully occupied the time between sessions of the Congress. The important features of Monday's session were the delivery of the presidential address by E. R. Buckley, and the discussion of Conservation by Gifford Pinchot. Mr. Buckley made a strong appeal to mining men to approach the problems of the industry in a thoughtful manner. He outlined the work and the field of the Congress in a manner that held the close attention of the large audience. Mr. Pinchot, who had prepared for the occasion by a special trip through the oil regions, first removed some misapprehensions as to just what the Conservationists were asking. He discussed the general subject briefly, insisting that conservation was but the application of business sense to the problems of the Nation, and that the whole people should be trusted to solve those problems. He maintained that conservation did not imply checking of development but that in order to secure the latter it was by no means necessary to give everything away for nothing. Specifically discussing the present situation in the oilfields, he stated that in his judgment (1) all public oil lands on which no locations had been made should remain in Government ownership; (2) that where locations had been made prior to withdrawal and development had been carried on under existing rules, patents should be granted; (3) aside from these cases the withdrawals ought to be maintained in order to get improved legislation; (4) the new law should provide for, *a* prospecting permits securing undisputed possession for three years if need be while making discovery, *b* for grant of title on discovery to last twenty-five years, or longer, if need be, at a royalty sufficiently low not to discourage development; (5) in event such legislation could not be obtained withdrawals in areas where there were Southern Pacific lands should be vacated as likely to be more beneficial to the railway than the general public; (6) that the Government would fail in its duty if it did not exhaust every legal means to recover title to mineral lands now held by the Southern Pacific in the oilfields. His speech was well received being evidently much less radical than had been anticipated. Through Tuesday the discussion of the oil land situation was continued with S. C. Graham and T. A. O'Donnell as leaders respectively of the Progressives and Standpatters.

The Union Oil Co. is adding two 70-hp. boilers to its main water station at Hazelton; a 6-in. main will carry water to the different centres of operation. A 6-in. water system will be carried through the west side properties. A battery of three 70-hp. boilers is being installed on the Sage property to handle the output of the two water wells recently brought in. The Union company is working between 400 and 500 men on the west side. Owing to the full storage and small runs, development work in the Kern River field is not being pushed. New work is being delayed until conditions become better. The Kern Westside Oil Co., operating on the western edge of the Kern River field, has a well down 400 ft. with 16-in. casing. Although this vicinity has been prospected at shallow depth without favorable results, the officials of the Kern Westside company believe that oil will be found if sufficient depth is attained. The Ethel D. Co., at Maricopa, brought in two gushers last week. After spouting for a few hours the wells, No. 6 and 9, settled down to a flow of 700 to 1200 bbl. per day respectively. The Western Minerals Co., owning about 4000 acres of oil lands directly south of Maricopa, recently brought in a well at 1650 ft., the oil being a fine light product testing 31°. This is the lightest grade oil encountered in the Midway-Maricopa field. The first sand in this well was encountered at 1120 ft., the oil testing 19°; the second sand was encountered at 1340 ft., at which depth the oil tested 24°. The discovery of the third sand, yielding the light oil, has produced something of a boom in the district.

S. A. Guiberson, Jr., a member of the executive committee of the Oil Producers' Agency, is quoted as stating that every effort is being made to sell Agency oil, and that if the proper price can be had from the Associated, the product will go to that marketing company. Mr. Guiberson stated also that he could see no reason why the Western Oil Producers' Association and the California Oilmen's Association should not be consolidated, now that the dissension in the ranks of the former organization has been overcome.

The smelter of the Clara Consolidated Gold & Copper Mining Co., at Swansea, Yuma county, Arizona, has again been blown in. The management states that everything now favors continuous operation. An ample supply of ore is developed at Swansea and about two carloads is being received weekly from the Mudersbach property south of Bouse. This property was recently purchased by George Mitchell, president of the Clara company. Advice has been received at the Clara offices that the company has been awarded two first prizes at the Brussels Exposition; one for its mineral exhibit and one for the model of the smelting plant. The United Mines Co. will within the next 30 days begin operations on what was formerly known as the Golden Cross mines, at Tumco, Imperial county, California. The company is now awaiting the completion of a 6-in. pipe line from the Colorado river; this will be 12 miles long when completed. The property is equipped with a 40 and a 100-stamp mill. At the start only 50 stamps will be operated. The ore is free-milling, and for the present no cyaniding will be attempted; later, however, after the completion of extensive experiments, a cyanide annex may be erected.

General Mining News

ARIZONA

COCHISE COUNTY

Work at the Cole shaft of the Superior & Pittsburg Copper Co., commonly known as the South Bisbee ground, has been stoped indefinitely and most of the miners transferred to the other properties of the company.——The Calumet & Arizona, in the Courtland district, has also suspended for the time being.——Churn-drilling on the second hole of the Great Western company has been started.

GILA COUNTY

(Special Correspondence).—The local management of the Little Miami Copper Mines Co. is expecting orders to begin development at the inclined shaft on the 17 claims bought some months ago from the Cole Development Co. and situated 15 miles west of Miami. In the Cole mine there is much ore of both high and low grade exposed and the dump at the main shaft contains 3000 tons of ore averaging 4% copper. Unwatering the shaft and lower level has been commenced. Richard Fleming is superintendent and general manager.——E. C. O'Keefe, a director in the newly organized Globe, Arizona, and El Paso Mining & Smelting Co., arrived in this district September 21 to take up options held by the company on 44 claims five miles north of Miami, near Sleeping Beauty mountain. According to the terms of the options development must be started by October 1, 1910, and $25,000 must be expended in operations within one year.——Stockholders of the Live Oak Development Co., in a meeting held at Bisbee, agreed to increase the directorate from five to nine. The change will be made within 30 days, or as soon as the necessary amendment to the constitution can be prepared and published. Among the additional directors will be George J. Maas, of Negaunee; George F. Ruex, of Ishpeming, Mich.; and George Piper, of Duluth, Minn. So far as can be ascertained from the management in this district, the Inspiration Copper Co. has not yet selected a site for its proposed 5000-ton concentrator. The initial tests of ore will be commenced in the experimental mill within three weeks.——W. B. Eaton, president, and C. W. Pritchett, general manager of the Cactus Copper Co. and the Summit Mining Co., are in Miami district inspecting both mines.

Miami, September 24.

MOHAVE COUNTY

(Special Correspondence).—George Mitchell, president and general manager, reports from Swansea that the operation of the Clara Consolidated Gold & Copper Mining Co.'s smelter will be resumed after a shut-down for repairs and additions.

Los Angeles, September 24.

(Special Correspondence).—Shipments of gold bullion from the Gold Road and Tom Reed mines this week set new records of production for these properties. The Gold Road output was valued at $30,000 and represents 9 days' run, and two bars of gold from the Tom Reed, weighing 250 lb., worth a little over $50,000, are the result of a three weeks' run. At the Tom Reed with the recent addition of another tube-mill, the average amount of ore treated is less than 60 tons per day. At the Gold Road two more Chilean mills and another compressor are nearly in place but will not be put into operation until more power is available at the Kingman plant. With the new Chilean mills and changing from sand leaching to sliming and filtration the mill is expected to treat 300 tons daily. It is estimated that there are 100,000 tons of ore broken in the stopes and about five years' supply blocked out in reserve. The Tom Reed has about two years' run in reserve and the new work on the 500-ft. level is proving a large and rich orebody. All ore milled to date has averaged a little over $40 per ton and that now being treated is better than $60 ore. In the Ruth mine, in Silver Creek district, a new working shaft has been started 400 ft. west from the main shaft. Dan Bosqui, mill superintendent of the Gold Road, has completed a series of cyanide tests of the Ruth ore and Mr. Van Deman, manager, is in Los Angeles arranging for the erection of a mill and cyanide plant along the lines of the Gold Road works. In Union Pass district, a group of prospects owned by Holmes & Warner, at Secret Pass, several miles west from Union Pass, has been bonded by Loftus & Davis of the Goldfield-Round Mountain Mining Co. Three shifts are sinking a shaft. L. R. Scott is superintendent. Good headway is being made in the erection of the 100-ton mill and cyanide plant at the Tragedy mine, owned by the Frisco Mines & Power Co., and it should be in operation by November 1. Marshall D. Draper, of Denver, has been examining prospects in this district and in the Cerbat range for Colorado men. Concrete foundations for another unit to the local power plant, doubling its capacity, are completed and the work of erection started. The management expects to have the additional equipment running by the first of the year.

Kingman, September 22.

PINAL COUNTY

The main shaft of the old Silver Queen property, at Superior, is down 700 ft. and a station is being cut. The shaft is vertical and as soon as the station is completed a crosscut will be started for the vein which is about 300 ft. north of the shaft at this depth.——A prospect shaft at the Carney claims in the Superstition mountains is down 15 ft. exposing a 2-ft. vein that assays $27 gold with 17% copper.

YUMA COUNTY

Active work is under way at the Wardell-Osborne property east of Parker and the road to town is being put in good condition so ore may be shipped to the Swansea, or Needles, smelter at an early date. There are a number of good showings on the claims, considerable of the development having been done in ore.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence).—The Amador Keystone Gold Mining Co. (M. Jasper McDonald), has asked the court to appoint a receiver for the California Consolidated Mines Co., which at present controls the Keystone group of mines at Amador City, and the Wildman-Mahoney group at Sutter Creek.——The Alpine mine, situated in the northern part of the village of Plymouth, and which was worked more than twenty years ago, is being reopened. The former operators worked to a depth of several hundred feet. This new enterprise is having a stimulating effect on the mining industry in northern Amador county.

Jackson, September 24.

LASSEN COUNTY

Nearly all of the force of 150 men at the Hayden Hill mines (Golden Eagle group), have been laid off, and it is now reported that little work will be done before next spring.

NEVADA COUNTY

(Special Correspondence).—The North Star Mines Co. has purchased the Pratt and Dubuque claims, which adjoin the North Star holdings, and comprise four acres. The company is vigorously developing its claims on Cincinnati Flat and opening considerable territory. At the main Central workings the usual work is progressing from the lower levels. The company recently declared its third dividend for the year, amounting to $100,000. At the Empire the construction of the cyanide plant is rapidly nearing completion. Developments are satisfactory in the mine, and 40 stamps are operating constantly. It is understood that monthly production is running $50,000 to $75,000.——The recently opened orebody at the Pennsylvania continues to show a good grade of quartz.——The raise from the adit at the Jenny Lind appears to be near the channel.——A compressor has been installed at the Andy Fitz, near Moore's Flat, and 1200 ft. of flume and 800 ft. of pipe completed.——It is possible that operations may be resumed at the Conlan mine before the end of the year. H. G. A. Brunnier, the manager, expects to arrive early in October and will en-

deavor to settle the financial obligations of the company. ——Operations have been resumed at the Golden Gate.—— The recent rains have apparently eliminated all danger of a water shortage in Nevada county. Companies that were preparing to curtail operations are again operating as usual.

Grass Valley, September 26.

The North Star Mines Co. paid its third dividend of 4% recently, making a total of $300,000 thus far this year. The company is constructing a number of concrete sets that will be placed in the shaft and in the drifts of the mine. The timbers will be allowed 30 days on the surface to set before being placed in the mine.——A number of stockholders visited the Cassidy mine in the Grass Valley district and have expressed themselves as being well pleased with the progress in development.——Considerable trouble is being experienced at the Prudential in obtaining a steady supply of power and it is thought that it will take over a month to unwater the shaft.——The recent high water on the Yuba river flooded the channel at the Golden Dream workings stoping the work temporarily. These are being pumped out and operations will be continued till the winter rains begin.

PLACER COUNTY

George A. Tubb has purchased the Wollaster quartz claim which adjoins the Red Bird on the west, and was at one time known as the Red Bird No. 3.——The dredge operating on Bear River has suspended operations as the ground is too deep to be economically worked by the machine as now arranged. It will be repaired and changed, so as to continue operations in the spring.

SIERRA COUNTY

(Special Correspondence).—The shaft on the Poker Flat gravel mine is down 330 ft. and into the washed gravel. A large tract of land, supposed to cover the channel, has recently been acquired by this company by location.——The Phelan brothers, of San Francisco, have started work on the Commodore group three miles south of Sierra City. The group consists of six gravel claims and the company is sinking to bedrock on the Klondyke claim. C. B. Conlin is in charge.——The litigation over the Mountaineer mine has been settled. The mine is 7 miles northeast of Sierra City, and is equipped with 10-stamp mill. J. M. Shinn, of New York, retains the mine, and C. R. Thompson and associates take all buildings and machinery on the property. The compressor, mill, and buildings are to be moved to the Colombo mine.——Work on the lower adit of the Colombo is progressing rapidly, being in 120 ft.——The shaft on the Monarch mine, under bond to C. R. Thompson, is down 75 ft. and a horse-whim is used for hoisting.—— Lessees on the Keystone mine discontinued work after the last mill run which was not satisfactory.——The Hayes Consolidated Mining Co., operating 2½ miles from Sierra City, on the Downieville road, has men opening the mine, which has been closed down for a number of years. It is equipped with a 10-stamp mill. Extensive prospecting and development will be done on the present adit level. S. J. Van Syckel is manager, and William Barker superintendent. ——The Sierra Buttes mine has 35 men at work and the 10-stamp mill is running three shifts. A 10-drill compressor has been ordered and extensive development is to be done. ——The Middle Yuba Mining Co., 10½ miles west of Sierra City, has practically finished work for the summer. This company sank through the gravel to bedrock and has driven 100 ft. along the bedrock. E. J. Hayden has charge of the work.——Bids have been advertised for by the county clerk for the construction of the road from Sierra City to Gold Lake to connect at the county line with the Plumas county road. The road will only require 7.4 miles of building, the remainder, 13 miles, having already been completed.

Sierra City, September 26.

TRINITY COUNTY

(Special Correspondence).—The 200-ton cyanide mill and power plant of the Trinity Gold Mining & Reduction Co., near Carrville, is rapidly nearing completion. Most of the machinery is installed in the mill and it is expected to be ready for operation on November 1. The company is bringing in supplies for the winter, such as lime, cyanide, and zinc dust, in anticipation of bad weather later in the fall. A combination steel and wood bridge of 126-ft. span is being erected over the Trinity river just below Carrville. This bridge will be completed in 15 days and will afford easy access to the mine in all conditions of weather. This is a private enterprise and the company received no assistance from the county or Forest Service. The work on the power plant and flume is proceeding rapidly. The flume is completed to station 6700 and only 2300 ft. remains to be finished. The work of laying this flume is proceeding at a rate of 175 ft. per day. The flume is 3 by 4 ft. cross-section and will carry 2000 in. of water. The intake pipe for the turbine is on the ground and the concrete foundations for the turbine are completed. The power transmission line is up and electricians are wiring the buildings. The company's sawmill has cut 1,400,000 ft. of lumber which has been used in construction work. This plant when finished, will be one of the most modern and complete in the State.

Carrville, September 24.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—E. J. Butts, manager for the Big Indian Mining Co., is employing men in constructing a road to the mine. A new adit is to be driven and machinery will be purchased.——The machinery at the holdings of the Bard Creek Mining Co. will be put in operation next Monday. Work in the lower adit will then be resumed. F. Nelson is manager.——The buildings at the Oriental adit on Lincoln mountain have been completed and the adit is advancing. James Beshears made a test shipment of 100 lb. of ore from the Esconado vein on Lincoln mountain that brought a settlement at the rate of 3.10 oz. gold to the ton. A mining engineer from Colorado Springs has been making an examination of the property during the past week.——The shaft being sunk from the Capital adit on the Aetna vein has reached a depth of 50 ft. A fine streak of ore has been followed the entire distance.——Edwin Clark, owner of the National group in West Argentine district, has men at work. The adit is being driven ahead and a streak of galena is showing that carries 75% lead.

Georgetown, September 22.

GILPIN COUNTY

(Special Correspondence).—A rich discovery has been made in the Hughesville silver district in the eastern extension of the Hard Money mine. The ore is said to be 3 ft. wide and will carry an average of 50 oz. silver to the ton. There is also a small streak of ore that mills as high as 400 oz. silver. P. J. Hughes is owner.——A shipment of ore was made last week from the War Dance mine that brought 11.60 oz. gold and 17 oz. silver to the ton.——The Sunnyside mine in the Hughesville district is being developed by the owner, P. J. Hughes. Ore is showing in the bottom of the 25-ft. shaft that is worth 150 oz. silver to the ton.——A contract has been awarded by L. Sternberger at Camp Clifford to drive the Washington adit 600 ft.——Mitchell & Co., leasing on the Gulch mine, is shipping ore from the 420-ft. level.——The Columbia adit up Hamlin gulch is being driven steadily forward. Ore was recently encountered that shows fair value in gold and silver.

Central City, September 23.

IDAHO

BLAINE COUNTY

(Special Correspondence).—James Forester and Read E. Miller while examining the Fallert and McCowin group of mining claims on Badger creek near Clyde, found the mineral showings far better than anticipated. On the south claim of the McCowin there are numerous small veins and stringers of steel galena, which in several place shave been cut by short shafts and adits. These stringers of ore occur every few feet for a total width from 5 to 50 ft. On

the claim extending northward and running parallel to the one just mentioned, there are large quantities of lead float varying in size from small pieces of steel galena to one boulder, of which particular notice was taken, of sand carbonate weighing in the neighborhood of 500 lb. This is all in a radius of 150 ft. and is considered an exceptional surface showing. The Fallert property is a promising prospect; there is a 60-ft. drift on the vein which is five feet wide on the surface; 30 ft. in there is a shoot of ore. Mr. Forester and Mr. Miller have been operating the Fallert claims for several months though considerable repair work had to be done before development could be commenced. The drift has been driven 50 ft. farther, there is a carload of high-grade ore on the dump, and several more have been blocked out preparatory to shipping. They expect to make the first shipment within ten days and continue shipping all winter. Recently a new drift has been commenced 75 ft. below adit A and a shoot of high-grade lead-silver ore three feet wide has been opened that extends the full length of a 40-ft. winze. At present there are only 10 men at work on the property, but as soon as development is begun on the McCowin claims this force will be increased considerably. Good progress is being made in the construction work, the dormatories and other surface buildings are nearing completion. A surface ore-chute, flume, dam, and washer were completed some time ago.

Clyde, September 23.

BOISE COUNTY

(Special Correspondence).—The concentrating and magnetic separating plant of the Centerville Mine & Milling Co., at Centerville, was destroyed by fire two weeks ago, and it is given out that the plant is to be rebuilt. The work here was recovering monazite from old placer tailing along the streams.

Centerville, September 22.

ELMORE COUNTY

(Special Correspondence).—The Atlanta Mines Co., owner of the Monarch mine and mill at Atlanta, is controlled by T. N. Barnesdall, of Pittsburg, Pa. Dan Kirby is general superintendent. A small force of miners has been employed on development, but now 75 to 100 men are being put on to operate mine and mill, the capacity of the latter being 150 tons per day. After some changes the milling plant now provides for coarse-roll crushing, pulverizing in 5 Huntington mills, amalgamating on plates below the Huntingtons, concentrating on Johnston vanners. The concentrate is roasted and treated by cyanidation. By amalgamation a recovery of 25 to 30% of the gold and silver is made; concentration effects a reduction of 40 to 1, the product containing 5 to 6 oz. gold and 100 oz. silver per ton, in iron pyrite and pyrrhotite. Cyanidation is performed in ordinary leaching vats. The ore contains over 90% silica. By adopting this method the haulage of concentrate to the railroad at Mountain Home, a distance of 80 miles, will be avoided. One feature of the equipment is an aerial tramway, 9800 ft. long, which is said to be in good order. The Minerva mine and mill, situated close to Atlanta, are operating successfully; the ore being free-milling, is treated in a 20-stamp mill with amalgamating plates.

Atlanta, September 22.

(Special Correspondence).—John F. Leland has returned to Spokane from an inspection of the Idaho Gold & Radium Mining Co.'s property in the Leonia district and says the company has 640 acres of gold-bearing gravel with sufficient water to work four nozzles. The average depth of gravel exceeds 150 ft., and tests give from a few cents to $1.60 in gold per cubic yard. There are also three gold-bearing veins, ranging from 2 to 15 ft. in width, which are thought to be the source of much of the gold in the gulch. Ore shipped from an extension of one of these veins by the carload returned $160 per ton in gold and copper. There is timber enough to meet all present demands. A sawmill will soon be in place. The property can be worked seven months in the year. It is within half a day's ride of Spokane, and within an hour's ride of a railway station.

Spokane, September 23.

SHOSHONE COUNTY

(Special Correspondence).—M. Baumgartner, of Spokane, president of the Liston Mining Co., reports reconstruction of the camp in the Coeur d'Alene proceeding rapidly. A blacksmith shop and quarters for the men are under way and a compressor house will follow. A compressor and machine-drills will be installed. In the meantime hand-drills are being used.

Wardner, September 22.

NEVADA

ELKO COUNTY

(Special Correspondence).—The 4-M lease has shipped two wagon-loads of high-grade ore. They have been trying for several weeks to have this ore taken out, but none of the ranchers would haul any ore for less than $50 per ton, for the 90 miles' haul to the railroad. This high rate for freight either in or out of the camp is one of the things that is holding the camp back. The Jarbidge Commercial Club has taken up the matter of building a road to the south to connect with the Southern Pacific and Western Pacific at Deeth. An engineer reports that it is feasible to build this road and that it will give the camp a 65-mile haul to the railroad. From Charleston to Deeth there is a fine road over which autos can make the run in two to three hours. This road will give the camp much lower freight rates, and supplies can be bought much cheaper at Deeth or Elko than at Twin Falls. Work will be pushed on this road so that the camp may have winter communication with the outside as the Twin Falls road cannot be used to advantage during the winter. The new road will permit autos to come into camp and will be available for transporting heavy machinery. Besides the 4-M lease, there are several other properties which have shipping ore, the Bluster, Rock Creek, and Success claims near the Pick and Shovel; the Altitude, Windy, and Victoria claims in the Second Crater; the Arkansas in the Third Crater; and the Windy Point in the Fifth Crater. The Good Luck tunnel is in 50 ft., running along the hanging wall of the vein; another 50 ft. will bring them under the outcrop. The vein shows good average value with high-grade spots and streaks of iron pyrite. An opening has been made on the vein across the gulch where it shows 9 ft. wide. The Amazon-Rainbow adit is in 80 ft., and a car and track were recently put in. It has 50 ft. to run to cut the main vein; the small cross-vein which was being followed took a sharp turn to the south out of the tunnel and they are swinging the tunnel to get back to it. When they encounter the main vein it will be at a depth of 125 ft. The Pavlak tunnel is in 380 ft. and the character of the rock indicates that the vein is not far away. This tunnel will tap the vein at a depth of 400 ft. and from the showing in the shaft above and in the two leases on each side there is reason to believe that the vein will be large and rich on this level. The Clark-Fletcher lease on the North Star has the lower tunnel in 160 ft. and the presence of numerous small seams of quartz which pan well, indicates that they are near the vein. This tunnel is 100 ft. below the Bourne tunnel. Mr. Fletcher says that if the vein shows as well on this level as above, he will put in a mill. W. W. Williams has opened the vein in three places on the Red Bird claim, it shows from 4 to 6 ft. wide and pans well in free gold. This vein is 600 ft. east of the Pavlak vein and can be traced across the Joe and Guess claims into Bonanza gulch. The Rock Creek vein in 15 ft. has increased from 6 in. to over 2 ft. and the ore pans as well as any in the camp. The Bluster-Mint-Scenic case is on trial in the Elko court. This vein has the best showing yet opened, both as to size and value of the ore. Two tons of high-grade ore have been sacked with practically no work going on. With uninterrupted work this mine would soon be a shipper. The Stray Dog and Red Rooster claims in Gorge gulch are beginning to show good value. These claims are just

over the ridge southerly from the Bluster and on the same vein, which can be traced south across Snowslide gulch. The Arkansas vein, in the Third Crater, over the saddle at the head of Snowslide, has widened to 5 ft. The whole vein pans well and there is some high-grade ore. The Ozark vein south of Dry gulch which shows an average of $4 for 25 ft. in width has been opened by a short adit and the value has increased to $9 in the adit. The Estes claim on the west side of the river, a short distance south of the Amazon, is being opened by the Jarbidge Estes Mining Co. The vein is several feet wide and 15 in. on the hanging wall side pans well. The Tacoma company, west of town is preparing for steady work. It has one of the largest outcrops of quartz in camp. The shaft is down 40 ft. and the adit is in the same distance. They are driving to open the vein at a depth of 100 ft. when they expect to have sufficient ore exposed to warrant the erection of a mill. The National claim has an adit in 100 ft. with 50 ft. farther to run to cut the vein at 90-ft. depth. The camp has heretofore had no regular mail service.

Jarbidge, September 24.

LYON COUNTY

(Special Correspondence).—The Mason Valley Mines Co. has engineers at work on preliminaries for its smelting plant at Wabuska. Grading for foundations is in progress, and a railroad spur is being built to the site. The work of designing the plant has been going on for some time in the Salt Lake office of J. Labarthe, who is at the head of the company's smelting department. Mr. Labarthe states that the initial plant will have a sampling mill with a capacity of 100 tons per hour, two blast-furnaces, each 44 in. by 25 ft., and two stands of converters. It is also probable that a small reverberatory will be built for the purpose of smelting the fine ore and fine dust. It is anticipated the Mason Valley mine will supply from 400 to 500 tons of ore daily to the plant, and the Nevada-Douglas company is under contract to supply 350 tons per day. Both mines are in the Yerington district, which has been frequently described in this paper.

Salt Lake, September 24.

NYE COUNTY

(Special Correspondence).—The 100-ton mill of the Bonnie Clare Co. is in operation. In addition to the quartz coming from the Rattlesnake and Corbett mines of this company, a fair amount of custom ore is being treated.——The various leases on Tramp Con. are making steady shipments of rich ore. The veins on the Denver claim are showing well.——Most of the suits affecting mining companies at Manhattan have been stricken from the court calendars in accordance with the request of the warring interests. In practically every instance owners are showing a disposition to settle their differences out of court. The settlement of litigation by the Dexter, Jumping Jack, and Stray Dog companies has had a good effect on local conditions.——A vein of free-gold quartz has been opened in the northern part of Manhattan district by T. Baker, John Sherman, and James Desmond, surface work showing ore running over $20 per ton.——At Tonopah the enlargement of the Belmont shaft to three compartments has been completed from surface to the 1100-ft. point. A temporary hoist has been installed and guides are being placed in position. It is expected to have the new hoist in operation about the middle of October. The new ore-bins have been completed and covered with corrugated iron.——At the Tonopah Extension stoping is under way at the 400, 500, and 600-ft. levels. A cross-cut is being run on the 500-ft. level to intersect the orebodies developed above.

Rhyolite, September 21.

UTAH

BOX ELDER COUNTY

(Special Correspondence).—The Salt Lake Copper Co., under the management of W. B. Fisher, is shipping 140 tons per day of iron ore to the plant of the U. S. Smelting, Refining & Mining Co., at Midvale, for use as flux, and at present is mining no copper ore. The iron ore (hematite), is taken from vein outcrop.

Salt Lake, September 23.

SUMMIT COUNTY

(Special Correspondence).—The American Exploration Co., controlled by F. V. Bodfish and associates, of Colorado, has taken a 5-year lease on the American Flag mine at Park City, and has begun operations with 15 men, under direction of Mr. Bodfish. The lease was given by George H. Rathman and associates.

Salt Lake, September 23.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—With shipments during the past week amounting to 1300 tons of ore the Rawhide mine, at Phoenix, controlled by the British Columbia Copper Co., started shipping to the Greenwood smelter. Shipments will be gradually augmented and it is expected that 150 men will be employed in the course of a few months. The buildings now going up to replace those recently burned at the No. 3 adit of the Granby mines, are of brick, steel, and cement. The shipments of ore from the Granby mines during the last two weeks have dropped below the normal amount during the year, because the company has decided to curtail output until such time as the copper market strengthens. Jay P. Graves, of Spokane, general manager for the Granby company, has gone to New York to attend the general meeting of the company there October 4. Things are progressing well at the No. 7 mine of the Consolidated company at Central camp, and it is expected that the mine will be on a shipping basis some time next month. It is rumored that the Consolidated company is looking for mines on the west fork of Kettle river, where there are some good copper properties.——Work has been started on the Princeton-Chilliwack Coal Co.'s property at Princeton. A shaft 4½ by 7 ft. will be sunk. The ore shipments from the Boundary district for the week ended September 17, and for the year to that date, were as follows:

Mine	Week, Tons.	Year. Tons.
Granby mines	16,530	839,959
Jackpot	618	8,258
Mother Lode	8,653	254,453
Nickel Plate (concentrate)	38	539
Rawhide	1,300	1,300
Snowshoe	2,125	116,091

Phoenix, September 22.

(Special Correspondence).—The shipments of ore and concentrate from the Slocan-Kootenay mining district for the week ended September 17 and for the year to that date were as follows:

Mine.	Week, Tons.	Year, Tons.
Emerald	34	1,362
Enterprise	23	44
Highland (concentrate)	45	147
Queen (concentrate)	39	505
Richmond-Eureka	22	3,054
Ruth	36	422
St. Eugene (concentrate)	150	11,226
Sullivan mine	937	12,350
Slocan Star	30	30
District mills	4,500	187,800

Nelson, September 22.

(Special Correspondence).—N. Hanson, the lessee of the Mayflower mine in the South Belt, has opened two veins. The property looks promising. Work is progressing steadily on the Consolidated group and shipments are up to normal. While heavier shipments could be made the management is inclined to keep them low with the copper market in its present condition. Two new veins have been opened in the Iron Mask mine of this group. The Granby company will soon be in a position to commence work on the Cliff property.

Rossland, September 22.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. F. JONES is now at Republic, Washington.

R. B. LAMB has returned to New York from Cobalt.

F. R. LOWELL has returned to Berkeley from Siberia.

J. D. HUBBARD has returned to San Francisco from the East.

ARTHUR G. BLAKE has left San Francisco for Nome, Alaska.

W. H. STORMS has returned to San Francisco from a trip to Colorado.

HOWLAND BANCROFT is in Arizona engaged in geological work at Ray.

H. W. TURNER is in Cho-sen (Korea), Japan, examining copper mines.

BERTRAM HUNT has returned to San Francisco from British Columbia.

DYKE V. KEEDY is in Nova Scotia making examinations of copper property.

CARL F. DIETZ has left Boston for Colorado and New Mexico mining districts.

MORTON WEBBER has returned to New York after a two months' vacation in Europe.

MARSHALL B. DRAPER, of Denver, was recently in Mohave county, Arizona, inspecting mines.

ATHOL F. MCEWEN, of Duluth, Minnesota, is in California, making mine examinations.

K. TSUJIMOTO is visiting smelting plants in this country and will be in New York October 15.

J. B. TYRRELL, of Toronto, Canada, returned on the *Mauritania* from a short visit to London.

K. C. PARRISH has returned from Colombia, South America, and will be in Des Moines, Iowa, until November 1.

Henry B. Hovland, of Duluth, Minnesota, was recently in Globe, Arizona, where he has large interests, being president of the Live Oak company.

W. H. RADFORD has left Siberia and will arrive in San Francisco about the middle of October. The sympathy of his many friends is extended to him in his recent bereavement, the death of his son at Los Angeles.

T. H. JENKS and W. T. DUMBLETON have entered into partnership as consulting mining engineers with offices in the McPhee building, Denver, Colorado. Mr. Jenks is temporarily at White Pine, Gunnison county, Colorado. Mr. Dumbleton sailed for England on professional business September 7, on the *Lusitania*.

The San Francisco Section of the Mining and Metallurgical Society will tender a complimentary subscription dinner to J. A. HOLMES, the newly appointed director of the U. S. Bureau of Mines, at the Palace Hotel, October 6.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

H. W., Rhyolite, Nevada: No. 1, hornblende gneiss or amphibolite; No. 2, crystalline limestone with limonite; No. 3, schist with a small amount of pyrite; No. 4, granite coated with a thin layer of dolomite; No. 5, granite.

E. A. G., Fort Bidwell, California: The rose and amethystine shades of quartz have been generally ascribed to the presence of minute quantity of manganese. It has been discovered that titanium will also produce violet tints, and since both of these elements are rather prevalent in siliceous rocks the purple color of the specimen may be due to either. It is not an indication of any precious metal.

CURRENT PRICES FOR ORES AND MINERALS

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco.

	Min.	Max.
Antimony ore, 50%, per ton	$25.00	$35.00
Arsenic, white, refined, per lb	0.03	0.03½
Arsenic, red, refined, per lb	0.08	0.09
Asbestos, according to length and quality of fibre, per ton	100.00	350.00
Asbestos, lower grades, per ton	10.00	100.00
Asphaltum, refined, per ton	15.00	20.00
Barium carbonate, precipitated, per ton	42.50	45.00
Barium chloride, commercial, per ton	42.50	47.50
Barium sulphate (barytes), prepared, ton	20.00	30.00
Bismuth ore, 10% upward, per ton	75.00	upward
Chrome ore, according to quality, per ton	5.00	15.00
China clay, per ton	15.00	20.00
Cobalt metal, refined, f.o.b. London, per lb	2.50	
Coke, foundry, per 2240 lb	15.00	17.50
Diamonds:		
Borts, according to size and quality, per carat	2.00	15.00
Carbons, according to size and quality, per carat	75.00	100.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Bauxite, per M	175.00	200.00
Magnesite, per M	200.00	250.00
Silica, per M	47.50	
Flint pebbles for tube-mills, per 2240 lb	15.00	25.00
Fluorspar, per ton	8.00	15.00
Fullers earth, according to quality, per ton	10.00	30.00
Gilsonite, per ton	32.50	45.00
Graphite:		
Amorphous, per lb	0.01	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	2.50	5.00
Infusorial earth, per ton	5.00	15.00
Magnesite, crude, per ton	5.00	7.50
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	45.00	125.00
Mica, according to size and quality, per lb	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per lb	0.02½	0.03½
Platinum, native, crude, per oz	20.00	25.00
Quicksilver, per flask (75 lb.)	45.00	48.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 70%, per ton	400.00	450.00
Tungsten ore, 65%, per ton	525.00	575.00
Vanadium ore, 15%, per ton	100.00	125.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	15.00	20.00
Zinc dust, 90% minimum, per 100 lb	7.50	9.50
Zinc oxide, per 100 lb	7.50	8.50

JOPLIN LEAD AND ZINC PRICES.

The *News-Herald* gives the following on the lead-zinc situation in that district for the week ended September 24, 1910. There has been a strong demand for ore of all grades, the best blende selling at $48 per ton, the highest price since March 26. Many mines that had been idle have resumed operations, and others are making preparations to do so. At St. Louis spelter has fallen from $5.50 to $5.27½, which indicates that stimulated production will have a direct effect on price, though it is expected to remain at about the latter quotation. Calamine, 40%, sold for $22 to $26, the better grades going as high as $30. Lead ore remained unchanged at $54 to $56. Pig lead sold at $4.27½. Joplin shipped, blende, $44,562; calamine, $384; lead, $5995; total, $50,941. Webb City, blende, $94,458; lead, $25,141; total, $119,599. Galena, blende, $25,872; lead, $3108; total, $28,980. Quapaw, blende, $5576. Alba-Neck City, blende, $10,836. Aurora, blende, $2583; calamine, $1428; lead, $1782; total, $5793. Zincite, blende, $3780. Miami, blende, $5713; lead, $1265; total, $6978. Seneca, calamine, $720. Total of other districts, $37,625. Grand total, $353,082.

TABLE OF CONTENTS

EDITORIAL

AN examination for the position of mining engineer will be held by the United States Civil Service Commission, November 9, to furnish an eligible list for appointment to positions in the Bureau of Mines. Candidates should apply to the United States Civil Service Commission at Washington, D. C., for Form 304, which contains full information.

GOVERNORS of American States have only strictly limited authority. The 'House of Governors,' formed as a result of the famous conference at the White House, therefore can only serve as a means of promoting co-operation. It cannot legislate. Since, however, in order to win election as Governor, a man must usually be an expert in estimating and leading public opinion, this body is of great potential power. In China an equally significant movement is now under way, the Regent having recently called the Viceroys of the various provinces together in general conference. A Viceroy in China has much more authority than does an American Governor, and events may therefore be expected to proceed with greater rapidity. The calling of the conference at Peking is indicative of changing conditions and affords another analogy to American methods.

AMONG pleasant features of the week at Los Angeles were the field trips. Members of the Mining and Metallurgical Society and guests spent Saturday and Sunday inspecting the work in progress along the Los Angeles aqueduct under guidance of J. B. Lippincott and other engineers engaged in building that great work. Saturday night an elaborate dinner was enjoyed at Mojave, followed by an account of the aqueduct by Mr. Lippincott, and of tunneling methods at Loetschberg by C. H. Richards. Monday, Tuesday, and Wednesday a large party of visitors inspected the Kern River oilfields. Throughout the week the members of the Congress and delegates were shown many courtesies by the Sierra Madre Club, the Chamber of Mines, and the citizens of Los Angeles, and all will remember the meeting as one of the most pleasant in the history of the Congress.

MINING MEN should begin now to plan for the Panama-Pacific Exposition which is to held in San Francisco in 1915. The Western States in particular should be prepared to make notable exhibits of their mineral resources, and in order to do so special efforts must be made. The systematic collections preserved in Museums will doubtless be available and will be of great service, but exposi-

tions eall for another and different sort of material. The ordinary visitor is more impressed by striking and showy specimens than by those which require special knowledge for their appreciation. Even technical men are apt to be attracted to exhibits by the unusual features of the collection. Most 'specimen ores' find their way promptly to the smelter, as is right and proper, but arrangements should be made to collect in the next five years the best that are found and preserve them at least till after the exposition. It is important that mining should be well represented, and in this particular, time and forethought is quite as important as is money.

COAL MINE accidents are usually most abundant in the winter months, due partly to natural causes, such as the climatic conditions, and partly to artificial conditions contingent on the greater activity of coal mining from October to April. This year the opening of the danger season was signalized by a serious explosion at Palu, near Monterey, Mexico. It is reported that 72 miners lost their lives. In the United States and Canada steps have recently been taken to minimize the dangers of mining. In Mexico coal mining has been a minor industry, and attention has not yet been concentrated on the problem. The deplorable results of the accident at Palu will doubtless lead to the adoption of preventive measures.

ELY CENTRAL continues to be a storm centre and the trouble has entangled some who deserve better of fate. For B. H. Scheftels & Company there is scant sympathy. Their methods were of the sort that bring mining into disrepute. While their literature would not deceive any trained mining engineer, many of the statements were grossly deceptive to the class of people that they reached. The attack made on the firm by our New York contemportry, *The Engineering and Mining Journal*, attracted general attention, and the theatrical raid on the offices of the firm in New York and other cities September 29 will probably stop what the Department of Justice at Washington considers grossly illegal operations. This is a welcome effort to clean up the New York Curb and we hope it may do good. One of the stocks boomed by the firm was Ely Central. In the last year this ground has been systematically explored under direction of the Constant-Herzig Company as consulting engineers to the Ely Central Copper Company. The mine has been studied by such experts as Mr. Walter Harvey Weed and Mr. Charles S. Herzig. Recent development has borne out their theory of the geological structure of the ground and strongly confirmed the expectation of finding a large body of ore. The property itself seems about to prove valuable. A good mine, it is true, is not always represented by a good stock, and the duties of consulting engineers are hard to define. A heavy responsibility attaches none the less to a firm that continues to furnish reports, however accurate and well justified, to those who are guilty of misrepresentation. Mr. Weed is no longer connected with the property, having retired from the C. L. Constant Company some months since. Mr. Herzig has the misfortune to be related to the principal partner in B. H. Scheftels & Company. He has built up an excellent reputation by years of careful and able work. His many friends regret greatly to see him entangled in any way in the scandal, as a result of a natural though probably unwise effort to assist a relative.

METALLURGISTS will find much of interest in the program of the eighteenth general meeting of the American Electrochemical Society to be held in Chicago next week. Sessions will be held for the reading and discussion of papers in the forenoons of October 13, 14, and 15; the afternoons will be devoted to excursions, and Friday evening is to be given over to a subscription dinner at the Congress Hotel. There is much in and about Chicago to interest electrochemists and metallurgists, and many plants will be open to the visitors of the week. Among the papers to be read will be one on 'The Electric Furnace and Its Application,' by Marcus Ruthenburg; another, on 'The Application of Electrostatic Separation to Ore Dressing,' by F. S. MacGregor. Other papers of less direct interest to metallurgists are on the program and it is evident that this junior among engineering societies is attracting the support of men in a wide range of industries.

Southern Pacific Oil Lands

The oil lands controlled by the Southern Pacific railroad in California have come in for renewed interest in view of the discussion at the Los Angeles meeting of the American Mining Congress. These lands are disposed in checker-board fashion through some of the most productive oilfields and are immensely valuable. At the time they were given to the railroad company they were supposed to be agricultural and, indeed, were not thought to have much if any value. In the act of Congress granting them there was the usual provision that only agricultural lands should be selected and that if any of the allotted sections proved to be of value for minerals other than coal and iron, they should be exchanged for non-mineral lands. The whole transaction was of the sort common at that time and the policy of giving land to encourage building railroads was then well established in public favor. In a number of cases elsewhere in the West and under the terms of similar grants it is now known that there was much fraud in the classification of the lands selected and that as a matter of fact much mineral land was patented to the railroads. The courts have refused to review the findings of the Land Office as to questions of fact and have held that a classification made by authorized Government agents is binding against the Government itself, except where there is actual fraud. In such cases questions of title must be raised by the Government within six years of passage of title or the patents become valid. In the case of the Southern Pacific and the oil lands in question, no sufficient evidence of fraud has been shown; indeed it is well known that the company made repeated efforts to sell as agricultural land many pieces on which oil has since been discovered.

Aside from that, the patents having been issued in 1894, the period for action under ordinary rules has passed. It happens, however, that there is in this case a modifying circumstance. The patents as issued are said to have contained a clause retaining to the Government all mineral lands. This condition in the patents has not been tested in the courts, and just how important it may prove to be, cannot be predicated in advance of litigation. In view of the fact that the intention of Congress was not to give mineral lands, and that the officials of the company in accepting them evidently believed that only agricultural lands were received, there would seem to be an equitable reason for bringing the matter before the courts and restoring to the United States the title to the mineral in the ground if possible. The railroad would retain all that it bargained for, no more and no less. It is not the part of good government to unsettle titles unnecessarily, but if the title conveyed be in fact, as it seems, a restricted one, there is no injustice in enforcing its terms. It is properly a matter for the courts and we have no desire to argue the case in advance. In the interest of the railroad company, which may wish to sell the lands, as well as in the interest of the public, the matter should be tested promptly.

Dynamiters at Los Angeles

Destruction of the building occupied by the *Los Angeles Times* seems now certainly to have been the result of a deliberate plot. At first there was reason for supposing the explosion and fire to have been caused by a leaky gas pipe; but accumulating evidence, particularly the discovery of infernal machines at the residences of the proprietor and elsewhere, timed for simultaneous explosion, makes it clear that the loss of twenty-one lives and a valuable property must be charged to conspiracy. With one voice the public is demanding that the perpetrators of the outrage be hunted down and made to pay the penalty of their crime. Rewards aggregating $100,000 have been, or are about to be, offered. The deed deserves, as it has, the condemnation of every right-thinking man. There can be no acceptable excuse, and no condonation of such a crime if society is to be perpetuated. Wholesale assassination is the worst of crimes against civilization. The aroused public interest and the rewards offered are likely to lead to detection of the conspirators; already substantial progress has been made in that the circumstances under which the dynamite was purchased and shipped from a point on San Francisco bay have been made known. In this connection a word of caution is in season. The names given by the men who purchased the explosive at Giant were those of Messrs. James L. Bryson, William Morris, and Robert Leonard. These are the names of the owners of the Rawhide mine near Towle in Placer county, men of good reputation. Their names were chosen by the dynamiters in order to deceive the employees of the powder company and lend plausibility to the purchase; a plan that worked admirably. Great rewards are dangerous as well as helpful. Men who resort to dynamiting as a means of revenge, are crafty and scarcely regard perjury as a crime. Circumstantial evidence has involved many an innocent man in difficulties and in times when public opinion is, as now, properly aroused by a great crime, enormous rewards have a tendency to defeat as well as to secure justice. We sincerely trust that no mistake may be made. In view of the long fight made by General H. G. Otis and his newspaper against organized labor, and the bitterly contested strike that has for months past been in progress at Los Angeles, it is not unnatural to impute the dynamiting to union labor men. However natural this may be, it by no means follows that the imputation is just. It is quite true, and no one knows it better than do mine owners, that dynamite has been used in the West all too frequently as an argument in labor troubles. We are frank in our statement of belief that in instances this has been done with the knowledge and approval of officers of certain unions. We are glad to believe that such things will be exceedingly infrequent, if indeed they occur at all, in the future, and we unhesitatingly state that we do not believe that the real leaders of organized labor tolerate any such methods. Even if we could suppose them to be so inhuman as to approve of killing in mass, results have shown that the outrage reacts to defeat its purpose. The strike now in progress at Los Angeles is everywhere recognized as of the largest importance to the whole labor movement on the Pacific Coast. The men have had the support of their fellows in San Francisco and elsewhere as well as the help and guidance of the wisest and ablest of the labor leaders. It is not thinkable that they would be so foolish or so base as to sanction such an outrage. On the other hand, the fight that the *Los Angeles Times* has been making on union labor is the kind that embitters. General Otis gives no quarter. He has roused the passions of many an obscure man who is now out of work and who blames his suffering on the paper and its owner rather than on himself. Such men brood over their injuries and it would need but a few to form a band quite capable of carrying out the evident conspiracy. It will be recalled that the attempted assassination of Mr. W. J. Gaynor, Mayor of New York, was the single-handed attempt of an obscure individual, and that when McKinley was killed it proved, to the surprise of many, that there was no widespread conspiracy. We believe, and we hope it may prove, that the same is true in this case. In the meantime, as in every recent assassination in America, there is a lesson, particularly to the gentlemen of the press; bitter denunciation engenders bitterness and delays rather than forwards the mutual understanding that must precede good working conditions. Whether an editor be for or against unionism, or indeed any other movement, he will best serve his cause by moderate and informed discussion rather than by violent diatribes. Every effort should be made to capture and punish all concerned in this outrage, but let us at the same time take thought to improve conditions so that we do not multiply rather than decrease the number of dynamiters.

American Mining Congress

(Editorial Correspondence)

The thirteenth annual session of the American Mining Congress at Los Angeles, September 26 to October 1 inclusive, was notable for the position and standing of the men attending rather than for the numbers present. Not that the attendance was small; on the contrary, it was larger than at many preceding sessions, some 1200 members and delegates having registered. As is usual, there were in addition many unregistered visitors. At several sessions the Mason Opera House, in which the meeting was held, was crowded; but generally the number in actual attendance in the hall was only 200 to 300. This, however, by no means measured the interest in the meeting. It was apparent that the attendance differed materially from day to day, and evidently each visitor interspersed sight seeing with attendanee on the sessions of particular interest to him. There are many attractive things to see in and about Los Angeles, and delegates cannot well be blamed for wandering.

The opening session Monday was devoted to the usual addresses of weleome and responses on behalf of the Congress and the States. Among the speakers were Alden Anderson, George Alexander, Joseph Scott, E. A. Montgomery, F. G. Tyrrell, R. W. Brock, L. W. Powell, E. H. Benjamin, D. W. Brunton, David Ross, J. W. Malcolmson, J. W. Abbott, F. J. H. Merrill, George W. E. Dorsey, John Dern, and others. In the evening E. R. Buckley delivered the presidential address, printed on another page of this issue. Mr. Buckley gave a systematie review of the work of the Congress, and his presentation of the problems yet to be met produced a deep impression. He was followed by Gifford Pinchot, whose brief address attraeted more attention than any other delivered in the course of the week. It has already been brieffy noted in the *Mining and Scientific Press*. While it produced a markedly favorable impression at the time, the aetual resolutions adopted by the Congress were determined by anti-Conservationists, who remained patiently 'on the job' through the week. Evidently he who speaks and runs away may need to speak another day.

Tuesday was devoted mainly to discussion of the problems of the oil men, who attended in force. It was soon evident that there was much difference of opinion as to what should be the attitude of the Government toward the petroleum-bearing public lands. S. C. Graham, who made the chief defense of the conservation policy of withdrawing the lands from entry and opening them only under some entirely new system, was clearly in the minority. He told some plain truths which were not altogether palatable, but in general the debate, while warm, was not acrimonious. Messrs. S. C. Smith and T. A. O'Donnell made the principal pleas for those who would retain the present laws with as little modification as possible. One eloquent speaker said, apropos of the activity of Eastern men in conservation matters, "We don't know what we want, but we don't want you to tell us." It must be said that the oil men are entitled to much sympathy. It was supposed when the present land withdrawal law was enacted that the interests of those who in good faith had located lands prior to withdrawal and proceeded steadily to develop them, were amply protected. The combination, however, of the withdrawal and a recent ruling to the effect that discovery must preeede location, leaves them wholly unprotected. It is clear that equity demands some form of relief, and it is not surprising that oil men generally resent any movement toward extension of Federal supervision of the industry. While oil matters occupied the attention of the Congress most of the day there were also on the program addresses by J. W. Abbott, on 'Railroads and Mining Development'; by Tracy C. Becker, on 'Railroad Rates on Ore Shipments'; by E. W. Parker, on 'Conservation as It Affeets Coal Lands'; and by George S. Rice, on 'Investigation of Mine Accidents.' Some of these papers are printed in this issue and others will appear later. Tuesday evening there was a reception given by the Chamber of Commeree, at which there were numerous short addresses. Wednesday, Thursday, Friday, and Saturday forenoon were devoted to papers and discussions; since reports from the Resolutions Committee had right of way, many interesting and valuable papers were read by title only. Among the most important features were the reports of the committees on 'Revision of Mineral Land Laws,' by Will L. Clark; that on 'Uniformity of State Laws and Prevention of Mine Accidents,' by J. Parke Channing; and 'Alaskan Mining Laws,' prepared by Henry R. Harriman, but read by Mr. Buckley. Wednesday evening J. A. Holmes delivered an address on 'The Bureau of Mines and Its Work,' presented on another page. This was followed by the brief addresses of S. B. Christy, David T. Day, and others. Thursday was given over mainly to discussion of the report of the Resolutions Committee on all resolutions relating to conservation. It was soon evident that the 'stand pat' element was in the majority. The resolutions recommended by the committee praised conservation in general terms, and then pronounced for State rather than Federal control and against any form of leasing. The report of the sub-committee was presented by C. F. Potter, of Denver, an attorney said to be employed by one of the large power companies. In the ensuing discussion there was a large amount of eloquence and considerable misinformation. For example, the gentleman presenting the report referred at length to early experience of the Federal Government with leasing in connection with the lead-bearing lands in the Mississippi Valley and to some of the complications that led to its abandonment. He then stated that the leasing system being abandoned and titles made secure, gold was discovered the next year in California. The fact was that when gold was discovered in California, and up to 1866, there was no legal way to get any title to public mineral land, and all miners were trespassers. Instead of security, there was the utmost insecurity of title, and yet prospecting was

fairly active. One speaker announced that what the miners wanted was 'the good old law under which we can make money and can lose money.' Altogether there was a surprising ignorance of the actual working of the lease system which is so widely applied everywhere except in the Western American States. It is evident that if the advocates of a change are to win the day they will have to wage a vigorous campaign of education. At present the miners remember only their unfortunate mishaps with the Land Office and other Bureaus of the Government and they are jealous of any extension of Bureau control. Other resolutions adopted by the Congress congratulated Mr. Taft upon his appointment of J. A. Holmes to the position of Director of the Bureau of Mines, and pledged the support of the Congress to the new Bureau and to the Geological Survey. The action of the Bureau of Mines in making the prevention of mine accidents its first concern was endorsed; the creation of a laboratory to study the chemical and physical problems underlying modern metallurgy was advocated; the importance of keeping the Bureau and its officers out of all private work, the need of marking desert trails, the vital necessity of unrestricted prospecting on the public lands, and the advisability of the Department of Justice re-investigating title to all mineral lands passed to railroads in land grants, were also urged.

Thursday evening at the business session of the Congress, Messrs. John Dern, E. R. Buckley, E. A. Montgomery, L. W. Powell, and C. A. Barlow were elected directors, and plans for improving the financial position of the organization were discussed. At a subsequent meeting of the Board of Directors, John Dern was elected president, and D. W. Brunton, S. A. Taylor, and E. A. Montgomery vice presidents. J. F. Callbreath, Jr., was re-elected secretary. Mr. Callbreath, unfortunately, was not able to attend the sessions of the Congress, being confined to his room by ill health. We are glad to report that he is recovering rapidly. In his absence Sidney Norman officiated to the satisfaction of all. Monday evening, following the session, the Sierra Madre Club kept open house. Wednesday noon, at the Hotel Alexandria, the Directors of the Chamber of Mines gave an elaborate luncheon to the officers of the Congress and invited guests. Thursday evening the members of the Mining and Metallurgical Society of America present in the city, with a few guests, had a dinner and meeting at the Sierra Madre Club. An interesting feature of the occasion was the presence of the presidents of the three American societies devoted to mining, D. W. Brunton of the American Institute of Mining Engineers, E. R. Buckley of the American Mining Congress, and J. Parke Channing of the Mining and Metallurgical Society itself. Friday evening the Sierra Madre Club gave a smoker and vaudeville on the roof of the Hamburger building, Saturday there was a dinner and dance at the Virginia Hotel, at Long Beach, and Sunday an excursion to Catalina island. The ladies in attendance were entertained at tea Wednesday afternoon at Hotel Alexandria and given an automobile ride around the city Thursday.

Work of the Bureau of Mines

*The Bureau of Mines was created by Congress as the result of a demand coming not only from the mining industry, but also from the general public in different parts of the country. This movement for appropriate recognition and aid for the mining industry from the National Government has been under way for many years. Among its early and most active and successful supporters has been the American Mining Congress. It is, therefore, eminently appropriate that at the first session of this Congress following the creation of the new Bureau of Mines, something should be said of its policy and purpose.

The chief purpose of the Bureau of Mines is the development of greater safety and efficiency in mining. It may be expressed in another way as 'lessening the loss of life and the waste of resources' in connection with the operations of the American mining industry. Or, as expressed in a yet different way, its chief purpose is the 'conservation of the lives of the miners and the mineral resources of the country.' If, in view of the fact that the Bureau has no means of enforcing and carrying out its recommendations, the question is raised as to how it can aid in the accomplishment of these purposes, it may be said in answer that the Bureau neither needs nor desires any authority, except that based upon an enlightened public opinion. The Bureau will endeavor to aid in carrying out these purposes by conducting investigations and inquiries into the best mining and treatment practices to be found in different mining countries, and into the fundamental chemical and physical problems that serve as a basis for more efficient metallurgical operations. It will thus endeavor to indicate how all branches of the industry may become both safer and less wasteful; but the Bureau will leave to other agencies the enforcement of new requirements, or even the adoption of its recommendations. It will, to quote the language of the statute creating the Bureau, "make diligent investigation of the methods of mining, especially in relation to the safety of miners, and the appliances best adapted to prevent accidents, the possible improvement of conditions under which mining operations are carried on, the treatment of ores and other mineral substances, the use of explosives and electricity, the prevention of accidents, and other inquiries and technologic investigations pertinent to said industries, and from time to time make such public reports of the work, investigations, and information as the Secretary of said Department may direct, with the recommendations of such Bureau." It will publish the results of these investigations and inquiries in such form as to make them easily interpreted in daily mining practice in the United States.

The new Bureau will do everything it can do to encourage each State in the investigation of its own

*Address by J. A. Holmes, Director of the Bureau, at the session of the American Mining Congress, Los Angeles, California, September 28, 1910.

local mining problems, and in the proper inspection and supervision of the mines operating within its borders. It will do everything possible to help maintain and increase the influence and effectiveness of the State Mine Inspector. It will endeavor to cooperate with, but not to belittle or supplant, the work of the State. Similarly, it will do everything within its power to encourage private mining corporations to investigate their own local problems, and to properly inspect their own mining operations, with the view of lessening the loss of life and waste of resources. It will itself take up inquiries and investigations in which the National Government as such is a party at interest, and to those other problems in relation to the mining and treatment of our mineral resources that are general in their application, or national in their importance. The Bureau will in this way endeavor to minimize the responsibility of the Federal Government; and to minimize the contribution which the Federal Treasury may be called upon to make in behalf of a proper development of the mining industries. In the wise development of our two great foundation industries, agriculture, and mining, which are alike essential to the present and future welfare of the Nation, the Federal Government, the State, and the private individual or corporation each has its responsibility and its duty, which responsibility and duty no one of them should shirk. The welfare of each is essential, and each should co-operate with the other for the accomplishment of the important purpose in view—the safest and most efficient use of our resources, considered in its relations to both the individual and the Nation, both the present and the future.

The work of the new Bureau should not diminish the work of the private mining engineer, but, on the other hand, should increase his work by pointing out to mine owners additional problems which he should be called upon to solve at the cost of the parties most interested. Such has been the result of the preliminary work conducted by the Technologic Branch of the Geological Survey during the past few years, and a similar result should follow the work of the Bureau of Mines. In all these relations the aim of the new Bureau will be that of helpful co-operation, and not of interference or suppression.

Every one responsible for the establishment of the Bureau of Mines realizes the fact that its first duty is to aid in lessening the loss of life in mining. Those associated with the work of the Bureau realize that the mine owners of this country are in full sympathy with this purpose, and that they stand ready to put into practice, as far as conditions will permit, every practicable recommendation and suggestion that the Bureau may have to make. On the other hand, the people of this country are beginning to realize that many of the methods practised and appliances used in other countries, where profits of mining, and especially of coal mining, are far greater than in the United States, can not easily be introduced into the United States, because their cost would exceed the profits of the industry here; as no industry can operate on a basis of financial loss. Nevertheless, progress is being made, as shown by the fact that the loss of life in the American mines has decreased more than 25% during the past two years. If the miners, mine owners, and mine inspectors of the country will more earnestly co-operate with each other in a determined effort, the result will be a still further lessening in this loss of life during the current and succeeding years. The appeal of the new Bureau is therefore to every man connected with the mining industry in this country, to the mine worker, the inspector, and the mine owner alike, that he do everything that can in reason be done to safeguard the lives of the men who labor underground; to see that the disasters at Monongah, Darr, Marianna, and Cherry shall have no counterpart during the winter of 1910; and that the daily toll in the lives of miners from other causes, less impressive, but in the aggregate more destructive than these awful disasters, shall steadily diminish. Of all the great mining countries, the United States is pointed out as the most wasteful of both life and resources. It was with a view to remedying this situation that a National Bureau of Mines was created.

In the demand for the creation of this Bureau, the mine owners and mine workers alike have joined. Let no one of these suppose for one moment that with the establishment of the Bureau his work has ended; for in reality it has only just begun. It is only under the good advice of those most familiar with all branches of mining that wise leadership by the new Bureau can be properly developed; and the Director of the Bureau will welcome such advice. It is only through the hearty determined co-operation of the mine owners and the mine workers that substantial progress toward better conditions can be made.

In the competitive branches of the mining industry, such as coal mining, the lawmaker also must contribute by helping to improve the economic conditions which now hinder wise practice and development. All these agencies must co-operate if the mining industry as a whole is to reach that higher standard of safety and efficiency which should characterize this American industry, and to which we look forward with full hope of accomplishment. There are many difficulties in the way, and the path will not in all cases be plainly marked. There will be differences of opinion, both as to what should be done, and as to the mode of proceedure. But the Director of the new Bureau wishes the members of the American Mining Congress, and mining men throughout the country, to know that their suggestions and advice will be welcome always, even if it cannot always be followed. He realizes that this Bureau is not his, but yours, and his highest aim will be to render a disinterested loyal service to the mining and metallurgical industry in all its branches, in all parts of this country.

Small aquatic and insect life flourish around the borders of the Sargasso Sea. There are numberless varieties of fish, molluscs, shrimps, crabs, and waterfleas. Almost invariably this life takes on the protective color of the masses of yellow weeds in which it lives.

Presidential Address

By E. R. Buckley

*It is gratifying to be able to report a most successful year in the history of this organization. Our financial condition has improved and our membership has increased. Our legislative campaign has been a success and the committees have been especially active in conducting the investigations committed to their charge. The American Mining Congress has been accorded scant recognition in some sections of the country during the years passed, partly on account of its aggressive policies, partly on account of manifest indifference, and partly on account of the men who represented those policies. Today the attitude of indifference is passing, and we include among our members many of the foremost mine operators and mining engineers of the country, all of whom are sharing in the work which this organization is carrying on.

The work of this Congress is an association of men interested in mining, maintained for the purpose of encouraging mining in all its various phases and to promote a spirit of co-operation between the mining industry and agriculture, manufacturing and transportation, to the end that the development of these industries may be mutually helpful and that each may receive from the other and from the Federal and State governments its just proportion of encouragement through co-operation.

This Congress has no systematic means of securing funds, except through the fees and annual dues of members. These alone will about sustain the permanent headquarters, paying the salary of the secretary and the clerical force. The fund obtained in this way has never been adequate to carry on legislative campaigns and pay the expenses contingent upon the annual meeting. The campaign for the Bureau of Mines last winter required the maintenance of an office in Washington for six months, and the almost exclusive time of the secretary and a clerk. This campaign was made possible only through the efforts of the Sierra Madre Club of Los Angeles, which secured voluntary contributions from mining men of the Southwest sufficient to meet these expenses. It ought now to be possible for the organization to carry on such legislative work as may be necessary from the permanent headquarters. This will afford the secretary an opportunity to devote his time and attention chiefly to the work of strengthening the membership and securing of voluntary contributions to provide for any liabilities which may be incurred in excess of the receipts from annual dues and membership fees.

Several years ago the Mining Congress provided for the establishment of branches in the mining centres of the country. Several branches have already been organized and others are in prospect. There appears to be no reason why many of the local mining organizations should not affiliate with the Mining Congress, thereby serving the industry at large and securing for themselves the close and intimate co-operation of the national organization. Undoubtedly there are many questions of a local character which cannot be dealt with through the national organization, but that organization might render important service to the local branches in solving these very problems. The organization of local branches cannot be easily effected without having a representative of the national organization on the ground. For this reason it is thought that in conjunction with the work for members during the coming year the secretary might devote a portion of his time most profitably to the organization of branches.

At the Portland convention, after a strenuous contest, permanent headquarters were established in Denver. This action was taken with the understanding that the State of Colorado and the city of Denver should provide amply for the housing and care of such headquarters as might be required to carry on the work of the organization. The permanent headquarters of this association are a credit to any city, to any State, and I believe that any city or State that has been neglectful of its obligation should be reminded of the fact that there are other States and other cities which will not only be willing but glad to assume any measure of responsibility necessary to maintain this organization in their midst.

After 13 years of agitation for recognition by the Federal government, 10 years of which was spent in a hopeless struggle for a Department of Mines, with its head a member of the President's cabinet, there has been created a Bureau of Mines, for the maintenance of which $502,200 has been appropriated. I can only believe that it was through some misunderstanding on the part of our representatives in Congress that the appropriation for the investigation of our structural materials was made to the Bureau of Standards rather than to the Bureau of Mines. These investigations clearly belong to the Bureau of Mines, and there should be little difficulty in having Congress direct any subsequent appropriations into the proper channels. The Bureau of Mines has been created on broad principles which will admit of carrying on any technological investigations which may be construed as being pertinent to the mining industry. In importance it stands equal to the long established Geological Survey, which has rendered much important service to the mining industry in the field of exploration.

The mining industry is now represented by two Federal Bureaus, of equal importance; one of which is concerned with those activities which are exploratory in nature, and the other of which is concerned with such activities as may be termed operative, or technological. Because this association has been active in the creation of the Bureau of Mines is no reason that it should forget its obligations to or withhold its support from the Geological Survey. Neither should we in any way permit the personnel of the Bureaus to influence our activities in behalf of either. From diligent inquiry I find that there are many fundamental problems connected with the

*Abstract of address by E. R. Buckley, president of the American Mining Congress, delivered September 26.

treatment of ores in the Western mining camps awaiting such investigations as appear pertinent to the Bureau of Mines. In my own State, for example, I am confident that of all the zinc mined, not to exceed thirty per cent has ever reached the consumer. I commend to you for your consideration the desirability of urging upon Congress the making of appropriations to the Bureau of Mines for carrying on investigations in the metal mining districts, where losses of this nature are evident.

I have yet to hear any well founded argument against the establishment of experimental stations by the Federal government to assist in solving the more difficult problems of ore concentration.

In connection with a revision of our mineral land laws there appears to be much difference of opinion as to what is most desirable. It is evident that there is at present too much litigation in perfecting and retaining titles to mineral lands and this appears to be attributable to the nature of our Federal and State laws. There is dissatisfaction in the classification of the lands of the public domain, especially as pertains to the rulings of the Forestry Service. In some of the larger mining camps, much land is tied up through ownership by extinct corporations, through questionable tax titles, through ownership by widely scattered co-tenants, and in estates which have not been administered upon. In the case of Leadville, for example, the ores are widely distributed. There are perhaps 5000 mining claims in this camp and yet only a small portion of these are being developed, and in a great many cases it would probably be impossible to find all of the owners and when found it would not be uncommon to learn that they would be unwilling to co-operate with each other to mine or prospect the property. In a great many cases the owners await development of the property, until adjacent properties have disclosed something of value believing it to be to their ultimate interest to do so. As a result more than one-half of the desirable mining property in this district is idle, and no one can develop it. I call your attention to the report of the committee on the Revision of Mineral Land Laws. It is evident that this organization should seriously consider the recommendation of a general revision.

There is also the question of establishing assay laboratories under the Bureau of Mines for the making of free assays in the case of undeveloped properties. This as well as the proposition for the establishment of experimental stations has been objected to by mining engineers and professional assayers on the ground that it would be an infringement upon the work of a well established profession.

The mining industry has suffered for years from the pseudo-professional man who lends himself to the support of fake mining propositions. The public at large has little acquaintance with the standing of the various individuals who make reports upon mining properties. There should be some way of publicly branding these fakers. How best to bring about a change in this condition is a matter worthy of your consideration. As a result of the activities of this organization, several of the States have enacted laws to punish the man who handles mining stocks with the purpose of defrauding the public. While it might be possible to estimate the amount of money going into mining propositions it is not easy to determine how much is going into actual mining. Overcapitalization of many otherwise meritorious mining propositions has long been practised, and I believe that another method of restoring confidence in the mining business would be to urge upon the several States the enactment of laws which would prevent this imposition from being practised upon the investing public.

Under our present system of judicial procedure the burden of proving negligence, upon which the recovery of damages in the case of accident, depends, rests upon the plaintiff. The difficulties surrounding the producing of this evidence and the consequent practical impossibility of securing reasonable and just compensation for injury through the strictest employers' liabilities laws, is evident to any one who has come in contact with such proceedings. This question has been under consideration for a year. Let us, as a representative body of mining men, not only endeavor to secure such legislation as may lessen the dangers attendant upon mining but also to give our influence to the perfecting of plans whereby the laborer and his family may be adequately compensated, in case of injury or death.

While we are giving attention to safety in mining we should not forget the question of health. The breathing of dust from drilling machines and from illuminants and also from deteriorated air is harmful to those who spend their nights or days beneath the surface. It is possible that something might be done to better the conditions in the way of sanitation and ventilation.

Uniformity of State laws governing mine inspection will be the subject of a report by one of the standing committees. The laws regulating mining are as many and as varied as there are mining States. Many of the provisions of these laws might be made uniform throughout the country, in spite of varying local conditions.

This organization should express its continued interest in mining education. The public, let alone those engaged in the business of mining, know too little about even the elements of mining. The establishment and maintenance of mining schools in many of our States has been a struggle against the widespread demand for agricultural and general engineering education, which of late years has swept the country. We maintain that mining is as important to the industrial development of the country as agriculture, and there is no reason why our Government should not provide as liberally for the one as for the other.

One who has given attention to the price of mining stocks as quoted on the various exchanges of the country cannot help but be struck with their constant fluctuation, regardless of the actual changes in the condition of the properties. The price of mining stocks does not depend altogether upon the earning power of the property. The fluctuations are the

result of buying and selling, chiefly on margins, which is gambling. The business conditions of the country would be vastly improved were it possible to eliminate this speculative element from our industrial activities. There is now a movement on foot, led by the Mining and Metallurgical Society of America, to provide the New York Curb Exchange with authentic reports concerning the actual condition of mining properties listed on the Exchange.

The reports of many of the mining companies are very meagre as to earnings and reserves, on account of which stockholders are not acquainted with the condition of the properties in which they have invested.

During the past few years much has been said and written upon the subject of conservation of our natural resources. It is an old subject, almost as old as civilization. It is a question of extravaganee; a question of wasteful and luxurious living. We have been and are today living in a land of plenty, and perhaps too little thought has been given to the careful exploitation of our natural resources. The great corporations of the country are being looked upon by the public as the destructive agents of the present generation. Strange as it may seem to some, in the mining industry, at least, they are the least wasteful of the natural resources, which they are engaged in exploiting. There appears to have been some confusion of the question of conservation with that of ownership of the public domain. They undoubtedly have some relation to each other, but in their fundamental natures they are distinct problems. Dr. T. C. Chamberlin, of the University of Chicago, has recently made the point, and rightly I believe, that "Conservation of our natural resources centres in the scientific and technical" while "the right of ownership and the most desirable distribution of ownership centre in the political and sociological." This means that whenever it shall have been determined whether the lands of the public domain shall be owned or leased by the individual, company, or corporation, we will still be confronted with the question of conservation. As far as the conservation of our mineral resources is concerned, it must be conceded that such ownership or distribution of ownership as will result in the least waste, is theoretically the most desirable. This organization is vitally interested in conservation, as well as in the question of the disposition of the public domain, in so far as it affects the mining industry. I do not wish it to be understood that this body has less to do with the one than with the other, but this I do wish to emphasize, that in dealing with these questions, by resolution or otherwise, consider them apart from each other as far as possible.

Four things appear to be perfectly clear in a consideration of the conservation problem: First, as mining men we cannot afford to have the government enact legislation which will make the occupation of mining more hazardous; second, that nothing shall be done that will retard the development of manufacturing industries that depend upon the products of the mines for their business; third, that everything possible be done to increase the percentage of metals that can be recovered from ore and from deposits of coal, oil, and gas; fourth, to bring about as quickly as possible the use of substitutes for the present sources of power and for the metals which are supposed to be limited in quantity. The waste in coal mining is said to approximate 50%. This waste, however, cannot be decreased beyond a point where mining becomes profitable. Under the present conditions of the industry there appear to be five ways in which this waste may be lessened, namely, by improved methods of mining, by decreasing the profits, by increasing the price of coal to the consumer, by reducing the price of labor, and by securing markets for the poorer grades of coal. In the direction of improved methods of mining and marketing the poorer grades of coal, the Bureau of Mines should be of assistance. In some of the other directions there may be an opportunity to decrease waste, but these are matters which require investigation.

In searching for ways and means of eliminating waste in mining; in the investigation of ways and means of securing greater efficiency, more heat and power, from the mineral fuels; in the investigation of new sources of heat and energy; and in making available other known sources there is a vast and important field for governmental activity. It has been estimated that the water power of our streams is capable of producing about 30,000,000 hp.; more than is necessary to turn every wheel of industry in the country. Some of this power is not at present available and probably will not be for generations to come.

The man who is engaged in mining is also interested in conservation as it affects our forestry policy. I think that every one is interested in the conservation of our forests, that is, the protection of our timber supply against the waste and destruction which has marked the advent of the lumberman in his march across the continent. On the other hand the rulings of the Forestry Bureau have, in some instances, caused unnecessary hardships to the men engaged in mining who have sought to secure timber for their legitimate operations. This may not be due so much to the rulings of the Forestry Bureau as to the placing in the hands of incompetent and irresponsible forest rangers the authority to interpret and enforce these regulations. There will be no diminution in the amount of timber cut and manufactured into lumber until the public is supplied with materials for building which will be equally satisfactory and as cheap as lumber, or until the demand for structural materials shall lessen. No one anticipates a time when the demand for building materials will lessen, for that means business stagnation and industrial decadence. However, we all look forward to the time when brick, tile, terracotta, and concrete can be used in building constructions at a cost which will not exceed that now paid for lumber.

Among our metal resources iron and steel, from an industrial standpoint, may be considered the most important. The rapidity with which known iron reserves are being exploited may justify the apprehension that within a century or two this material will be insufficient to supply the demands of industry.

There are, however, vast quantities of low-grade iron ore which have been ignored in most estimates of iron ore reserves. It is believed that these ores will become available through improved processes of concentration or smelting by the time the richer deposits fail to supply the demands of the iron and steel industry. We know that aluminum, which is now produced in limited quantities, can be used in many places as a substitute for steel and iron. There are unlimited quantities of aluminum combined with silica in the form which we know as clay. In quantity it is as nearly inexhaustible as any material we have. I feel confident that some day we will know how to separate, commercially, the aluminum from the silica, thereby providing a metal substitute for iron and steel. In the present stage of our industrial development copper is an extremely important factor. There is every evidence that this material occurs in sufficient abundance to meet all of our industrial demands for many decades to come. The demand for this material will decrease with the development of the wireless telegraph, the wireless telephone, and the storage battery cars. With the development of these new methods of transmission I anticipate that the time will come when the demand for copper will decrease rather than increase. Whether a time will come when substitutes will be found for lead and zinc it is not so easy to predict. These metals are used for a multitude of purposes, many of which could be eliminated without seriously affecting our industrial progress. Although I am opposed to any policy which removes from the public the possibility for developing any of our mineral or allied resources, I would not have you think that I am opposed to conservation or that I wish in any degree to retard the movement against the extravagance of our people. I deplore the fact that we place so small a value upon the lives of our citizens working in our mines; I deplore the waste of our mineral resources; and I believe that the Federal and State governments should do everything in their power to protect the lives of their citizens and compel individuals and corporations while using our resources not to abuse them.

I am not opposed to the organization of our industrial activities through the formation of well capitalized corporations. Any criticism that might be offered would be directed against the methods by which the business of some of them is conducted and the utter lack of respect which some of them have for the less powerful competitive organizations and for the public at large.

I believe that our governmental activities should be directed to the control and regulation of our great industrial organizations, while at the same time generous support should be given by the Federal and State governments to technical and scientific investigations. Through the proper encouragement of research I believe that the ingenuity of our people will meet the conservation problem and that the expansion of commerce and manufacturing will go on, unless luxurious living, too often the accompaniment of great wealth, destroys this nation, as it has the great civilizations of the past.

The question of the ownership of the public domain should be considered apart from that of conservation. In doing this it should be remembered that ownership, which may be otherwise desirable, may be undesirable from the standpoint of conservation and vice versa. In all discussions which may come before you bearing on this question, keep clearly before you the fact that the question of ownership is political and sociological while conservation is technical and scientific.

It is not my purpose to discuss this problem, but when you consider it in the sessions of this Congress or in committee, remember that one of the greatest incentives to exploration, to prospecting, in this country has been the right of possession after discovery. Remember that the possession of water-power rights are often an important adjunct to the successful development of mining properties; and that without timber, however important it may be as a means of conserving the rainfall of a region, it would be impossible to operate many of our most important mines. It appears that any proposed legislation bearing upon the disposition of the mineral lands, lands containing water-power sites, or forested lands, which might discourage prospecting or make mining more hazardous should be carefully considered before being approved by this body.

The American Mining Congress has accomplished something in the years passed; what it may do in the future lies in your hands. You are here to outline a policy for the coming year. Remember, that it requires time and money to accomplish those things which you may outline and when you vote to have this Congress use its best efforts to secure some legislation and do not provide the means to carry on this work you are expecting an income without an investment.

In case you ask this Congress to do anything which requires expenditure of time and money, you will do well to accompany that request with some feasible plan whereby the necessary finances may be provided. It is an easy matter to provide a finance committee, but it is not easy for such committees to secure the funds required to defray the expenses of the association's activities. It may do some good to pass resolutions memorializing Congress to pass such and such bills, but if you earnestly desire the passage of any measure such resolutions must be followed by an active campaign, which requires both time and money.

This association was organized to teach mining men the value of co-operation; that success cannot be measured by another man's failure; that we must have a decent respect for the lives and health of the men that toil beneath the surface; that there must be a willingness to provide adequately for the men and their families who suffer through accident or death; that there should be laws to restrain and punish the man who is in part responsible for the disrespect in which this profession is held, the fake promoter, who parasites on the public; that all the Bureaus of the Federal and State governments, engaged in investigations associated with mining, are helpful and deserve our undivided support.

Conservation as it Affects Coal Lands

By E. W. Parker

*In the popular mind the cause of conservation had its beginning in the calling of the first conservation congress in 1907—and that was the time of popular awakening, but as has been recently pointed out by C. W. Hayes in an address delivered at Chicago, for a quarter of a century or more before the calling of that famous convention, thinking men had been studying the problem and had recognized the necessity for an abatement in the wasteful methods of utilizing our natural resources. Mr. Hayes calls attention to the great work of Major Powell, the second Director of the U. S. Geological Survey, and how the possibilities of irrigating, and thus reclaiming, or conserving, the use of the arid lands clearly and forcibly pointed out by Major Powell as early as 1878, found their realization 24 years later in the enactment of the Reclamation law of 1902.

Actual practical work in the conservation of our coal supplies was being carried on when many of those present were studying their grammars and geographies and knew little and cared less about the waste of natural resources. To the close of 1908 we had produced and consumed in the United States over 7,280,000,000 tons of coal, and that this represented (allowing half a ton of coal lost for each ton mined), an exhaustion of nearly 12,000,000,000 tons. When we consider that this has used up only four-tenths of one per cent of the original supply it does not appear that the United States will be suffering for fuel for some time to come. But it must be remembered that by far the larger part of the coal remaining is either low grade or accessible only with difficulty, and at greatly increased cost. We are taking the best and the most easily mined and we have been using it in a wasteful manner. We may look at the present increasing rate of production for the exhaustion of our high-grade and easily mined coal before the middle of the next century. Conservation of coal began in the anthracite region of Pennsylvania, where within a small area of less than 500 square miles is the most valuable supply of coal known in the world. The early method of anthracite mining, marketing, and utilization of anthracite was in the light of present knowledge, horrible examples of profligacy and waste, but probably as well as could be done under the conditions that existed at the time. Competition instead of being the life of the trade came near to being its murderer. Yet man was not nearly so wasteful as nature had been, for while nature had been generous in the first place she was more wasteful than her children, for it has been estimated that of the total supply of anthracite originally deposited only 6% remained when man began to utilize it. Back as far as 1883 or 1884 nearly twenty-five years before the calling of the first conservation congress, the necessity for the conserving of the remaining part of that six per cent of anthracite was borne in upon some of the thinking men engaged in the industry. When the movement, headed by Eckley B. Coxe, P. W. Sheafer, William Griffith, and a few others, began, it is doubtful if the recovery of coal was as much as 40%, 60% being lost, partly in the pillars left to protect the workings, partly in the small coal thrown on the culm banks and for which there was no market. The matter being brought to the attention of the Governor of the State he appointed the Anthracite Coal Waste Commission. The Commission made its report in 1887. It was the first conservation report, and as a result the waste in the anthracite region has been so diminished that now it is estimated that the recovery exceeds 60%. Moreover, in addition to the larger recovery at present, provision is made for subsequent recovery of a large part of the coal now left as pillars. This is practical conservation. In order to accomplish it, it has been necessary to put the industry under a close control and to eliminate competition except in so far as bituminous coal competes with anthracite—to create practically a monopoly of the anthracite supply, but I do not believe that this has resulted in any oppression of the people by extortionate prices. The average price of anthracite at the mine ranges from $2.25 to $2.35 per long ton and of this 40% of the output is of pea size and smaller which is sold below the cost of production.

The competitive conditions that formerly existed in the anthracite region still obtain throughout the bituminous producing States. Mine competes against mine, district against district, and State against State. Illinois is jealous of West Virginia; Iowa, Arkansas, and Oklahoma complain of unfair competition from Illinois coals. The New River, Kanawha, and Pocahontas districts of West Virginia are rivals for the same markets, and almost a trade war exists between the southwestern districts of Illinois and those of the southern and northern parts of the State. The effect is unwholesome. It is against the conservation of the coal, and worse than that, it is against the conservation of the lives and limbs of the miners. There is not sufficient margin between the cost and selling price of bituminous coal to enable the operators to mine the coal to the best advantage, nor to provide the proper appliances and superintendence to secure the maximum safety to the employees. This competition between States makes it impossible to secure the proper legislation looking to greater safety in the operation of coal mines, for the law-making body of one State is not apt to enact legislation which will place one of its important industries at a disadvantage with that in a competing State. Still less are the legislators inclined to enact laws that will restrict the miner in the exercise of what he considers his personal liberty.

I am convinced that the most crying need in the coal mining industry is the ability to enforce discipline among the mine workers. As it is now there is not, so far as I know, in any State, laws which make it a penal offense for a mine employee to put his own life and that of his fellow workers in jeop-

*Read before American Mining Congress, Los Angeles, September 26.

ardy. The only punishment meted out is the death or injury that results from the catastrophe. Coal mines of this country should be under as strict police surveillance, as they are in Europe, and both operators and miners should be made to obey the laws. One of the most reprehensible practices in the mining of bituminous coal is that of 'shooting from the solid' a practice that has increased through the custom forced upon the operators in some States—of paying for the coal on a mine-run basis. It results in 'making the powder do the work' of the miner and this adds materially to the liability to explosions from the quantity of dust produced and to the frequency of 'windy shots.' Moreover, the excessive charges of powder necessary weaken the roof and pillars. It is abominably bad and yet the State of Oklahoma has by act of legislature, put a premium on this kind of mining.

The shooting of coal from the solid and paying for the mining on a mine-run basis, except in cases where the slack coal may be used to advantage in the manufacture of coke, is anti-conservational in the production of a disproportionate quantity of either unsalable or undesirable coal.

When in the effort to conserve our resources, the expense exceeds the benefit to be derived, the cause has got to suffer. Much has been said about wasteful methods of making coke in bee-hive ovens and the fact is that the value of the gaseous content of the coal wasted each year exceeds $50,000,000. It has been a question whether it would not cost more than that amount to save it. Until recently the tar produced in the manufacture of illuminating gas has been a drug on the market and much of it has been thrown away or burned for fuel at the works. With the increasing scarcity and higher cost of railroad ties, however, there has been a notable increase in the demand for creosote oils, a product of the coal tar, for preserving ties, and the development of the coal briquetting industry in different parts of the country is creating a demand for the residual pitch. This is giving an impetus to the retort coke-oven industry, and in the course of time the bee-hive oven will disappear from the United States as it has disappeared in European countries. The change will be gradual as there is a large capital invested in bee-hive oven plants, but while the first by-product recovery plant of 12 ovens was put in blast in 1893, retort oven coke in 1908 was 14% of the total output. In our neighboring Republic of Mexico, retort oven plants have been erected in the State of Coahuila. The gases are utilized in the power plant, each oven yielding the equivalent of 16 hp. of fuel. A better grade of coke is obtained and at the same time a higher yield in coke. The ovens in the Connellsville and lower Connellsville districts of Pennsylvania would at the rate they get in Mexico, produce approximately 600,000 hp. every day in the year.

In coal mining as in other lines of industry the most effective conservation and economy can only be secured through the conducting of operations on a large scale. It is the large and not the small unit that is able to effect the greatest saving. The small coal mine is always the most wasteful.

It is only through such extensive operations as those of the United States Steel Corporation that the greatest efficiency and the maximum economy can be secured. The Steel Corporation, by the way, has erected in Indiana and Illinois, 280 retort ovens and contemplates increasing the number to 1000. The Cambria Steel Co., at Johnstown, Pa., which was one of the pioneers in retort-oven construction in this country, having built 60 in 1895, has now nearly 400 of them in operation, and I am of the opinion that most of the coke made by this company is made in by-product ovens.

The development of the coal resources of Alaska has been the subject of much discussion during recent months. Mr. Brooks has, in his latest progress report, shown how the Territory is suffering for the need of coal while its coal lies undeveloped for want of legislation to permit it. It cannot be accomplished when the unit of operation is limited to 160 acres. It will require the investment of a large amount of capital and it must be recognized that the mining operations and the transportation interests shall not be antagonistic, for the one must depend upon the other. Millions of dollars will be needed and in order to secure them the terms must be liberal, but there is no reason why the interests of the people might not be secured against monopolistic oppression. Is it wise conservation to allow these fields to lie undeveloped while West Virginia and Pennsylvania coals are brought to the Pacific Coast at a cost of half a ton of coal consumed in the transportation of each ton of coal carried?

Attempts to concentrate copper carbonates and oxides by wet methods have been unsatisfactory, for the reason that the valuable mineral slimes to such an extent that mechanical concentration seems to be a physical impossibility. Tin oxide (cassiterite) has a high specific gravity and when crushed is granular with no pronounced tendency to slime. Therefore it offers no unusual difficulty in concentration. Cinnabar is a sulphide of mercury, and although it is soft, concentrates far more readily than most soft minerals, by reason of its high gravity. It can be saved on any good concentrating machine. The Colorado 'bumping-table' has been known to do excellent work in concentrating ores containing cinnabar. In some instances dry concentrating machines have done better work in effecting a concentration of oxidized copper ores than could be done on the ordinary machines.

The copper shells of blasting caps weigh about 0.05 lb. each. That is, it requires from 450 to 500 shells to weigh one pound avoirdupois. In gold mines practically all of the caps employed in blasting in ore go to the mill with the ore and into the battery or grinding mills. Where amalgamation is practised these copper fragments are amalgamated with the gold, and eventually the greater part of it goes into the bullion bars. In a mine where 1000 shots are fired monthly in the stopes about 2 lb. of copper is present in the caps, and this mostly goes into the bullion, thus reducing its fineness.

Mine Accidents and the Bureau of Mines

By George S. Rice

*While it is evident that there is a great diversity of opinion among American mining men as to the proper functions of the new Federal Bureau of Mines, on one point, at least there appears to be general agreement, namely, that the investigation of accidents in coal mines, started under the jurisdiction of the Geological Survey should be continued, and that a similar investigation should be made of accidents in metal mines.

A prominent English mining engineer, while speaking of accidents in metal mines, remarked that coal miners were fortunate in having disasters occur in their mines. This, at first, seems like a brutal statement, but when the matter is considered carefully, the meaning becomes clear, since in spite of the large number of men who have been killed and injured in the great colliery disasters that too frequently have appalled the world, the number of deaths and injuries from this cause have formed only a small part of the total number killed and injured in coal mining by other causes, particularly those due to falls of coal and rock.

In 1907, the year of the greatest series of American colliery disasters, E. W. Parker reports 947 men killed and 347 injured in gas and dust explosions. During the same year in all the coal mines of this country, there were 1122 killed and 2141 injured from falls of roof or coal, and from all causes, the totals for that year were 3125 killed and 5316 injured. Therefore, of the total number killed and injured, less than one-third were killed and one-fifteenth were injured by explosions, in that year of greatest mine explosions.

In more normal years, like 1908, during which 2450 were killed and 6772 injured, only one-sixth of the killed were lost in disasters and one-twentieth of the total were injured by explosions of gas and dust.

Nevertheless, as previously indicated, the horror produced by the explosions has caused attention to be directed to accidents in coal mines, and the precautions taken on this account have led to a general improvement in colliery conditions; and in all civilized mining countries, except the United States, the accident rate has been steadily decreasing.

In the United States the annual accident rate of coal mining nearly doubled in the ten years from 1897 to 1907, when we attained the high annual death rate of 4.86 deaths per 1000 employees. Fortunately, the year 1908 showed a reduction to 3.60 deaths per 1000, and in 1909, the death rate was still further decreased. We can only hope it will continue to decrease. The present rate is most appalling when one considers it, particularly in comparison with that of France or Belgium, where the annual mortality rates are but 1 per 1000.

In view of the high accident rate in the collieries of this country, it might be questioned if the attention attracted by the disasters has led to much improvement of conditions. Undoubtedly there has been improvement, but it has not, until 1908, kept pace with increased dangers due to rapid development and greater natural dangers arising from greater depth of workings with consequent increase in flow of explosive gas and the increased use of black powder in lieu of pick work.

Metal Mining Accidents.—When attention is directed to metalliferous mining accidents, it is surprising to find that many of the States in which mining is done make no record of the deaths and injuries in metal mining, and the Federal government has hitherto made no attempt to gather such statistics.

This strange lack of information cannot be because the metal mine operators as a rule are less interested in the welfare of their employees; there are many instances to show the contrary.

It is noticeable that the States that do not gather mine accident statistics are chiefly those in which there is no coal mining. Coal miners and operators, in going from the old established coal mining centres of the East and from Europe have carried with them their customs and systems of law and regulations which include the recording of mine accidents.

Metalliferous miners in this country have largely formed their own precedents, and, probably due to the wide diversity of mining systems, there has not been the same community of interests among miners until more recently. Your committee on uniform mining laws and prevention of mine accidents, in its report to this Congress, has clearly brought to attention the lack of metal mining statistics, except in certain States and those States have the best mining laws.

Frederick L. Hoffman, the well known statistician, has done valuable service to the metal mining industry in attempting to obtain, in spite of lack of official statistics, the fatality rates in different parts of the country. I will not attempt to comment on his report, except to call attention to the fact that he finds the average rate is practically the same in metal as in coal mining, despite the general acceptance that the natural conditions are less hazardous. His figures also show that there is a greater variation in different metal mining districts than in different coal mining districts, and that the accident rates in both are appallingly high as compared with those of European countries.

Attacking another phase of the conditions under which miners work, Mr. Hoffman in an article in *The Engineering and Mining Journal*, July 2, 1910, has commented upon the excess of sickness and ill health of miners as a class, compared with those who work in the open air.

Haldane and Thomas Paper on Miners' Diseases.—J. S. Haldane and R. A. Thomas, in an article which appeared in the Transactions of the Institution of Mining and Metallurgy, volume 13, reached the conclusions after a study of the health statistics of miners and others living in England, Wales, and Cornwall; that apart from lung diseases and a slight excess of fatal accidents (many of which are not un-

*Paper read before the American Mining Congress.

dergrounds), metalliferous mining in England is a healthful occupation.

Haldane and Thomas found that the mines that they examined in Cornwall were freer from gaseous impurities than the air of coal or iron-stone mines. They discussed three possible causes: (1) The stone dust produced. (2) The smoke produced by explosives. (3) Infectious bacteria.

They decided that infection by tubercular bacillus will not explain the facts relating to miners' phthisis. They considered that the smoke from explosives and candles was probably inappreciable. Their final conclusion was that the inhalation of coal dust was the cause of the lung disease which is common among the Cornish and other miners. They state that out of 142 men who had worked rock drills in the Cornwall district, 94% died of lung diseases and the average age at death was 37 years, and of 178 men who did not work with rock drills, 65% died of lung diseases, but the average age at death was 50 years. They, therefore, considered that the introduction of rock drills in Cornwall is responsible for the recent great increase in the mortality of Cornish miners between the ages of 25 and 50 years. They thought that the dust produced its effects upon the lungs mechanically, by its hardness, sharpness, and insolubility. In a discussion which followed the Haldane and Thomas paper, Dr. Oliver stated that miners' phthisis belonged to a group of diseases in which the spongy texture of the lungs became converted into a hard solid tissue. R. J. Watkins, who had charge of a sampling mill, stated that when certain kinds of dust were sampled, men were knocked out often for many days, and that a sulphide ore of certain composition gave the most trouble.

Much attention has been paid in South Africa to miners' phthisis, and in 1902 prizes were offered for the three best practical suggestions and devices for obviating, minimizing, or combatting the causes leading to miners' phthisis. It was stated that while no definite information was before the Commission, it was generally assumed that the cause of the disease lay in the inhalation of fine dust produced by rock drills.

Two hundred and twenty-nine competitors responded. Most of the suggestions were regarded as impracticable methods for wetting, through jets, the dust as made by the drill, and atomizers or sprinklers for laying the dust when made, received most attention, and some of the devices were regarded by the Commission as promising.

In addition to the menace of stone dust it is evident that in some mines and in some places, where there is no positive, or little ventilation, the breathing of gases from the combustion of explosives produces an unfortunate influence upon the men, which at times has been accumulative in its effects. We know from the work which has been done by Haldane and others the poisonous effects of minute quantities of carbon monoxide which is absorbed by the blood in lieu of oxygen, and if a man is continuously exposed he rapidly succumbs. This is the case when there is over 0.3 of 1 per cent in the atmosphere. Moreover, recovery of one partly poisoned is slow. It seems probable that when a man is regularly exposed to small quantities in the air, he may become in time incapacitated.

With nearly all high or quick explosives on the market, carbon monoxide forms a large portion of the gases of combustion. From time to time we hear of men being overcome in the mines by such gases and in some instances even being killed—notably the case that occurred in the Gunnison tunnel, in Colorado, on January 16, 1910, when a shift of men while waiting for the smoke from a round of 50 holes to clear, were overcome and nine of them died, evidently due, according to the facts as reported by the engineer in charge, to monoxide poisoning.

Investigation of Mine Accidents by Bureau of Mines.—Under the terms of enactment of the Bureau of Mines, the investigation of coal mine accidents started under the jurisdiction of the U. S. Geological Survey will be continued by the Bureau of Mines. This investigation consists of testing of explosives for use in gaseous or dusty mines (those that pass being listed as 'permissible' explosives), the investigation of safety-lamps and of rescue apparatus of all kinds: the establishment of rescue stations for the education and training of miners in the use of rescue apparatus; the investigation of mine disasters by mining engineers, with a view to finding preventives; the study of the humidity of mine air in its effect upon the drying or moistening of coal dust; the collection and analysis of mine gases and study of their sources and changes of efflux from the strata; the study by electrical engineers of the different phases of mine installations with a view to lessening the dangers therefrom; and the collection by the mining engineers of samples of coal throughout the country, which while partly for governmental fuel supplies, is also of service in connection with mine accident work, through the relation of the coal to the production of dust and gas.

The foregoing work has in the past been carried on by a well equipped laboratory at Pittsburg, aided by a small field force of mining engineers. Much time has been occupied in purely educational work among the miners and foremen. It is proposed to continue all this work and possibly to enlarge it slightly from time to time as funds may be provided by Congress, to better cover the widespread coalfields of the country.

Under the law establishing the Bureau of Mines, the scope of the work has been enlarged, and the investigation of mine accidents has been extended to cover both quarries and metalliferous mines. It is expected that mining engineers who have been already connected with mine accident investigations, will extend their observations as far as possible to quarries and metalliferous mines. The appropriation for this year will allow but few additions to the force, but if the results justify, it is not improbable that Congress will provide for extension of the work in the future.

It is manifest that there is ample room to do good work in the investigation of the metalliferous mine

accidents, particularly in studying in the field the effects of stone dust and of gases arising from the discharge of explosives, and at the Pittsburg station in the study of the explosives used in metal mining, with a view to obtaining such explosives that the products of combustion will be less harmful to the health of the miners.

In another direction, in quarries and in metalliferous mines, the gathering of statistics of accidents by a Federal bureau, working in conjunction with State bureaus, a work hitherto ably done by E. W. Parker for coal mine accidents, will be of great value, inasmuch as it will lead to precautions being taken to prevent many accidents, the causes of which are often overlooked. Unification of the methods of gathering such mine accident statistics will also be of value inasmuch as it will enable the intelligent comparison of similar kinds of accidents in different districts and countries and thus lead to betterment of conditions. Besides this valuable feature there is another. It is the tendency of the times to look forward to a time when each industry will bear the load of caring for its killed and injured. Already a number of progressive mining companies have started insurance organizations, the cost of which is borne partly by the employees and partly by the companies. In any case, there can be little question that if an industry is in a thoroughly healthy condition, it should be able to bear the cost of caring for those injured in its business, and for the pensioning of needy widows and orphans. As a matter of common humanity, this proposition can hardly be disputed. If conditions prevail otherwise, it means that the price obtained for the product should be raised to meet this condition. No doubt this movement must be gradual to not disarrange business conditions.

There are forms giving suggested classifications of accidents in metal mines and coal mines. These classifications are not in any sense final, but are put forward for discussion. They follow to some extent the English system, though a little more elaborate. It is only by close sub-division that analysis of the causes of accidents can be made satisfactorily. In another matter the Bureau of Mines may be able to give valuable aid; namely, in promoting the unification of mining laws and regulations, such as those proposed by the several committees reporting to this Congress.

There are doubtless many problems in connection with mine accidents which are not mentioned in this paper, and of which members of the Bureau of Mines staff will be glad to learn from the mining engineers of the country. While the question is complex it is worthy of our best efforts since it deals with the lessening of loss of life and limb.

The National Bureau of Statistics of the Department of Commerce and Labor reports that the export of mineral oil from the United States for the month of July was 112,402,879 gal. worth $7,332,417. The total export of mineral oil for the first seven months of 1910 was 799,565,564 gal. valued at $51,560,226, which was 50,587,324 gal. less than for the corresponding period of 1909 and $6,289,102 less in value.

Chico, Mexico

The Chico mining district in the State of Hidalgo promises soon to come into prominence and may eventually be a rival to Pachuca. It is only six miles north of that city and is reached by an excellent wagon-road. The Sierra of Atotoniles or 'Mountains of Pachuca' form the great barrier range of the northern end of the Valley of Mexico, and consist of a mass of intrusive rocks which have broken through, and largely cover, the earlier Cretaceous sediments. The general direction of the range is northwest; the greatest length is 28 miles, and the width varies from 10 to 14. The highest points reach an elevation of over 11,300 ft., one of the most notable peaks being Las Ventanas, a great mass of serrated rocks, reaching a height of 10,830 ft. This peak forms a land-mark about half way between Pachuca and Chico. The southern slopes of the mountains merge gradually into the plains of the Valley of Mexico; but the northern are more abrupt and broken, dropping rapidly to the lower levels of the Grand Cañon, the drainage plain of which is several thousand feet lower than the Valley of Mexico.

Pachuca, which is on the southern slope, has a comparatively dry and arid climate and there is little vegetation in the neighborhood. Chico, on the northern slope, has a rainfall about 70% in excess of that of Pachuca, and the country is fertile and well wooded. The deep gorges resulting from the extensive erosion on the northern slope have in some cases exposed the Cretaceous slates and other sedimentaries. Some of the veins at Chico are along contacts between slates and andesites. The average gold content of the veins of the Chico district is about twice that of the Pachuca veins. The veins are also generally much wider; with these exceptions, the geological features of the two camps are similar. The massif of the range is formed of close grained andesites and porphyries. Spurs to the south consist of breccias and highly altered tuffs, the remains of earlier eruptive activity. There are extensive remains of more recent rhyolitic and basalt flows which form sharp escarpments where cut through by erosion.

The Chico vein system is the result of one main fracture zone which strikes approximately east. Most of the veins dip south. There are two main veins in the zone, the Arevalo to the north, and the San Pedro or Veta Principal to the south. These veins are approximately parallel. The gangue of the veins is quartz and calcite, the siliceous matter predominating. Both free gold and native silver occur. Gold is also associated with iron pyrite and found as an alloy with silver. The silver occurs as argentite, proustite, stephanite, etc. There are traces of manganese. Various tests have been made showing that the ores are amenable to cyanidation. Extractions as high as 86% silver and 97 gold have been obtained.

Records in the archives of the church at Chico show that the Spaniards started mining in 1521, and

there are traditions culled from old Spanish writings of the mines being worked by the Toltecs in pre-Aztec times. It is stated that evidences of some of the old Indian workings can still be found. It is estimated that there are 28 miles of Spanish workings on the Arevalo vein. One of the early Spanish owners, on the occasion of the marriage of his daughter in El Chico church, paved the street with bars of solid silver (each worth ₱1200) from the door of his house to the church, a distance of 280 ft., so that the bridal pair should walk on solid silver from the home to the church. The Arevalo mine has the unique record of having been operated continuously for over one hundred years without a shut-down, and today the workings have reached a depth of over 350 metres, without the vein showing signs of exhaustion.

The mines have been worked without any regular system or method, and even during the last 50 years nearly all the ore has been taken out by the *buscon* system or tribute work, the lowest grade that was mined and brought to the surface having 32 oz. of silver or over per ton. The value of the gold contained was disregarded as practically none of it was saved by the methods of treatment in vogue. In the early days the ore was treated by *chacuacos* or Indian furnaces, and by the patio process. There were a number of these *haciendas* running until recently. The greater part of the high-grade ore has been purchased during recent years by ore buyers for smelters in other parts of the Republic. A large tonnage of milling ore amenable to cyanidation is known to exist in the various mines, and as soon as modern mills and cyanide plants are erected, there is no reason why Chico should not become as famous and as prosperous as Pachuca.

The principal owners of mines are as follows. The Compania Metalurgica de Atotonilco, the Amalgamated Mining & Milling Co., Sr. Julian Perez Duarte, the Fortuna Mining Co., the San Marcial y Anexas Mining Co., R. H. Lyman and associates, and various other mining companies and individuals. The first of these companies controls about 170 hectares of land, which includes the Arevalo, Aurora, Nepturano, Pluton, La Union, Nueva Digue, Jesus, San Rafael, San Cayetano, and Nepton mines, the Nepton adit, and the Plan Grande mill. With the exception of the work in the Nepton adit this company is operating on the most primitive plan. Mining is carried on by tribute, and the ore is sorted first underground by the miners and then on the surface by women. It is handled at least six times before reaching the mill or being sent to the smelter. The mill is driven by water-power, developed by an overshot water-wheel. Chilean mills are used for grinding. The old patio process is still used in combination with concentration of the tailing on English buddles. Losses amount to 20% of the silver and 85 of the gold. In spite of this the mines have given a total return of over ₱10,000,000.

The Amalgamated M. & M. Co. holdings are the largest in the district, covering 162 hectares, and including part of the Veta Principal, which at that point is 30 ft. across and averages 1200 grams silver and 9 grams gold per ton. The company has no mill. The ore is hoisted by horse-whims and sorted, the high-grade being shipped to the A. S. & R. Co. at Aguas Calientes. The net profits are about ₱20,000 a month from the high-grade ores. A large tonnage of low-grade ores is available.

The Julio Perez Duarte properties are at present being worked on a very small scale but as the Nepton adit has drained the workings, plans are being formulated to push the work.

The Fortuna is a small company formed by local merchants and employees. They started operations three years ago with a capital of only ₱5000. The money was judiciously spent in clearing out an old drift and in development, with the result that they cut one of the principal veins, and five others have taken out over ₱25,000 in high-grade ore. This has all been reinvested in development. A large body of good milling ore is available, but like other companies in the district, this is handicapped by lack of capital and milling facilities. The holdings cover 40 hectares.

The San Marcial y Anexas holdings cover 54 hectares. The property is not being worked at present, pending legal decisions and a settlement between the heirs of the late principal owners. The vein is on a contact between andesite and rhyolite and can be traced for about six kilometres. It measures from 40 to 50 ft. wide and has been famous for its high-grade shipping ore, some of the highest grade found in the district running from ₱8000 to ₱9000 per ton, having been found in this mine. During nine years that the mine was in operation, a total of over ₱2,000,000 was produced. This is the only mine in the district in which ruby silver is found.

R. H. Lyman and associates have, next to the Amalgamated, the largest holdings in the district, covering an area of 134 hectares. The veins are all on the contact, the most promising is the Veta Principal, with a width on the croppings of over 85 ft., strike east, and dip of 65° to the south. This vein is the most southerly of all the Chico systems and is parallel to the Viscania in the Pachuca district. The two veins are respectively on either side of the great mass of andesites that form the backbone of the mountains dividing the Pachuca and El Chico camps. The holdings include a number of other valuable veins, the most important of which will be drained by the Nepton adit. This important work is being pushed with considerable vigor. The adit measures 14 by 14 ft. and the average progress made is 130 ft. per month. The total length driven to date is 2170 metres, and with 40 more, it will cut the Arevalo vein at a depth of 370 metres. It will eventually cut the San Pedro vein at 450 metres. Up to the present time, 56 veins have been cut by the adit and it will undoubtedly prove one of the most important factors in draining and developing the district.

Never tamp powder in a drill-hole with an iron spoon or metal bar of any kind. If the wooden bar is too thick to reach the bottom of a deep hole, get one that is of less diameter, or have the larger one worked down to proper size.

Testing Placers in Korea

By R. Y. Hanlon

Recently I have had occasion to examine a placer deposit which differs greatly in its physical characteristics from those found in western North America. The method finally adopted of drilling this deposit was rather unique. The placer is a marine deposit formed at a time when the peninsula upon which it is situated was submerged, the ground having risen gradually until the deposit is now 30 ft. above sea-level. At the outset it was decided to employ a hand-drill of the regulation type, using 4-in. nominal inside diameter gas-pipe. The drills, cutters, and pump were made in a local blacksmith shop by a native Korean smith. This method of working was found to be subject to grave objections on account of the fact that it was not possible, with the paucity of tools at our disposal, to make a sand-pump capable of removing the entire content of the drill-hole, and the greater part of the deposit consisting of sand, the pump tended to ram the material tight rather than lift it. The following scheme was eventually decided upon.

The capping of soil and clay was bored through with a clay auger of 5.5 in. diam., and as soon as the wet sandy strata underneath were entered, usually at a depth of from 8 to 12 ft., the pipe was inserted and driven directly into bedrock, a distance of 18 to 23 ft. below the surface, or a total drive of about 11 ft., if we allow a one-foot core of bedrock. During the driving, which in the early stages was done by one man with a mallet, and in the tighter bottom gravel by four men with a pile-driver, the pipe was rotated continually in order to hasten its progress and facilitate its removal.

Owing to the fact that the stratum of pay gravel, from 2 to 4 ft. in thickness, was tight and nearly as compact as the decomposed schist bedrock, it was rather difficult at first to know just when the pipe had penetrated the bedrock sufficiently, for, with too thick a bedrock core, it is difficult to extract the pipe, and, if the penetration was only a few inches, there was every possibility that the core would drop out of the pipe during the process of pulling out the latter. Several holes were lost on this account, until the men became familiar with the sound when bedrock was struck.

With a foot of bedrock as a plug the time consumed in pulling the pipe from a 20-ft. hole was rarely more than one-half hour, and often less than 20 minutes. The pulling was accomplished by bolting two 4-in. round timbers to the pipe in such a manner that they projected 4 ft. upon either side, thus furnishing a species of 'bull ring' and also two handles for turning the pipe during its removal. A 4-in. squared oak timber was used as a lever. The core for each hole was washed out into metal tubs and panned, the core of each stratum being panned and noted separately for the purpose of learning the position of the richest gravel.

Drilling in Alluvial Ground in Korea.

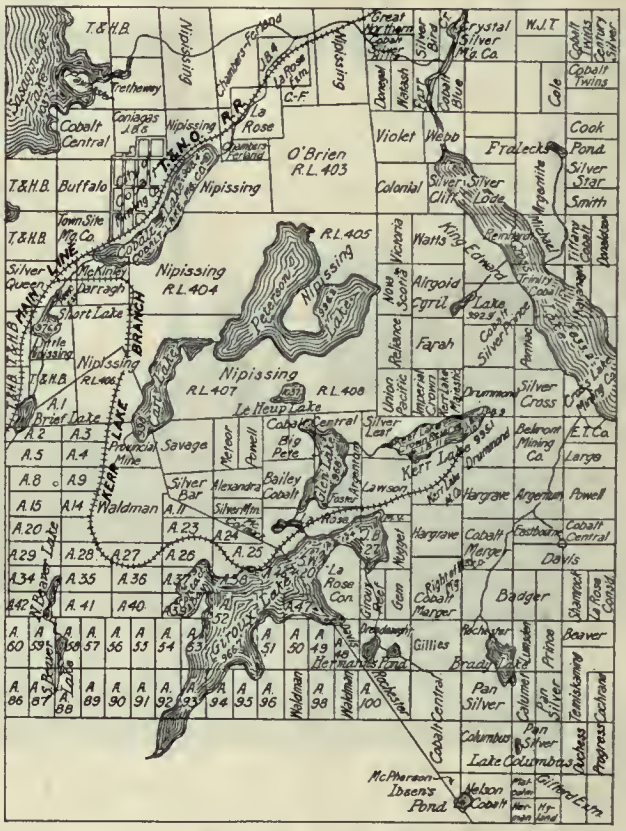
Seventy-five holes averaging 18 ft. in depth were sunk with two drills by the above method in 26 actual working days at an average cost of 20c. per lineal foot. Of the above holes five were re-drilled, four on account of a lost core due to insufficient depth, and one due to a rock larger than the inside diameter of the pipe. A true core was always obtained and the calculated and measured content checked excellently when assuming a diameter of 4.5 in. It may be objected that the pipe used was of rather small diameter, but I am of the opinion that, in a given area, two 4-in. holes will give more reliable information than one 6-in. hole, and in ground similar to that described above can be drilled as cheaply as the holes of larger diameter. It is proposed to supplement this work by sinking shafts.

Mining Laws of Quebec and Ontario

By Theo. F. Van Wagenen

General.—The mining laws of the provinces of Ontario and Quebec are obtainable in pamphlet form from the Minister of Mines at Toronto and at Quebec, which are respectively the capitals of the two provinces. The pamphlet containing the mining laws of Ontario consists of 118 pages, and of Quebec 45. In addition, the Quebec Department of Mines issues a small pamphlet of 32 pages called a 'Miner's Guide.' In making an abstract covering the main features of these two laws I have spent twenty hours of close application upon that of Ontario, and eleven hours on that of Quebec, and am not yet sure that either are thoroughly understood. Both are complicated, and entirely beyond the comprehension of the ordinary reader; and of course, to the average prospector, the man who is really the discoverer of mineral indications or outcrops, the pamphlets might as well be non-existant. Unfortunately this is the case with all mining laws except those of the United States. They are prepared by lawyers, or by mining engineers collaborating with lawyers, and the result invariably is the production of a document so full of unnecessary detail, so hedged about with provisos, exceptions and penalties, and so burdened with conditions difficult or wholly impossible of execution by the prospector, that he immediately abandons the field—if he ever enters it—to the 'claim pegger,' who is an entirely different type of an individual and by no means as desirable. It is strange that this mistake is so constantly being repeated in mining countries all over the world, even in parts of our own land (Texas and Minnesota), where the Federal law does not apply. Miners of the mountain and coast States who have the good fortune to be able to operate under the simple national law have reason to be extremely thankful.

Ontario Mining Law.—Any male person over the age of 18, whether possessing British citizenship or not, may obtain the right of prospecting on the public lands of the Province (both surveyed and unsurveyed), and on all private lands where the Government has only parted with the surface rights thereof, by purchasing from the Minister of Mines of his deputy, or any mining recorder, a miner's license, which costs the sum of $5; but, if he wishes to prospect on private lands, he must in addition give a bond to the Minister of Mines, or deposit a cash sum with him, to secure the surface owner against any damage that may be caused by his operations. This license is good for a year, but may be renewed as often as desired by the payment of the annual fee. It is not transferable, is not good for the prospector's partner, must always be carried by the individual to whom it is issued, so that it can be displayed on demand by an inspector or recorder, or any rural police officer, and if lost or destroyed by accident may be replaced at the cost of $1, upon furnishing proper proofs of identity. With this document, the licensee may locate up to three claims, each of which must be 40 acres in area. A license may be issued to a partnership, and also to a company that has been duly incorporated, but neither may purchase more than one license per year. The right is reserved by the Minister of Mines to proclaim a field as a 'Special Mining Division' at any time, whereupon the size of the claim is cut down to 20 acres, and the total to 60 acres. All claims must conform in shape and position to the legal subdivisions where the country has been surveyed, or, in unsurveyed regions must be rectangular, with their sides pointing to the astronomical north, south, east, and west. No extralateral rights are allowed. The process of staking is simple, and consists of erecting a discovery post and four corner posts, of



Claims at Cobalt, Ontario.

blazing the line from the discovery to corner 1, and then the lines around the block.

Recording must be done within 15 days of staking, but if the ground is more than 10 miles from the recorder's office, an additional day is allowed for every extra 10 miles or fraction thereof. A sketch map and considerable descriptive detail must be furnished by the prospector, and the recording fee is $10 per claim. A memorandum of each claim recorded must be made by the recorder on the back of the license. The recorder has the right, after accepting the recording fee, to refuse to record, if, in his opinion, there is anything wrong. In such a case an appeal may be made to an official called the Commissioner of Mines, on payment of an additional fee of $10, and a few small charges connected with the preparation of the appeal papers. After recording, a period of 60 days occurs during which the location must be passed upon by an inspecting officer.

who has the power to reject it if it is erroneously staked or described, or if, in his opinion, no discovery of payable mineral has been made. For several other reasons it may be disallowed, but if it is passed, the licensee is given a 'Certificate of Record' upon payment of a fee of $1. This certificate is regarded as prima facie evidence of a good title for prospecting purposes.

To maintain such a location in force, the licensee must do 30 days work (of 8 hours each) upon his claim during the 90 days succeeding the date upon his certificate of record. During each of the first and second years thereafter he must do 60 days work, and during the third year, 90 days. All this work may be completed at one time, or in shorter periods, if desired. As the work for each period is finished, an affidavit to that effect must be executed and filed, and in each case a 'Certificate of Performance' will be issued by the recorder, upon payment of a fee of $1, if, in his opinion, the work has been properly done. If the certificate is refused, there is an appeal to the Commissioner, whose decision is final.

Within three and a half years from the date of the Certificate of Record, a patent must be applied for, or the claim is forfeited. The cost of patenting is small, the main item being the price for the land, which is $3 per acre in surveyed territory, and $2.50 in unsurveyed. The patent, when issued, does not convey the timber on the surface, nor any water, or water-power on it. Boys under 15 years of age are not allowed to perform underground work, and boys under 17 may not be employed on Sundays, nor for more than 8 hours during the 24 on any day of the week. No royalty is charged or collected on ore or metal extracted and sold from the claim, and when the patent is granted a fee simple title passes from the Government to the miner.

Quebec Mining Law.—In this Province the first step is the purchase of what is called a 'Miner's Certificate' which costs $10 and which gives the holder substantially the same prospecting rights as in Ontario for $5. The Quebec prospector may locate up to 5 claims of 40 acres each on his certificate, per year, and this certificate is renewable from year to year, as long as the prospector wishes to pay the annual $10 fee. The claim is a rectangle of 40 acres, laid out with boundaries due north and south and east and west, and no extra-lateral rights are allowed. As soon as the claim is staked the Minister of Mines at Quebec, or his nearest representative, must be formally advised by mail of the fact, and the 'Certificate' must be sent or brought in to have the memorandum of the location endorsed upon it. Within six months from the date of staking, the prospector must apply for a 'Miner's License' on his claim or claims, each one of which costs $10, plus $1 per acre per year, so that a 40-acre claim costs $50 cash per year to keep in force. No annual work is required. No patent is granted. Locations are transferable only with the consent of the Minister of Mines. The latter has also the right to substitute a royalty for the above mentioned annual fees, but this royalty cannot exceed 3% of the value of the ore at the mine, after deducting the cost of extracting it. A license must be obtained to put up any kind of ore-treating plant except such as may be operated by hand-power, the fee for the license being $5.

Comparisons.—In both provinces the miner is required to make out statistical returns early in January of each year, to the Minister of Mines, giving the number of men employed, the class of work performed by each, the wages paid, the mineral extracted, the proportion of it sold in the crude condition, and the proportion dressed or concentrated or otherwise beneficiated. Reports to this effect may be demanded of him monthly, at the discretion of the Mining Departments. There are also long lists of 'regulations' connected with the underground operation, the use of explosives, the housing of workmen, the payment of wages, etc., all good in themselves, but generally difficult of execution in the wilderness. It is therefore easy to understand why prospectors are hard to find in Canada, and why the exploration and development of the vast region around Hudson's Bay has proceeded so slowly. It is now over twenty years since the copper-nickel deposits of Sudbury were discovered, and more than five since the silver mines of Cobalt came to light, and these represent really the only two proved mineral fields of eastern Canada. Both were discovered by accident, by laborers engaged in grading for railway companies. Of late, we have heard of more or less excitement at Larder, Porcupine, Gowganda, and a few other points to the north of Cobalt, but the bulk of the work at these places is that of claim peggers, operating in conjunction with stock and share promoters in Toronto, Montreal, and Quebec. It is doubtful if there is a prospector (as the term is understood in the United States), in the whole of eastern Canada, and it is safe to say none will go there until the laws are altered. The genuine prospector, the real discoverer of new mineral fields and mines, is invariably a poor man, quite unable to pay for the privilege of looking over a country, inexperienced in business affairs, without clerkly capacity, and utterly incapable of carrying out the provisions of such laws as those from which the above extracts have been made. He is also a rather independent person. It may be justly claimed that he is exclusively an American institution, the result of our extremely simple and liberal mining law. He wanders by the thousands during the prospecting season all over the West and in Alaska, each year making discoveries in fields that are already the most actively worked of any in the world, but he stops abruptly in his journeyings at the lines of Mexico, Texas, Kansas, Nebraska, the Dakotas, and Canada, refusing to explore in places where he has to pay for the privilege by purchasing a license, or where the regulations connected with making a location and maintaining a title are complicated, expensive, or burdensome, and impose obstacles to the quick sale of his prospect, for the prospector is an explorer and discoverer, and not a developer. He is at the foundation of the industry, and the mining law must be drawn so as to allow him his reward.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

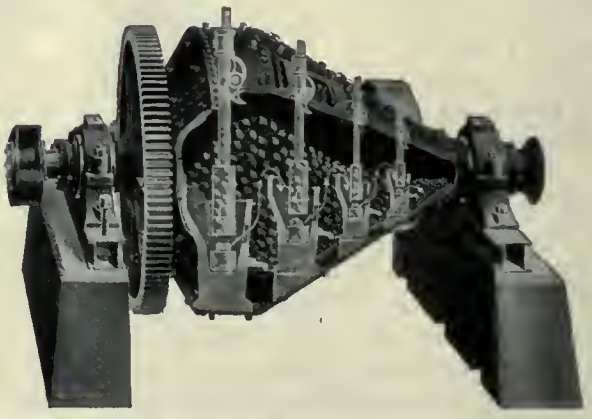
Crushing by Stages

The Editor:

Sir—As the indirect cause of a most animated discussion as to the real and supposed merits of the range and efficiency, or if you will, the inefficiency or inability of the conical pebble-mill to fill all gaps and delinquencies of all other fine-grinding machines to which the metallurgist falls heir, I have read with a parent's interest the discussion that has been going on for some weeks in your issues, between Felix Cremer and Algernon Del Mar. I would hardly be human did I not feel kindly toward Mr. Cremer in his advocacy of my 'baby.' He frankly states that the child looks healthy, pats him on the back and encourages him to win a place among the grown-ups, while Mr. Del Mar takes the position that even though his body is formed on correct lines, he does not believe that he will be able to hold his own. Then comes Stuart Todd into the discussion, in which he refers to a Hardinge conical mill as a single-coned mill. Every conical mill, so far built by my company, was and is double coned. Some time since we felt highly flattered, though we must confess a little annoyed, to find that our child was attracting the attention of the kidnaper. We now allow him to run the streets alone, for he has gained so many powerful friends that we have no longer fears for his safety.

Mr. Del Mar is right when he says that he believes the conical mill has its limitations. In this 'it is almost human,' at the same time we believe he is wrong in advocating two tube-mills and intermediate separation, as preferable to such 'stage reduction' as is obtained in the conical mill, for the reason that he uses the same mediums for further finer division of particles which have already divided them in the first mill. The principle of economy involved in all reduction is to successively reduce the energy as the particle is divided, for the energy necessary to divide a mass of matter is directly proportional to the particles of the mass, hence each division will require the application of less force. Again we will agree with Mr. Del Mar that stamps of 2000 lb. are encroaching upon the work of the rock-crusher, and one of 850 lb., that of the sliming machine. The 'stamps' we would advocate, based upon our experience during the past few years, should begin with a ball of 12 to 15 lb. weight acting directly upon the rock-crusher product and pass the resulting mass to gradually reduced weights down to one pound, or less. By figures, it will be ascertained that this one-pound ball has more effective action upon a 12-mesh particle than the 2000-lb. stamp upon a 2-in. cube of quartz; the latter system has a weight relation of about 2500 to 1, while the former is more than 20,000 to 1. It is the step reduction, such as this, that underlies the principles involved in the conical mill.

The real efficiency of any step reduction will be in direct proportion to the hard crushing surfaces exposed. Crushing with stamps involves the principle which confronted every metallurgist in his first ore reduction effort on the bucking-board. He will remember how he constantly cleaned the board, sieved and returned the coarse material for further reduction—not that he was seeking out any great principle, but simply knew he was expending unnecessary energy for which he was paying. After a few vigorous rubs, and a few drops of 'elbow grease'—from his brow—he sought the course of least resistance by cleaning his bucking-board and presenting a clean, hard surface for final reduction. Again we must agree with Mr. Del Mar, in theory, but in practice it would work about as follows: The stamp exposes crushing surfaces of shoe and die of about 60 sq. in. each, a total of say 120 sq. in., or in a stamp of 2000 lb. about 16 lb. of weight for each



square inch, this stamp with a 6-in. clear drop above a 2-in. cube of quartz, will (provided the die is clear of other material), easily reduce this size of cube to a fractured mass, the average of which will be finer than particles or cubes of less than ¼ in.; a reduction of 512 to 1. Reasoning upon this line, and as stated above, crushing resistance being proportionate to the particles of the mass, the next stamp in the series would be approximately 1/500 of the original, or a 4-lb. stamp. This we propose to furnish in a 3-in. ball with a crushing surface of 27 square inches, or 7 sq. in. of crushing surface for each pound of weight, or relatively 13,000 times that of the stamp, to say nothing of the proportionately increased amplitude of drop, which in the case of the '4-lb. stamp' again multiplies its efficiency many times. This relation of stamps to the multiplicity of balls, the decrease in the weight of the stamps to the decreasing weight of balls, and height of drop of stamp, offset by amplitude of fall or roll of balls, is illustrated in the following cut of a conical mill and a battery of stamps of different weights.

Even stamp advocates it would seem, must admit that ideal step-reduction would be successively reduced weight of stamps to crush material proportionately reduced. Even the smallest stamp illustrated, if it weighed but 100 lb., a ratio of 1:10, with the 1000-lb. stamp, would have an increased relation to the size of material to be reduced in its succession, as the fourth power of 500, or millions of times

greater than the original 2000-lb. stamp to its 2-in. cube. Thus, it will be seen that even the practice obtained in the conical mill does not come anywhere near its theoretical efficiency owing to the interference of the already finely comminuted particles. At the same time it is a long step in the direction of automatic adjustment of power to work performed. We are of the opinion that this matter of exposure of clean, hard, crushing surface, deserves careful consideration by the mill-man, especially as metallurgy through the production and utilization of low-grade ores, is assuming a position of industrial manufacturing importance, in contradistinction to the uncertain occurrence of high-grade ores with which mining has generally been associated. We are acquainted with an instance where an additional saving of $^1/_{10}$ of 1% of copper content per ton is the basis for reconstruction of a plant involving the expenditure of a very large sum of money. This saving of an additional $^1/_{10}$ of 1% seems small, yet in the case under consideration means a net gain of over $500,000 per annum at a lesser net cost than that at present.

H. W. HARDINGE.

New York, September 30.

Annual Labor

The Editor:

Sir—The time is approaching when the annual assessment work must be done on unpatented mining claims. Will you define what constitutes legal annual assessment, and can I charge the expense of reaching my mine to this?

CLAIM OWNER.

Stockton, California, August 1.

The object of annual assessment on unpatented mining claims is to advance their development and thereby enhance the value of the property, incidentally promoting and stimulating the mining industry. The law permits actual work in the development of the claim to be charged to this account, but traveling expenses to or from the mine are not a proper charge, nor can the expense of maintaining a watchman at the property be credited to it. Excavating an open-cut, driving an adit, sinking a shaft, or doing any underground work on the claim, or in its vicinity, and even outside the boundaries of the location, are a proper charge, provided that in the latter case it can be shown that such work is actually for the direct benefit of the claim, such as a cross-cut adit. Machinery of any kind placed on the property may also be properly charged to annual labor. It must be remembered that no matter how much labor or improvements are placed on a mine in any one year, no more than $100 can be charged to the account of each claim benefited thereby, for that year. In other words, if $1000 be spent on a claim in the year 1910, no part of it can be credited to it for the year 1911. For this reason and to economize traveling expense some claim owners take advantage of the opportunity to perform a hundred dollars' worth of work on a claim in December for one year, continues the work into January to do the work for that year also.

Engineering Advice

The Editor:

Sir—There are those who believe that the services of a mining engineer are of value only when a mine is to be examined, a report made, and a prospectus written with the report, more or less elaborated, as a basis for the statements made therein. The average mine owner, whether he be a prospector, a miner, or merely a 'business man' who has bought a mine, not unusually feels confident in his ability to plan the equipment and development of his property without assistance from an experienced engineer. True, some of them do remarkably well, but these are the exception, for ordinarily these self-sufficient gentlemen make mistakes which cost them 'a pretty penny' later on. I have in mind one business man who had been very successful in the conduct of a business with which he had grown up and the details of which he knew thoroughly. He went into mining—bought a claim in California, had a little work done on it, and then decided to equip it with a mill. A small mill was bought, and built on insecure foundations. The question of power he decided to his own satisfaction readily enough, as a stream of water was running down the canyon—part of the time. Sometimes it was a small stream, at other times a raging torrent. Wood was abundant and in this case would have been the most economical means of obtaining power by using steam, but the business man decided upon water as a cheaper and in every way a better source of power. He had a dam built in the canyon and laid a pipe-line about 2000 ft. long, from the dam to the mill, which gave him a head at the wheel of about 50 ft. The pipe was laid so that each section projected into that next above, instead of into that below, thereby increasing friction at the joints, and worse still, causing the pipe to draw apart soon after the water was turned in, but worst of all, he had too little head (of water) to generate sufficient power to run his mill. Then a heavy rain came which quickly filled the little reservoir back of the dam and likewise filled the pipe-line and water-wheel with gravel and grit. The entire installation was useless and the self-made engineer was 'all in' financially speaking. He could have secured experienced advice for a few hundred dollars and had a plant designed to suit the conditions and thus have been able to accomplish the object he had in view. All I could say to him when he unfolded his tale of woe to me was: "I told you so before you went into this without getting proper advice."

SAMARITAN.

Bakersfield, California, September 30.

[The above is not unusual, for we have known of similar occurrences elsewhere. They may be excused, to some degree on the part of a man of small means who endeavors to make his funds go as far as possible, but there are companies with large capital available that are possessed of this same parsimonious idea of economy, making costly blunders in the engineering features of their plans, learning too late that the engineer, as well as the laborer, is 'worthy of his hire.'—EDITOR.]

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Compressors may be operated underground, though such practice is uncommon. In such cases electricity is the best source of power.

Monazite occurs in regions of crystalline rocks, particularly of granite. The greater part of the mineral is obtained by sluicing in the same manner as for gold.

Drifts and cross-cuts in the mines of Western Australia do not require much timbering, as the rock stands well enough without it. This is usually the case in desert regions.

To prevent jamming raises should be cut at as high an angle as 50 degrees, this being about the best slope angle. Raises that are vertical jam more frequently than those at 50 degrees, or near it.

The Bureau of Mines publications and advance notices of bulletins and other papers to be issued may be obtained by those interested by mailing a request for them to the Director, at Washington, D. C.

Of clays it has been known since man first made his appearance on earth that some are plastic—capable of being molded into a shape, and to retain that shape—but very little is known of why this is so. It is supposed to be due to the presence of a certain amount of colloidal material in the clay.

Old boiler tubes which are merely rusted out at the ends may generally be utilized by re-threading and used as air or water pipes. Often they are thrown away as useless, but it is rarely the case that they will not withstand a pressure of 100 lb., or even more.

In case of low water in a steam-boiler, under no circumstances turn on the feed water, and do not disturb the safety valve. Cover the fire with wet ashes, or green fuel if no ashes are at hand, and close both the fire and ash-pit doors. Let the boiler cool, leaving all outlet valves as they are. If any damage has been done it can be ascertained by inspection when the boiler has cooled.

Calcium phosphate is utilized in making fertilizer. One of the largest deposits of this mineral is found on Christmas island, off the southwest coast of Java. In 1909 there were exported by the company working the deposits 105,481 tons, which was 3616 less than the previous year. The markets for this product were in Japan, Germany, Australia, and New Zealand. The mines are owned by an English company, and the manager is an American.

There are many places where a $20 concentrate has no commercial value owing to cost of transportation and reduction charges absorbing all that the concentrate contains. The cost of chlorination varies with the character of the material under treatment, the method of treatment (Plattner or barrel process), and the magnitude of operations—a large plant being able to work at lower cost than a small one. In the Pacific Coast States the cost varies from $6 to $10 per ton of raw sulphide. The extraction should reach 90% or over.

Hammer-heads occasionally get into rock-breakers either by accident or design. In either case expensive damage usually results. To avoid this, power applied may be so gauged that although it is capable of driving the breaker while crushing the hardest rock, it will come to a stop should a hammer-head fall into the machine; the power being insufficient either to break the castings or to longer run the breaker. Another plan is to connect the breaker with a fast and loose pulley by means of wooden pegs so that in case of accident the pegs break and no strain comes on the belt or power-line.

To catch water in a mine on the levels near the surface is always good business. In some mines the water is allowed to run down shafts and winzes to the bottom, because it is more convenient to raise it from there to the surface than from some higher level. This may be so, but it is also more expensive. If the volume of water lifted from a mine be calculated by its weight, times the number of feet it is lifted, reducing it to foot-pounds, it will be seen that it runs rapidly into large power requirement. The more this can be reduced, by lessening the height of lift, the less expensive will be the cost of handling the water.

The black sand, so abundant in many streams, varies in character, with the rock through which the stream has cut its way. Where the erosion has taken place in andesites, magnetite will be abundant in the stream. If through diorite or diabase, magnetite and ilmenite are usually characteristic. If in granite, titanic iron will probably be found, as well as magnetite. Where the stream has cut through serpentine chromic-iron is likely to be abundant, though magnetite is always present in serpentine. Occasionally the sand is chiefly grains of limonite or hematite, due to the cutting of beds of these minerals, and less frequently to oxidation of pyrite.

Miners as a class are not discriminating, even in the lines of their daily work. It sometimes happens that a mine superintendent concludes that he will make a change in the explosive used, with a view to accomplishing better results at lower cost. For instance, he may decide that 70 per cent would be more effective in certain ground than the ordinary 40 per cent dynamite. The miner, having become accustomed to the use of the weaker powder, will in nearly every instance, take as much of the stronger as he has been using under similar circumstances, making no allowance for the great difference in the force of the two explosives. His acts are nearly all controlled by habit and in all things pertaining to his work he is an ultra-conservative. Customs are hard to change and while the miner may be willing to be shown, he seldom is convinced that the new way is the better one.

Special Correspondence

KALGOORLIE, WESTERN AUSTRALIA

Recent Developments.—Output.— Water Analysis. — Local Foundries for the Mines.

The Great Boulder company is putting in east and west drill-holes from the nineteenth level, north of the main shaft, to test the north end of its lease. This company has a large unexplored area at this end. The shoot of ore at the 1900-ft. level in the Lake View mine has been driven on 54 ft., sampling $11.28 per ton across the width of 7 ft. This shoot is very short, although the width and value are all right. The Star mine is opening up fairly well at the 300 and 500-ft. levels. The Kalgurli reports profitable ore at 1650 ft., while some of the outside mines are opening in a satisfactory manner. It is probable that the Lancefield will close down soon for another remodeling of the mill. The various plants that have been working on this mine, have never been successful. The ore is somewhat refractory, containing graphite and arsenic, extraction averaging 85% at a cost of $4.30 per ton treatment. The same may be said of the Gwalia Consolidated, at Wiluna. This mine has an immense lode, but the average value is said to be but $5 per ton. The crushing and treatment plant are badly situated and poorly erected, and this ore is also refractory, as it contains arsenic and antimony. Bewick, Moreing & Co. advise the erection of an experimental plant to include a roasting furnace, to treat the sulphide ore. The mine will be worked on a small scale until the scheme of treatment has been solved. For the oxidized ore, there is a 20-stamp mill, sand and vacuum filter plant. The latter has proved a serious problem in dealing with the peculiar slime produced, and many metallurgists have failed, although it may be said that the plant was badly arranged. The Golden Horse-Shoe announces its ore reserves at June 30, 1910, as 903,592 long tons, averaging $10.44 per ton. The Royal Commission on Miners' Phthisis has completed taking evidence at Kalgoorlie. Eleven hundred, out of 3000 miners, were examined by Dr. Cumpston, and also many men in the dry-crushing and roasting plants. Underground workings and conditions in the various mills were inspected. Over 2000 men have now been examined throughout the State.

The principal yields for July were as follows:

Name.	Tonnage.	Value.	Profit.	Dividend.
Associated	10,394	$75,000	$ 7,000	.....

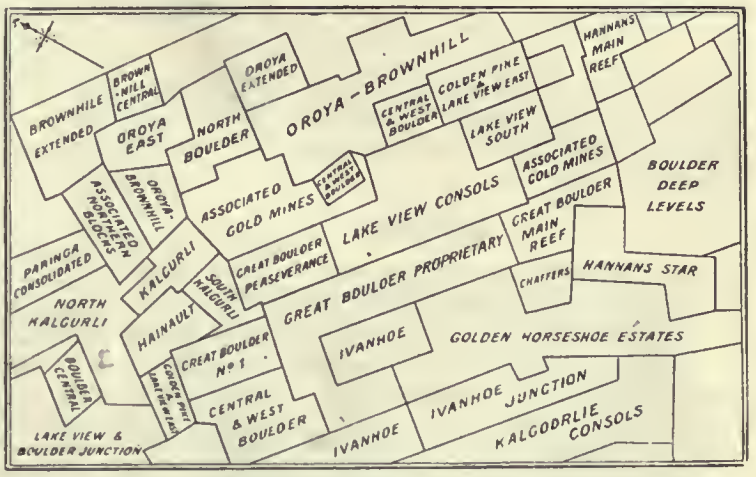
*Loss.

†From old residue.

Next month will see the Perseverance output included, as the new mill has been running for a fortnight.

The gold yield from the State in July was valued at $2,625,000, and dividends were paid amounting to $450,000. For the first six months of the current year the gold output was valued at $15,495,000 against $16,615,000 last year, while dividends paid were $2,800,000 against $3,650,000 for the same period of last year. In the imports for 1909, the sum of $785,000 is given in the custom's returns for cyanide brought to the State. This has averaged $750,000 for the last eight years. Taking the average cost at 18c. per lb., this equals 4,360,000 lb. of KCN, for the treatment of 3,105,000 tons of ore by all mills in the State, or say, 1.4 lb. per ton. In recently published returns on the various industries in Western Australia, the amount of lumber cut in the bush mills totaled 171,824,991 superficial feet, being mostly jarrah. In this district about 1100 tons of fuel are consumed daily. There were 10,212 tons of lime used in the various works, as well as 17,836,758 bricks made—fire and common. The Annual Report of the Mines Department, just published, states that the total mineral output was valued at $35,250,000; that 3,105,000 tons of ore was treated yielding $33,850,000, nearly 96% of the total output; dividends paid by gold mining companies totaled $6,750,000; the area under mining lease for all minerals was 59,245 acres; 18,336 men were employed; the average tonnage raised per man being 194 tons; 6114 men are employed on the East Coolgardie field (Kalgoorlie district), and 1,740,779 tons was treated; 395 tons of tin oxide was exported, valued at $83,000; and $1600 worth of tantalite was raised on the tinfields, where it occurs as a stibio-tantalite; 15,086 tons of copper ore was mined valued at $475,000; the Collie coalfield produced 214,302 tons of coal worth $450,000; and 176,843 oz. silver was obtained; also three tons of asbestos worth $750.



Principal Claims at Kalgoorlie.

During the month the Kalgoorlie group of mines consumed 31,046,000 gal. of water from the Water Scheme, about 1,000,000 gal. daily. The department has just published an analysis of the water:

Parts per 100,000.	
Ammonia, free	0.001
Ammonia albuminoid	0.015
Organic matter (O absorbed in 4 hr.)	0.0178
Nitrogen as nitrates	0.0065
Chlorine	16.5
Equivalent to NaCl	27.22
Hardness (°) temporary	1.75
Hardness (°) permanent	4.2

There is $155,000 being spent in a lime plant, the purpose of which is to add 5 grains CaO per gallon of H_2O to prevent the corrosion of the pipes; also in regulating tanks, and in making several alterations to the pumps.

Many mines have found that it paid to erect foundries and large shops, rather than to buy machinery and castings made in the Eastern States, at Perth, or at the foundries at Kalgoorlie. 'Spares' have been costly when buying from machinery firms, and there is no doubt that these latter have made money in the past judging by the difference in the cost of turning them out on the mines. From rock-breakers to the idlers on conveyors in the mills, ex-

tra parts have been costly. Of course, certain steel work is not attempted, but cast-iron work of all sizes and description is molded. Such things as furnace rabbles, and shoes and dies for pans, do not need any nice dressing for use. Large quantities of scrap have accumulated in years past, and still accumulate as work proceeds, and this melted down makes good castings. As for the life of the locally made spares, they seem to be equal to the imported; and even if they are not quite as good, their cheapness would make up for this deficiency. The Associated foundry casts gear wheels for ball-mills, all gear and rabbles for furnaces, pan-gears, and shoes and dies; agitator gears, conveyor idlers, pulleys of all sizes up to 5 by 20 ft., and numerous other things; the Ivanhoe turns out first-class mortars for its battery, furnace, and pan fittings, press-plates and frames, and many castings for wet-crushing plant; the Perseverance does likewise; the Lakeview & Star casts tube-mill liners, and gears for same; the Oroya Links is casting much for its battery, also plates and frames for the presses. The engineering shops on all the mines are fully equipped to turn, plane, drill, cut, saw, or thread, any casting, plate, pipe, or bar that may be required in the mills. Costs must be reduced, and if cheaper spares cannot be bought, it has been proved that it pays to make them at the mines.

LONDON

El Oro Mining & Railway Co. — Mexico Mines of El Oro. — Alvino Mines.—Rhodesia Exploration & Development.

The group of mines at El Oro, Mexico, controlled by the Exploration company is one of the most interesting on the London market. The El Oro Mining & Railway Co. was floated in 1899 to acquire the El Oro gold mine from an American company of similar name. The purchase price was £820,084 in cash and £65,988 in shares. No less than £404,661 has been provided out of revenue for the building of metallurgical plant and for other purposes. The company floated the Mexico Mines of El Oro to acquire a property on the other side of the Esperanza mine, and the Somera Gold Mining Co. to acquire property to the west. The latter was re-absorbed in 1908 in order to obviate disputes as to the ownership of certain veins. The issued capital now stands at £1,147,500 and £1,353,312 has been distributed as dividends. The report for the year ended June 30 shows that the recent remodeling of the mill was completed in February. This work involved the provision of three new tube-mills, and the dismantling of the old 100-stamp mill, so that the work is now done by the No. 2 mill containing 100 stamps, built in 1905, together with 8 tube-mills. With this rearranged plant the stamp-duty has been raised to 10½ tons, and the tube-mills give an all-slime product. During the year under review 316,138 tons was crushed, the production amounting to $2,171,774 in gold and $390,931 in silver, a total of $2,562,705 or $8.10 per ton. The amount of ore treated when both mills were working was approximately 25,000 tons per month; and after the reorganization this was raised to 30,000 tons. The costs during the year at the mine were $1,557,889 or $4.93 per ton, and it is noticeable that the new method of treatment has reduced the cost from $5.50 to $3.80 per ton during the year. There were other expenses on special ventilation work, cost of London office, and depreciation. There was also a profit on the railway and on the sale of shares in the Mexico mine. The dividend distributed absorbed £172,125 being at the rate of 15%. The report by A. F. Main, the manager, shows that development has been advanced rapidly and the reserve of ore on June 30 was 441,639 tons, averaging $8.06 in gold and 3 oz. silver per ton, as compared with 383,000 tons averaging $11.10 in gold and the same in silver a year ago. The average extraction is 94% of the gold and 78% of the silver. It will be seen that the yield is decreasing as well as the cost of treatment. Progress in the sinking of the new ventilation shaft near the Esperanza boundary has been rapid and it reached the 1000-ft. level in January. The conditions at these deep workings were thereby much improved and the exploitation of the higher-grade ore found here is proceeding actively.

The Mexico Mines of El Oro was formed in 1904. The company has a capital of £180,000 and the total dividends to date amount to £283,500. In addition £113,142 has been spent out of profits on plant and development. The metallurgical equipment consists of 40 stamps, 6 tube-mills, cyanide plant, and concentrators. During the year ended June 30, 136,372 tons of ore was crushed by the stamps. The sulphide ore recovered on the concentrators used to be sold to smelters, and during the year 253 tons, worth $49,693, was disposed of in this way. More recently the concentrate has been treated on the spot, by cyanide, and 607 tons has yielded bullion worth $60,749. It is found that by cyaniding, the extraction from the concentrate is 97½% of the gold and 91½% of the silver, and the profits are greater than when selling to smelters. The total extraction was $1,026,923 in gold and $365,413 in silver, a total of $1,392,336. The costs at the mine were $638,786. The profit and loss account shows an income of £294,694 and an expenditure of £139,373, leaving a profit of £154,990. Out of this £7893 has been spent in capital account, £8000 is allowed for depreciation, and £9000 allocated to income tax. The dividend distributed was £126,000 being 14s. per £1 share. A. F. Main, the manager, estimates the reserve on June 30, at 283,735 tons containing 9.57 dwt. gold and 5.9 oz. silver.

The Avino Mines was originally formed in 1899 by F. L. Gardner to acquire a mine at Avino, Durango, Mexico, and reconstructed in 1903 and 1909. The ore is complex containing copper, lead, gold, and silver, and many mining engineers and metallurgists have without success attempted to devise suitable methods of mining and concentrating. In fact large sums of money have been spent on a plant that has failed to work. The ore deposit is erratic and is difficult to follow and estimate. Among the engineers who have attempted the solution of the problem are A. A. Blow and Ralph Nichols. On the reconstruction in March, 1909, R. H. Jeffrey was appointed manager, and Edward Hooper was elected to the board. A method of treatment of the ore, devised by Henry E. Wood, of Denver, was adopted on trial, and is still subject of experiment. The report for the period from reconstruction to June 30 shows that of the ore, sorted by hand, and the best parts sold to smelters: 43,350 tons was mined, 18,094 tons shipped, 6420 reserved for further treatment, and 17,937 tons rejected as waste. The ore shipped contained 993 oz. gold, 261,000 oz. silver, and 413 metric tons of copper. The total value was £49,023, and the cost of treatment and freight was £28,172. The mining cost was £13,457, and other costs £6300. The net profit on the year's operations was £1115. The issued capital of the company is £56,440 divided into 978,429 ordinary shares of 1s. each and 300,750 priority shares of equal denomination, but on which only 6d. is paid up. Mr. Jeffrey reports that considerable improvements have been made so as to put the workings in good order. The reserve blocked out on June 30 was 57,525 tons and of partly developed ore 33,560 tons. In addition 16,400 tons is at surface awaiting treatment. The average content of the ore is estimated at ½ dwt. gold, 10 oz. silver, and 1¾% copper. The future of the company depends on the system of concentration and extraction now being tested. Details of the process and its results will be available before long.

An important consolidation of Rhodesia companies has this week been effected by the absorption by the Rhodesian Exploration & Development, the chairman of which is Hans Sauer, with its four subsidiaries, the Rhodesian Banket, Etna Development, Rhodesian Abercorn Shamva, and the Gold Schists of Rhodesia. The amalgamation is a matter of directorial policy, and it enables Abe Bailey to take an interest in the group and to guarantee the issue of new shares. The capital of the Rhodesia Exploration & Development has been increased from £450,000 to £2,000,000. Shareholders in Rhodesian Banket will receive 7 new shares for every 10, in the Etna Development 1 for every 2, in the Rhodesian Abercorn Shamva 4 for every 5, and in the Gold Schists 1 for every 2. No new shares are allotted in respect to the shares in these companies held by

the Rhodesian Exploration & Development. It may be noted here that the Shamva and Gold Schist companies have only recently been formed. The Rhodesia Exploration & Development is a profit-earning company and has large cash assets. The four other companies have also large sums of working capital. Further capital is to be raised by issuing 250,000 new shares at £2 5s. each, which have been guaranteed by Abe Bailey. The total working capital and realizable resources will be £1,600,000. The plan has been approved by the shareholders of the various companies.

NEW YORK

Political Influence on the Market. — Coppers. — Texas Oil Company.

The political situation has kept the stock market marking time. There has been a much better tone prevailing, slightly higher prices, and a moderate increase in the volume of trading, but on the whole business has been subordinate to politics and the Saratoga convention. So far as the market for mining securities is concerned the crusade started this week by the Federal authorities to clean up the New York Curb is by far the most important event which has occurred for months. The offices of B. H. Scheftels & Co., in New York, Chicago, Boston, Milwaukee, and other cities, were closed as bucket shops this week, the heads of the New York house and the managers of the various branch offices held for frauduient use of the mails. The ruling spirit in the house of B. H. Scheftels & Co. was George Graham Rice, whose publicity campaigns have from time to time attracted the attention of the whole country, and whose career has been thoroughly aired repeatedly. Since the establishment of the house of Scheftels, Rice has been carrying on spectacular campaigns in Ely Central, Jumbo Extension, Rawhide Coalition, Rawhide Queen, and other issues. To sell these issues fortunes have been spent in advertising and it has been repeatedly stated that the house was doing more business than any three houses in the Street including the members of the Stock Exchange. The end was a natural one and wholly inevitable. The operations of Rice, while conducted on a large scale were not in and of themselves of so great importance as was the effect upon the general market. The New York Curb has become the natural outlet for the country's mining securities, and if properly protected, will quickly become a market second only in importance to the New York Stock Exchange. The unhindered action of the Curb bucket shops has, however, in effect, prevented the distribution of securities on the Curb and the demoralization of the Curb market has been complete for some months. If the Federal crusade is made complete and effective a rapid and extremely beneficial improvement may be confidently expected. The various issues manipulated by Scheftels & Co. broke sharply after the raid by the police, who arrested the principal officials and confiscated the books and locked the office doors. A special meeting of the Braden Copper Co. has been called for October 8, to approve the issuance of a $2,000,000 convertible bond issue. One-half of the issue is to be sold at once and the proceeds to be immediately expended in the completion of the water-power plant and smelter, and the enlargement of the concentrator, the balance of the issue will be held to build a leaching plant and to provide working capital when necessary. The bonds will be offered at par, they are subject to the present outstanding issue, are callable at $110 subject to the right of the holder to convert them into common stock. The first annual report of the Ray Consolidated Copper Co. bears out the prediction that this property is to become another Utah. The developed ores including those of the Gila, recently absorbed, are calculated at 75,000,000 tons. Operations are to begin during the early part of the coming year on a basis of an annual output of more than 80,000,000 lb. of copper. Chino has been the market leader of the Coppers during the past week. The shares reached $19, a record high mark. The National Mining Exploration Co., with properties in Gila, Pinal, and Graham counties, Arizona, which has been traded in Boston to some extent, has filed a voluntary petition in bankruptcy, giving liabilities at $393,050; assets, $23,807.

The report of the Texas Oil Co., the great oil concern which has been built up by John W. Gates since his retirement from Wall Street, made to the listing committee of the New York Stock Exchange, shows gross earnings for the year last past of practically $10,000,000; oil on hand, crude, refined, and in process of manufacture to the amount of $6,557,242; other assets are pipe-lines, $9,188,000; tank steamers, tank cars, terminals and distributing stations, $5,235,000; refineries, $4,045,000; which with other smaller items brings the total to $32,901,866. Mr. Gates' company has complete control of the new field at Caddo, Louisiana, and is a large factor in the Oklahoma and Kansas oilfields.

ELY, NEVADA

Nevada Consolidated Curtailment.—Giroux.— Ely Calumet. — Boston Ely-Ely Consolidated.

On the first of September an order went into effect at the Steptoe plant to shut down the concentrator on Sundays, and in addition to this one-half of the big plant is down all of the time, which has materially decreased the tonnage of ore treated. In fact, during the entire month of September the daily output of ore from the mines will not average more than 5500 tons, as against an average

Drilling in an Ely Mine.

of between 9000 and 10,000 tons during July and August. It was understood by orders issued from the New York office of the company that the reduction would not amount to more than 15%, but at the present time only about 50% of the ore formerly treated is going through the concentrator. But notwithstanding this fact the outrun of copper will equal, if not surpass, all former months. This is due to the fact that the capacity of the concentrator is far in excess of that of the furnaces, and consequently there was a large supply of calcined ore and concentrate on hand when the order was made for reduction. However, the smelter is now rapidly gaining on the concentrator. During the present week five furnaces have been in steady operation, and the reserves are being drawn upon heavily. The Nevada Consolidated company is opening its new Liberty pit with a rush, and the chances now seem probable that it will be in a condition for production by the first of the new year. Only one steam-shovel is being employed at the present time, but another will soon be put to work. It is

also probable that the Veteran mine, which has been closed down for more than a year, owing to labor troubles, will again be opened. The Nevada Consolidated will need the dry ores from the underground working of the Veteran during the winter months when the ores from the pits are frozen, and therefore difficult to handle.

All surface work at the Giroux property is progressing satisfactorily. The steel engine and boiler rooms are rapidly assuming proportions and the steel head-frame over the big Giroux shaft will soon follow. The buildings will be completed before cold weather commences, after which the cross-cut from the 1200-ft. level will be started for the old Alpha workings, which will be reached in about two months' time. While this is going on the big pumps will be put into position on the 1200-ft. level. It has been announced by the management of the Giroux company that its plant, when erected, will be at or near the mines, but no intimation has been made as to when construction work will be commenced, though it is reasonably certain that nothing along these lines will be undertaken before spring. The company has had four churn-drills at work all summer prospecting new territory, and it is understood that the results have been entirely satisfactory.

S. C. Constant, of New York, arrived in the district Saturday last and has been inspecting the Ely Calumet property, with a view to taking over a controlling interest in the company from A. Meyers, Thomas Rockhill, and G. L. (Tex) Rickard. The property has been operated under lessees during the past few months, who have brought in some fine showings of ore. The company has done nothing in the way of development for some time past. It is thought that a change of management will be beneficial to the stockholders. E. C. Chase, a mining engineer of Denver, has been spending some time at the Boston Ely, giving the property a careful examination. It is said that his report will be favorable to the further exploitation of the property by diamond-drill operations from the 1200-ft. level, as this is undoubtedly the cheapest and quickest way to prospect the ore. The Ely Consolidated is installing a pumping plant on its Zack mine near the Star Pointer shaft of the Nevada Consolidated. As soon as the pump is in operation the main shaft will be sunk as rapidly as possible, to the depth of several hundred feet during the present winter, and a large tonnage of ore blocked out below water-level.

BUTTE, MONTANA

September Production.—Heinze Properties.—St. Lawrence Closed. — Butte & Superior to Issue Bonds.—Tuolumne-North Butte Suit.

The Butte mining companies produced approximately 23,000,000 lb. of copper in September against 24,762,800 in August, the September production being between 4,000,000 and 5,000,000 lb. below the normal average for the district. The different companies contributed to the totals as follows:

	Monthly Ore Tonnage.	Monthly Lb. Copper.
Boston & Montana	90,000	6,300,000
Anaconda	126,000	7,812,000
Butte & Boston	15,000	930,000
Washoe	12,000	732,000
Parrot	3,750	236,250
Trenton	12,900	799,800
North Butte	30,000	1,890,000
Butte Coalition	37,500	2,550,000
Original	15,000	960,000
Tuolumne	3,000	210,000
Butte Ballaklava	900	90,000
East Butte	6,000	480,000
Totals	352,050	22,990,050

On his return from Idaho after an inspection of his Stewart property, F. Augustus Heinze spent several hours in this city before leaving for New York to take the steamer for Paris where he goes to complete the arrangements for the sale of Ohio bonds. "I am highly pleased with the conditions existing at the Stewart mine," he said on his return to this city. "The Stewart is earning gross about $35,000 and $15,000 net per month on 250 tons of ore shipped per day." When asked about operations at the Colorado mine of the Davis-Daly company, Mr. Heinze replied: "While here I have devoted considerable of my time to a thorough inspection of the mine and am well satisfied with conditions. The 1700-ft. level is being opened and the cross-cut from the Colorado to the Hesperus is still being extended, though nothing of value has yet been found. However, the 1700-ft. level is showing up better than the 1500 did, though not so well as the 1400. The vein is narrower, the width being from two to five feet, but the value is about the same as on the 1400." Those who expected to learn something concerning the sale of the Hypocka company to Thomas F. Cole for $25,000 through the examination of F. Augustus Heinze were greatly disappointed, as the citation calling Mr. Heinze into court to tell about the transaction, was dismissed.

The St. Lawrence mine of the original Anaconda group has been closed down and it is not expected active mining operations will be resumed again for at least two months. This is due to the big ore-house alongside the mine containing about 3500 tons of ore sliding down the hill and being utterly demolished. The ore-house was twenty years old and the question of constructing a new one was under consideration. Advantage of the enforced shut-down of the St. Lawrence will afford an opportunity of re-timbering the shaft and this work will be commenced at once. This close down, it is stated, will not mean any decrease in the output of the original Anaconda group as the production of the other mines will be increased to about 1000 tons a day, which was the output of the St. Lawrence. Plans are already being prepared for the erection of a new ore-house of a substantial and modern character and work will be commenced just as soon as the plans are ready. The work of preparing a foundation has been commenced and the intention is that not any time shall be lost in restoring the building. All the men employed in the St. Lawrence will be divided among other mines.

The Butte & Superior continues to make regular shipments to the Basin concentrator and the directors believe they have found a way out of the financial difficulty which has been hanging about the company for several months. It has been decided to issue $1,000,000 6% semi-annual refunding and improvement bonds bearing date September 20, 1910, to mature September 20, 1920. These bonds are to be first offered to stockholders and are convertible into the stock of the company at par, which is $10 per share, during the five-year period from their date of issue to September 20, 1915. It is provided that there shall be paid $125,000 per annum into a sinking fund on or before September 20, of the years 1913 to 1920 inclusive. It is also stated that the first call for retirement of the bonds shall not occur prior to September 20, 1915. Stockholders have a prior right of subscription to the bonds at par, pro rata as to their holdings of record up to and including October 20, 1910, after which time all bonds remaining unsold over and above the pro rata subscription by stockholders, will be allotted to stockholders who may have heretofore tendered a subscription in excess of their pro rata share. If there are still bonds unsold the same will be offered to the general public. The bonds will be issued in denominations of $50 and multiples thereof. The stockholders are now receiving blanks on which to make application for the bonds. The money derived from the bonds will be used in refunding and improvement of the property, it being the intention under the latter head to construct a mill on the company's property to treat the ore.

The Butte-Ballaklava company is doing a large amount of development outside of the ground in dispute and is shipping about 150 tons of ore per day to the East Butte smelter. The Tuolumne Copper Mining Co. has filed its answer to the North Butte Mining Co. in the suit brought to recover ground alleged by the latter to be its property. The answer makes a general denial of the claims set forth by the

North Butte company and charges that the North Butte has extracted large quantities of ore from the eastern portion of the Tuolumne and from the so-called compromise strip, belonging to the Tuolumne company. The Tuolumne asks for an accounting of the ore alleged to have been taken from the Tuolumne property by the North Butte and in addition an injunction is asked against further extraction of ore from the property in question. The answer declares that a great portion of the ore which has been extracted by the Tuolumne company is from the compromise strip and denies that the North Butte has a three-eighths interest in this strip or any interest at all and claims that the deed obtained by John G. Morony for the North Butte company does not convey any interest whatever. It is further alleged in the answer that the entire interest in the compromise strip has been claimed and possessed by the Tuolumne company for many years and that the company has paid all taxes on it and spent large amounts in developing it and making it valuable. It is stated that neither Mr. Morony or his grantor has contributed anything toward development or any other expenses and that it was only within the last year when the strip was found to be valuable that any claim was made by the North Butte to a small interest in the property. It is also set up that the North Butte company and its grantors are barred by laches from making any claim to any portion of the compromise strip. It is alleged that the Tuolumne is an older location than the Jessie, that the ore in the compromise strip belongs to a vein apexing in the compromise strip and that the apex has been clearly developed and that the Tuolumne claim has the ore in this vein below the point near the 400-ft. level, where it is probably joined by the Jessie vein. The answer further states that the development has not been made on the extreme western end of the Tuolumne and Jessie lodes to the extent necessary to determine whether or not the great orebodies belonged to the Jessie or the Tuolumne, but declares that if development shows that the ore belongs to the Tuolumne it will make claim against the North Butte for the same.

DENVER, COLORADO

Activity at Leadville.—Demand for Silicious Ores.

The recent discovery, or rather recognition, of large reserves of zinc carbonate in the abandoned workings of several of the older mines of Leadville, has had quite an astonishing effect upon the general state of affairs in that famous camp, and recalls the circumstances that led up to the recognition of the wealth of the district in lead carbonates in 1876-1877. Leadville lies in California gulch, and the latter, in 1861, was a booming gold miner's 'Happy Valley,' which, for several years, until the cream had been well skimmed off, turned out from two to three million dollars worth of gold dust during the short placer mining season possible at the altitude, which is high above sea-level. But its miners were always more or less troubled in their operations by the occurrence in the sluice boxes of a heavy gray sand, that would lag behind and fill up the riffles, adding greatly to the difficulties of cleaning up. No one seemed to know what it was, and all were too busy to investigate. A dozen years later, however, when the locality had faded to the status of a mere memory, the story of this material drifted accidentally into the ears of a certain Mr. Wood, of Detroit, who, having had considerable to do with lead carbonates in Nevada, and being of an investigating turn of mind, was moved to proceed at once to the almost forgotten camp and to verify the story and examine the slopes of the ravine. The result was the location of outcrops of the great silver-lead deposits that in a few months made the locality famous. And now it is being proved that for many years past, in a number of the mines, miles of drifts have been run in, or alongside of, or above, or below large bodies of zinc carbonate, under the impression that the stuff was merely an unusually heavy kind of porphyry. It is a little too early yet to say how much of this very desirable ore is immediately available for extraction, but some careful investigations have been made in the properties of the Western Mining Co., which include the Wolftone, Maid of Erin, Adams, and other well known claims in the vicinity, by a representative of one of the large Mississippi Valley smelters, and his conclusion is that a production of 300 to 500 tons per day is available with little effort from this ground, with the probability that such an output can be maintained for several years before the bodies already in sight will be exhausted. Since this news was made public there has been a wonderful amount of poking around in the old levels and drifts of the mines of Carbonate and Iron hills, and a lively demand for leases on many partly or wholly abandoned claims. Some of the big waste dumps are also being examined with encouragement or success. Considerable zinc silicate is being detected along with the carbonate, or in masses by itself. In some of the bodies of both kinds the ore is remarkably pure and clean, so that a product closely approximating 50% of metal can be produced in quantity. In others there is an uncomfortably large iron content, which will materially lower its commercial value.

North American Smelter, Golden, Colorado.

In still others there is an admixture of lead carbonate or sulphide, which must be separated before the material can be marketed. But, taking all these matters into consideration, and making due allowances for the inevitable exaggerations that accompany all new discoveries, there is yet good ground for believing that the output of zinc ore from Leadville during 1911 will exceed anticipated results. It is considered remarkable that this material has remained unrecognized for so many years, during which the principal underground workings of the larger mines have been examined and studied again and again by well known geologists and mineralogists. And it is now recalled that in the early eighties, when the great bodies of ferruginous lead ore were being taken out, a considerable percentage of a heavy gray-white mineral of a very objectionable character was often met with, at the time, was rather hastily considered to be barite by the smelters, but it is now known that this mineral is exceedingly rare, if not entirely absent from the Leadville ores, and the inference is that it was zinc. The incident illustrates the easy going smelting methods in vogue twenty years ago. But in those days, when smelting charges ranged from $20 to $30 per ton on oxidized ore, and no one thought of demanding anything for the gold content of their ores, the margin of profit was large enough to cause such matters to be overlooked.

In their distress for silica the smelters of the State have been cutting the working charge on Cripple Creek ore for some time past, and drawing it away from the mills there, and at Florence and Colorado City. The latter have now been compelled to follow suit, to maintain their supply. Rates are now down to $6.50 per ton on $40 ore, and $7 on $40 to $60 material. These are remarkably good figures for the miner and are still profitable for the mills. It will result in a decreased flow of the highly silicious mineral of the district to the smelters.

General Mining News

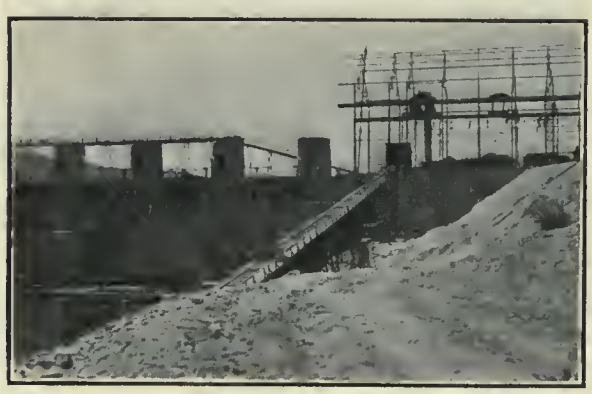
ALASKA

The Alaska-Treasure gold mine on Douglas island is undergoing vigorous development, in direct charge of Theodore Harper. In driving the deep cross-cut, now in 2700 ft., the intermediate lode was bisected last month, opening an orebody 50 ft. wide which samples $4 per ton. The main Treasure lode will probably be intersected by driving 1000 ft. farther. Development is to be continued during the fall and winter, and a stamp-mill of 1000 tons daily capacity is to be erected at the property next year.——Pearse, Kingston & Browne, of London and New York, consulting engineers for the Alaska-Perseverance Gold Mining Co., of Juneau, have recently declined to continue longer in that capacity in consequence of serious differences on questions of policy as to the methods of handling the property.

ARIZONA

GILA COUNTY

(Special Correspondence).—Three churn-drills are in operation at the Inspiration property on the Pinto Colorado and Apex claims. There are 200 men employed underground and about 30 working faces are being constantly pushed forward. The main extraction adit the mouth of which is in Keystone gulch and which runs into the Joe Bush shaft is 2200 ft. in length and has been driven in exactly four months. It was driven from both ends and two 3-in. drills were used in each face.——The Miami company is working in the neighborhood of 100 men underground and 300 on the surface. Three drills are developing the property further to the west and attempting to find the limit of the orebody.



Miami Mill Under Construction.

Miami, September 29.

MOHAVE COUNTY

The first section of the Golconda mill, with a capacity of 40 tons per day, has been completed and trial runs made during the past week have proved highly satisfactory. The plant is a standard concentrating mill with crushers, rolls, jigs, and Wilfley tables. John Boyle, the manager, estimates the total of the milling ore already broken in the stopes and on the dumps at 30,000 tons worth about $8 per ton. Work has been started on the second section of the mill and 80 tons per day will be handled by November 1. In the meantime shipping is continuing steadily at the rate of 600 tons of 48% zinc ore per month. In the Tub mine, owned by Mr. Boyle personally, development has been stopped pending the erection of a large mill for the treatment of the Tub ore alone.——Driving east from shaft No. 2 on the 500-ft. level of the Gold Road mine has disclosed still another ore-shoot with about seven feet of good milling ore.——The Tom Reed mine paid its second dividend of 3c. per share several days ago. The 10 stamps are crushing about 45 tons per day, averaging a little over $40 per ton. The stamps of the old mill are to be moved up to the new and will be put into operation as soon as possible.——At the Ruth mine the new shaft at a depth of 30 ft. is in better ore than that found in the old at a similar depth. Since cyanide tests made by Daniel Bosqui, mill superintendent of the Gold Road, proved an extraction of only 58%, all idea of an extraction by percolation alone has been abandoned, and thorough mill tests of the Ruth ore are now being made by the Young Construction Co. of Los Angeles. A plant similar to that of the Gold Road will probably be erected.

CALIFORNIA

CALAVERAS COUNTY

A shoot of ore has been opened by T. Porteous in the Old Cheek mine near West Point at a depth of 70 ft. and five tons of material has been placed on the dump.——The Haley brothers have driven a drift on the vein at their claims in Mott gulch and are storing $50 ore for shipment.——The shaft at the South Australia mine is down about 70 ft. in ore which pans well.——It is reported that operations are to be resumed at the Moser mine in the Mokelumne Hill district.——The Caloro Mining Co. is developing a group of gold-copper veins just south of Campo Seco. Several shafts and adits have been driven in ore which runs from a few dollars to upward of $200 per ton. It is proposed to ship the ore now being mined. W. H. McClintock is manager.

MARIPOSA COUNTY

A break in the flume at the Hasloe mine has stopped work for a few days till repairs can be made.——The bond which P. G. Gow held on the Champion property has expired and the mine has been closed down.——A good body of milling ore is being opened at the old San Domingo mine on Bear creek five miles from Briceburg. R. L. Mann is superintendent.——A syndicate of Eastern men has been formed to work the McCall and Tucker placer ground a mile and a half above Merced Falls, and machinery has been shipped to the property to raise water for the sluices.

NEVADA COUNTY

The office buildings at the Providence mine which is one of the Champion Mines Co.'s holdings were destroyed by fire. The flames were fortunately checked before the mill buildings on the property were reached so the damage was not serious.——During the summer 1200 ft. of flume has been constructed and 800 ft. of pipe laid at the Andy Fitz mine near Moores Flat. The new compressor has been set on its foundation and active mining commenced.

PLUMAS COUNTY

The Gold Mountain Hydraulic Mining & Dredging Co., under the supervision of George W. Flagg, is building a large dam near its property on Willow creek and preparing for extensive operations in the spring.——Preparations are under way for the unwatering of the Franklin shaft at Nelson Point. The shaft is down 200 ft. and was sunk about thirty years ago when the operators were forced to abandon the work on account of an excessive flow of water. It is thought that a small amount of work will open the channel.

SHASTA COUNTY

The furnaces at the Balaklala plant of the First National Copper Co., at Coram, have been blown in and the Cottrell plant is successfully handling the smoke. The ore-bins at the plant are full of ore but as soon as this can be lowered operations will be started at the mine and the tramway put in motion.

SIERRA COUNTY

The Empire mine in Gold valley has been closed for the winter as the cost of hauling in supplies during the wet season is excessive.——Charles R. Thompson has let a contract to move some of the buildings at the Mountaineer mine to the Colombo near Sierra City which he is operating under bond.——Horace Cleland and S. Chastine have opened a streak of pay-gravel at their claims near Poker flat.

SISKIYOU COUNTY

(Special Correspondence).—The Aiken-Graham Co. of San Francisco has installed a steam shovel on the Dagget placers at Oak Bar, on the Klamath river, and will commence operations within a few days. The ground has been

thoroughly tested and there are several thousand acres of land containing auriferous gravel.——The Mott brothers have completed a wing dam on their property on the Klamath and have commenced pumping. Considerable high-grade gravel has been opened.——At the Highland mine the recently organized company is arranging for vigorous development.——McDonald, White & Armstrong have uncovered a vein of gold-copper ore two miles below Oak Bar.

Yreka, October 4.

TUOLUMNE COUNTY

(Special Correspondence).—The Spring Gulch mine, situated four miles south of Tuolumne, has been bonded to Colorado capitalists. Tools and all necessary supplies are being hauled to the property and active operations will be commenced at once.——Development is in progress at the Rising Sun mine, at Arastraville, and extraction of ore has begun. The tunnel is undergoing repairs and will be started in the near future.——The management of the Jumper mine has purchased several new machine-drills and is making preparations for carrying on operations on a much larger scale. More than 50 men are at present on the pay-roll, but most of these are employed in surface work.——Operations have been temporarily suspended at the Maddox mine, near Confidence. It is said negotiations are in progress for the sale of the property, and it is understood that should this fail a larger mill will be installed by the owner, John Frey, and the mine then worked on a more extensive scale.——An underground hoist and an air-compressor have been installed at the Duffield, near Arastraville, and the work of erecting a 10-stamp mill is progressing rapidly.——Repairs and improvements are being made in the Harvard mill, among which is the putting in of concrete mortar blocks. During the progress of this work a number of stamps are of necessity hung up, only 40 of the 60 now being in operation.——It is reported that operations will probably be resumed at the Santa Ysabel.——Work will be resumed at the Donella, above Arastraville, in the near future.——At the Toledo mine, west of the Rawhide, a small crew of men is employed in development.——The Green Horn and One Chance quartz claims near Rawhide have been bonded to W. T. Watson who will immediately begin the development of the properties.——It is reported that development work will shortly be resumed at the Mariana copper mine, near Chinese, by A. Elliott of Modesto.——The Ruby Hill Mining Co. is preparing to resume work at its gravel property in the Jupiter district. A new shaft will be sunk, the hoist to be operated by steam power.——Articles of incorporation of the New Providence Gold Mining Co. and the East Belt Gold Mining Co. have been filed in this county. The capital stock of the former is $250,000, the directors being S. P. Hammond, C. S. Wong, J. F. Bluett, C. Bluett, and J. D. Hammond; that of the latter $100,000, the same men constituting the directorate, excepting C. S. Wong, whose place is taken by William Bluett.

Tuolumne, September 3.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A streak of ore 3 to 5 in. wide has been uncovered on the Seven-Thirty vein that assays 2106 oz. silver and 1.10 oz. gold per ton.——Charles Okiun, owner of the Scott mine on Republican mountain, has resumed development. Shipments of galena containing 65% lead and 40 oz. silver per ton have been started.——The Jewell mill at Silver Plume has been sold to the Little Gilpin Mining Co. and the plant is to be dismantled. The machinery will be shipped to the property of the company in Gilpin county.——Work was put under way last week on the McKinley property on Lincoln mountain. S. D. Tibbetts, of Denver, is manager.——James Beshears, owning the Esconado and Rex properties, returned this week from Colorado Springs. He states that a working fund of $32,000 is to be provided.——Construction on the new mill for the Santiago Mining, Milling & Tunnel Co. was started this week. The sampling department will be completed first. Wm. Rogers is manager.

Georgetown, September 30.

GILPIN COUNTY

(Special Correspondence).—The Leidinger property in the Vermillion district, has been entered among the list of shippers. The last shipment netted 5 oz. gold per ton.——A new Norwalk compressor was received at the Seemann adit last week. It is announced that this adit will be continued for 3000 ft. H. K. Seemann, of Denver, is manager.——New machinery has been installed at the London mine at Twelvemile. Leod & O'Connell are operators.——The Montana Hill Tunnel Co. has awarded a contract to drive an adit to intersect the series of veins.——The water in the Gunnell mine is lowering at the rate of six inches per day. A number of lessees are at work in the upper levels and heavy shipments are going out.

Central City, October 1.

IDAHO

SHOSHONE COUNTY

Reports from Mullan state that the drift on the Missoula Copper Co.'s property is now in 40 ft. and that a foot of shipping ore has been exposed the entire distance. The rest of the ore opened is high-grade copper of milling character. The adit has not touched either wall so far and the width of the ore-shoot is uncertain. The Missoula lies in the immediate vicinity of several prominent copper mines, including the Snowstorm, the Snowshoe, the Lucky Calumet, the National Copper, and the Independent, through whose workings the discovery on the Missoula was made. R. C. Vanderfoot, formerly expert for Finch & Campbell, of Spokane, says that the recent find is important, adding: "The whole face now is in ore that will average between 6 and 7% in copper, with a still greater percentage of lead. The copper occurs in the form of oxide and chalcopyrite and the lead as galena."——Lead-silver ore reserves of an estimated value of more than $5,000,000 are reported to be in sight on the Marsh property at Burke, which will enter the list of producers within 60 days. The mine is owned chiefly by business men of Butte, Missoula, and Spokane. Five feet of ore, 50% of which is of a shipping grade, averaging 60% lead and 54 oz. silver per ton, has been exposed on the present loweat level, which is above the levels at which the Hecla and Tiger-Poorman mines showed their worth. The rest of the vein on the Marsh property is concentrating ore, averaging 15% lead and about 13 oz. silver.

MISSOURI

JASPER COUNTY

(Special Correspondence).—There is quite a large amount of prospecting and development in the northern part of the county. On the Weaver land near Neck City drilling is being done on an 80-acre lease and at a depth of 40 ft. encouraging prospects have been struck. This territory is near the Quick Seven tract, which has been developed during the past two years and is still practically virgin land. The grade of ore in this vicinity is among the best ever mined in this entire district, averaging over 60%, and commanding above the market basis price. Some of the ore in the Quick Seven mines contains 64% blende.——The Quick Seven Co. has completed a shaft to the ore-level which was started some time ago and abandoned at 40 ft. Drilling near it has shown the tendency of the ore in that direction. The shaft will be connected to the mill by a tramway and ore will be taken from both workings. The output for September from this mine averaged 20 tons per day.——The fourth mill on the Quick Seven lease haa been built with the completion of the T. S. & J. plant, a mill moved from the Glass lease in the Webb City district. The development at this mine has been quite extensive and a large boulder pile has accumulated awaiting the erection of a plant. The workings here are in comparatively hard ground, requiring little timbering.——To the south of this camp the Oronogo Circle Mining Co. is preparing to take up a large stope over the entire workings, a move which will make the drifts over 100 ft. high. They are already between 50 and 60 ft. in height. This company has been experimenting with the core-drill in the place of the regular churn-drill and has proved it very satisfactory as show-

ing the character of the formation better than the old method. Cores from 2 to 3 ft. long were removed. The core-drill was set up in the old drifts which were 235 ft. below the surface and the holes were sunk to below the 300-ft. point.

Joplin, October 1.

NEWTON COUNTY

(Special Correspondence).—A number of properties are busy in the Spring City camp, some with additional prospecting and others with the preliminary work attending the reopening of closed mines. The Amarillo company which recently took over the old Microbe mine has started drilling in the western part of the lease. Development hitherto has been confined to the eastern part of the land. The ground has been drained to the 116-ft. level and a 4-ft. stope will be taken up over the entire workings. There is a small 100-ton mill on the lease.——The Sunrise company has begun the drilling of a series of holes west of the present workings to determine the extent of the ore. In addition to this prospect work the U. G. Wilson company is sinking a new shaft on the south side of the lease and prospects are so encouraging that it is probable that the mill will be removed to the new shaft. Ore has also been developed in drill-holes on the western part of the lease.——The Mary E. mine has made a good record as a producer recently under the management of C. C. Playter. Drifts are being run to the south and west. The shaft when sunk, opened ore on all sides in a 50-ft. face. Only the lower 25 ft. is worked as the upper 25 was not so rich. Operations are conducted at the 120-ft. level. The company is now beginning to take up a 5-ft. stope over the entire workings.

Spring City, September 30.

NEVADA

ESMERALDA COUNTY

The report of the engineers on the Jumbo Extension ground, at Goldfield, estimates that there is approximately $3,000,000 worth of ore available in the underground workings.——Development on the 300-ft. level of Wheeler lease on the Spearhead ground continues to open pay ore and a second lease has been granted on a part of the property.——Steady development is continued at the Combination Fraction though no new ore has been opened.

LANDER COUNTY

(Special Correspondence).—The new mill of the Austin-Manhattan Co. is rapidly nearing completion, the dryer having been completed and everything placed in readiness for the installation of the other machinery. The Ophir shaft has been retimbered for 175 ft. The Jack Pot shaft is going down rapidly and is now about 50 ft. below the 200-ft. level. The east cross-cut from this point is out 260 ft. and is being driven to intersect the Silver Chamber vein and other orebodies lying between the Jack Pot and Silver Chamber shoots. The company is shipping in large quantities of fuel and supplies and the coming winter promises to be a busy one. The mill will probably be in operation this winter.

Austin, September 30.

NYE COUNTY

(Special Correspondence).—The Indian group of claims, which is being operated under lease by R. E. Clapp and A. K. Ishmael, is situated on the southwest slope of the Funeral range about two miles below Keane springs and seventeen miles from Rhyolite. In a gulch heading at the summit of the range a dam has been placed which retains sufficient water to supply the camp and the mill which at present consists of a 1350-lb. Nissen stamp with inside amalgamation and a New Woodbury table. Power for both pumps and mill is furnished by gasoline engines and it is the intention of the lessees to add another stamp to the plant in the near future. The mill is of substantial construction, all the foundations being of concrete. The stamp has a fall of 6 in. dropping 102 times per minute. The principal vein is on a contact between a schist and a silicious limestone, the former being the hanging wall. It is comparatively flat and averages about three feet in width, the pay-streak varying between 12 and 15 in. The richest part of the vein is near the hanging wall and shows considerable free gold although it is accompanied by a streak of galena. It is developed by a number of drifts and the ore from the stopes is trammed in cars to the mill where it passes over a grizzly to a crusher and then to the ore-bin. The ore is said to mill $16 to $18 per ton. A fairly complete assay laboratory has been installed a little above the mill and the plant seems to be a complete success although the costs are high on account of the limited capacity.——A. S. Burns who has a lease on the Hartford property about two miles west of the Indian group near the base of the range is stacking ore which will average about $40 per ton and will pack it on burros to the Indian mill for treatment.

Rhyolite, October 1.

The Tonopah Mining Co. has declared the regular 25c. per share with an extra one of 15c. per share, payable October 21. This will distribute $400,000 among the stockholders and make the total for the year $1,500,000. After the payment there will still be over $1,000,000 in the treasury of the company.——The last raise on the ground of the Round Mountain Mining Co. at Round Mountain has opened a flat vein which assays $8 to $14 per ton and adds a large amount of ore to the company's ground outside the territory in dispute.

OREGON

JACKSON COUNTY

(Special Correspondence).—The Pleasant Creek Gold Mining Co. has had a preliminary examination of its ground by Otto L. Haese. The company owns, or controls, 700 acres of placer ground south of Battle mountain. The mines are reached from Woodville on the Southern Pacific by a fair road of 12 miles. Wood and water for working the ground are abundant. The gravels extend from Battle mountain to the north, to the former town of Wimer on the south, and are limited by the mountain spurs east and west. The bedrock is decomposed granite that forms natural riffles. The overburden of sandy clay averages 5 ft. and carries 10 to 30c. per cu. yd. The gravel attains depths of 5 to 20 ft. with an average of 8 ft., and carries 35c. per yd. The company intends to hydraulic the upper bench and to dredge the lower ground. Joseph Shebley, manager, with headquarters at Woodville, is constructing a ditch and flume to furnish water for hydraulicking under 200-lb. pressure, and intends to purchase the necessary pipe and apparatus to begin operations within two months. A sawmill is cutting lumber for the flume.

Woodville, September 30.

TEXAS

WEBB COUNTY

(Special Correspondence).—The Border Gas Co., a subsidiary concern of the Texas Producers Oil Co., of Houston, has a large force laying the pipe-line from its wells in the Reiser field to Laredo, a distance of 30 miles. Most of the pipe has been received. This company also plans to extend its line across the Rio Grande to Nuevo Laredo, Mexico. Both of these towns are industrial centres of importance, and are close to some of the largest zinc mines in Mexico, which makes the proposition of establishing a zinc smelter, in which natural gas shall be used for smelting, an attractive one. The situation is being investigated by practical smelter men with this object in view. The Reiser natural-gas discovery was made while boring for oil three years ago. The output of the gas is enormous, and all of the land around Reiser is under lease to oil companies which are exploring the region for oil. The Border Gas Co. will apply to the Mexican government for a concession to lay a pipe-line to Monterey, Mexico, a distance of 160 miles from this place. It also contemplates extending its system to San Antonio, 150 miles north of here. At Monterey there are a number of large manufacturing plants which would use gas for fuel. It is the chief industrial city of Mexico, having two large smelters, a ten-million-dollar steel and iron works, foundries, and various other manufacturing

plants of large size. Many pumping plants are situated along the Rio Grande above and below Laredo where the land is under irrigation. It is planned to furnish these plants also with natural gas for fuel.

Reiser, September 30.

UTAH

SEVIER COUNTY

(Special Correspondence).—The Sevier-Miller Coalition Mines Co., whose mine and mill are situated fifteen miles from Sevier station, and three miles west from the Annie Laurie mine, is mining and milling 40 tons per day of ore that averages $10 per ton. The ore consists of gold and silver-bearing quartz and the metals are extracted by cyanidation. The company contemplates installing a slime plant for cyaniding the slime after separating it from the sand. By such addition it is believed the percentage of extraction can be increased, although the mill work at present is fairly good. The mine is opened by adits driven from the side of the mountain. The ore occurs in veins, having a width of 20 ft. in some places. The mill, air-compressor, and shop machinery are operated by electric power, generated at the company's hydro-electric plant on Clear creek, a tributary of the Sevier river. F. T. Tilden, manager for the company, is a heavy stockholder, as is also B. F. Bauer of the Salt Lake Hardware Company.

Sevier, October 1.

SUMMIT COUNTY

(Special Correspondence).—The Silver King Coalition Co., for which George D. Blood is now general superintendent, has nearly 400 men on the payroll at the mine and mill, the major part of the force being employed on development. On the 1300-ft. level the 12-lb. rails have been supplanted by 20-lb. rails for electric haulage, and provision made for a trolley wire and a large ventilating pipe. An interesting feature of Silver King development consists of the Alliance adit, which starts in Empire canyon, running two miles westerly into what was formerly known as the Kearns-Keith group, but now included in the Silver King area. The laterals driven from this adit aggregate nearly two miles in length, and that part which connects the Alliance adit with the main Silver King workings corresponds to the 500-ft. level of the latter. This adit originally was driven to develop the Sampson ground and to provide drainage for the workings on the Kearns-Keith fissure, and within the last three years the latter have produced a considerable tonnage of profitable ore. An incline raise is being made on this fissure from the level of the Alliance adit to the old Kearns-Keith tunnel, a distance of 1000 ft., making a vertical height of 800 ft. The raise is progressing satisfactorily and thus far it has reached 250 ft. The laterals which go out from this adit serve to develop a number of fissures and beds at a good distance above the Silver King contact, as well as catching surface waters and keeping the Silver King workings dry. The Alliance adit flows 1200 gal. of water per minute, and the pumping plant at the portal, which delivers part of this volume to the concentrating mill, now has a Worthington, 4-stage, centrifugal pump, direct connected to an electric motor, General Electric make, the lift being 450 ft. Additional water for the mill work is conveyed from other parts of the property through surface pipe lines, two miles of which have been laid this year. All ore from the mine, including that taken from the fissures opened by the Alliance adit, is hoisted through the Silver King shaft. The electric haulage being established comprises the trackage on the 500 and 1300-ft. levels, the surface trackage leading to the waste dump, and that leading to the sampler and mill. The shop machinery will also be equipped for using electric power.

Park City, October 3.

WASHINGTON

CHELAN COUNTY

(Special Correspondence).—The Washington Steel & Iron Co., of Spokane, which has a large deposit of magnetic iron ore at Blewitt, is planning to erect a 20-ton smelter near the town of Leavenworth. E. H. Rothert, general manager, says the Rothert process will be installed.

Blewitt, September 23.

FERRY COUNTY

(Special Correspondence).—John Lloyd, general manager of the Knob Hill mine, estimates $5,000,000 worth of ore available on the Lone Pine and Surprise mines in Republic district. The vein has widened to 25 ft. J. W. Twiner, president of the Trade Dollar Mining Co., says that shipments reach 5 cars per day. The value is said to range from $50 to $100 per ton.——Samples of ore from the Swamp King No. 2 Gold Mining Co.'s property at Orient, yielded gold at the rate of $1347 and tellurium at $26 per ton, according to a certificate issued by W. H. Stowell of Spokane. The streak is 18 to 20 in. wide, equalling that of the Swamp King, according to advices received by Charles J. Johnson, the secretary, and was cut at a depth of 25 ft. in a vein that is wider than the shaft. A steam-hoist and compressor may be installed. The company is headed by A. B. Railton of Spokane.

Republic, October 3.

STEVENS COUNTY

(Special Correspondence).—E. C. Regnier, of Boulder, Colorado, of the Blue Grouse Tungsten company at Loon Lake, has gone to the mine to select a site for a sampling plant to cost $10,000. A concentrator and other machinery for the Blue Grouse is also planned. Mr. Regnier announced in Spokane that he will open headquarters here in October and buy all the tungsten ore offered for sale by miners and prospectors in the district. He has already bought more than $1000 worth of ore mined in the Loon Lake region. A discovery of tungsten on the Jupiter claim, a mile east of Blue Grouse mountain, is reported. E. E. Alexander, of Spokane, who made the location, says there is a wide outcrop of granite through quartzite. The Tungsten King company has stored 5 tons of ore. The Blue Grouse company has 102 sacks of ore, running 30% tungsten, ready for shipment.

Spokane, October 1.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The Slocan Star mine is again shipping to the Trail smelter after a prolonged shutdown, during litigation. An amicable arrangement has been reached and an initial shipment of 30 tons of silver-lead ore was sent out.——The Beatrice, one of the most important mines in the Lardeau district, is to be reopened, according to Harry Anderson, of Nelson, one of the stockholders. Over $50,000 has been spent in development and ore reserves have been blocked out. Shipments will be started and work carried on at the 450-ft. level to tap the orebody at that level and a raise driven to the upper level. The Revenue and Spider properties near the Beatrice will begin shipments of ore in a few weeks. The tunnel on the Weiss group is in 150 ft. and should cut one of the smaller veins in a few days. It will take nearly 350 ft. more to reach the main vein. The veins vary from 3 to 28 ft. in thickness and carry 60 to 75% lead and 8% silver, in the pay-streak.——A strong force is at work at the Standard mine, near Silverton. The mine is shipping regularly to the Trail smelter. Recently a 4-ft. deposit of silver-lead ore was opened. The vein on the intermediate level is 10 ft. wide and on the fifth level over 17 ft. in width and carries as high as 73% lead and 80 to 100 oz. silver.——An important strike is reported to have been made on the California group of claims, on Toad mountain. The vein has widened to 3 ft. and an average sample assayed $68.70. The mine has been developed to a depth of 225 ft. J. P. Bell is operating it under lease.——At the Maestro, Ainsworth, the operator, Alexander Grant, has three feet of ore and 14 ft. of lode matter exposed. Shipments will be carried to the smelter as soon as the roads are in proper condition.——The recent forest fires uncovered a new lead on the Society Girl claim, at Moyie, and the company has put 10 men at work developing it. All through the burnt districts prospectors are out over newly cleared ground and some

good finds are reported from Sheep creek and elsewhere. ——Several tons of ore per day from the Aurora mine, at Moyie, are being put through the experimental mill of the Consolidated company for test.——At the Mother Lode mine, Sheep creek, a new tunnel has been started on the second level to cut the vein in the old workings. The property is being developed by John McMartin, of New York, and there being no necessity for shipping ore it is not being done.——A new cross-cut has been started on the Clyde-Belt group, Sheep creek, which is under bond to the Britannia Mining & Smelting Co.——The French Complex-Ore Reduction Co., of Victoria, represented by A. Gordon French, will build an experimental zinc smelter at Nelson. The City of Nelson has leased to the company the old power plant as it will be necessary to generate direct-current for the work. Metallic zinc and zinc white will be produced, and the residue, containing silver and lead, will be sent to Trail for treatment.——Work is to be carried on at the Abestol mine, Poplar Creek district. Asbestos occurs in the seams and slips of the serpentine on this property for a distance of 1200 feet.

Rossland, October 1.

MEXICO

ZACATECAS

(Special Correspondence).—Mining activity in this district is slowly reviving. The Eden Mining Co. is remodeling and enlarging its concentrating plant and introducing Kobbe-Middleton grinding pans for re-crushing the middling and tailing from the Wilfley tables. The finer pulp will then be re-concentrated on Deister and Johnston tables after passing a Richards pulsator classifier. In the earlier stages of concentration Callow screens are to be used for sizing the pulp, prior to passing to different groups of Card and Wilfley tables. J. M. Nicol, of Mexico City, has been consulting engineer for the re-design and equipment of the plant. The custom milling and cyaniding plant which has been operating in the city of Zacatecas for some time past has not been as successful as was anticipated, partly due to the difficulty of successfully treating small lots of varying grades of ore and also to faulty design in the general arrangement of the plant. It is also stated that the San Luis del Oro mines may start work before long; this property is equipped with a 20-stamp mill and a small percolation plant, the latter one of the first to be built in Mexico. The mine has been idle for several years. It is situated to the south of Zacatecas in slate. Another interesting plant, now almost ready, is at the Laguna de Guadalupe, to the east of Zacatecas. The shore of the lagoon has been a catchment basin for several million tons of tailing, which have been washed down from the various old patios and other treatment plants which are scattered up the valley of the Zacatecas. The engineer in charge and who has been largely responsibe for the design of the plant, is Rodolfo Munoz. The plant has been designed to handle the tailing and also the ore from Las Minillas. The tailing will be collected by scrapers at loading stations and transported by tram lines to the plant, which consists of a Blake crusher, two Bryan mills with 40-mesh screen, one Dorr classifier, one Dorr thickener, four 15 by 45-ft. Pachuca tanks, arranged for continuous agitation; one cone receiver and distributer, which sends the leached slime to a Wilfley continuous-action drum-filter and the sand to a Grothe & Carter 75-ft. continuous-action tray filter, with the necessary auxiliaries, air-compressor, centrifugal pumps, and sand pumps. An attempt was made to leach the tailing directly, without re-grinding, but it was found to be too coarse and caused trouble in the Pachuca tanks, and it was found more economical and convenient to slime the whole. The tests on the Grothe & Carter filter showed a capacity, with this class of material, of over 100 tons per 24 hours. Tests have not yet been made on the Wilfley filter and when made, the results will be very interesting, as this is probably the only plant in Mexico in which filters of the drum and tray type are working side by side.

Zacatecas, September 30.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. W. Merrill has gone to London.

Leslie H. Webb is in San Francisco.

Lionel Lindsay has gone to Mexico.

W. C. Bass is at Caliente, California.

George S. Rice was in San Francisco.

F. M. Carlock is now at Mercedes, Texas.

Edward W. Carson is now at Los Angeles.

J. F. Callbreath, Jr., is in San Francisco.

R. W. Brock has gone to British Columbia.

Edgar Rickard and L. A. Greene are at Chicago.

R. R. Belknap has gone to Marysville, California.

C. W. Purington has left East Siberia for London.

J. A. Holmes has gone to Siskiyou county, California.

H. W. Hardinge has returned to New York from London.

Ralph Arnold was at Bakersfield and is in San Francisco this week.

L. A. Sisley, of *The Mining World*, was in San Francisco this week.

Charles Janin has returned from Zacatecas and the City of Mexico.

J. Atkins has moved from Geneva, Colorado, to Glendale, Oregon.

Courtenay Ballagh is now with the El Tigre, at Yzabal, Sonora, Mexico.

L. H. Dyke has left Guayaquil, Ecuador, and is now at Gilroy, California.

Dyke V. Keedy, of Dietz & Keedy, has returned to Boston from Nova Scotia.

O. Ellerman is at Douglas, Arizona, having left Deadwood, South Dakota.

Howard D. Smith has gone to New York. He did not go to London as announced.

Desaix B. Myers will be in Philadelphia till October 15, when he returns to Los Angeles.

M. A. Newman, of the Jesus Maria y Anexas, San José de Gracia, Mexico, is in San Francisco.

L. R. Clapp has gone from New York to Cia. Real del Monte y Pachuca, Pachuca, Hidalgo, Mexico.

P. C. Stoess, who represents Pearse, Kingston & Browne at Seattle, is at Juneau, Alaska, for a short time.

E. R. Buckley visited the Yosemite following the meeting of the American Mining Congress at Los Angeles.

C. B. Kingston has gone to Rhodesia, and Gerald M. Browne will sail from London for South Africa, October 4.

Arthur L. Pearse, of Pearse, Kingston & Browne, New York and London, spent a few days in Salt Lake last week.

J. B. Fleming having completed his work at Goldfield is now designing and constructing a stamp and cyanidation mill for the Nevada Hills M. Co., at Fairview, Nevada.

Members of the Mining and Metallurgical Society of America, under guidance of J. B. Lippincott, inspected the Jawbone, Elizabeth, and Saugus divisions of the Los Angeles aqueduct October 1 and 2. In the party were S. W. Mudd, J. W. Malcolmson, R. W. Brock, H. F. Bain, G. S. Rice, Theo. Comstock, C. D. Clark, S. B. Christy, W. C. Mendenhall, D. T. Day, D. W. Brunton, and J. A. Holmes.

F. L. Ransom, E. W. Parker, S. W. Mudd, J. W. Malcolmson, R. W. Brock, H. F. Bain, J. P. Channing, G. S. Rice, Theo. Comstock, E. R. Buckley, F. J. H. Merrill, C. D. Clark, S. B. Christy, W. C. Mendenhall, E. H. Benjamin, J. N. Nevius, D. W. Brunton, W. F. Staunton, C. C. Jones, T. R. Woodbridge, L. W. Powell, J. A. Holmes, E. A. Montgomery, Sidney Norman, E. W. Bannister, B. L. H. Forbes and E. Higgins attended a dinner of the Mining and Metallurgical Society of America at the Sierra Madre Club, Los Angeles, September 29.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

DECISION OF STATE COURT ON MINING NOT BINDING ON FEDERAL COURTS

The Supreme Court of the United States has recently held that a decision of a State court to the effect that a grantor in a deed conveying coal in place with the right to mine the same cannot maintain an action for damages for the failure of the grantee to properly support the surface of the land, is not binding on the Federal courts.

Kuhn *v.* Fairmont Coal Co., 30 Supreme Court Rep. 140, Jan. '10.

LOCATION OF MINE—RIGHT OF POSSESSION

The posting of a senior location notice on a mining claim which is based on a valid discovery gives the locators the right to such possession during the statutory period as would enable them to complete the location by performing the necessary work, and this right may be protected or enforced by proper action, but the location of a mining claim made upon ground covered at the time by prior valid subsisting location, is void.

Bergquist *v.* W. Virginia-Wyoming Copper Co., (Wyo.) 106 Pac. 673, Feb. '10.

LIEN ON MINE CREATED BY CONTRACT

After persons jointly interested in mining property and for the development of which some of them had made large advances, then entered into a contract giving to the persons having made such advancements the right to manage the property and apply the profits, and in case of a sale the proceeds of the property was to be applied to the repayment of such advances. In an action on the contract involving the rights of the parties, it was held that the contract gave the persons making such advances an equitable lien on the property itself which they could enforce by foreclosure after it was found that the operation of the mine was unprofitable. And it was further determined that threats made by the parties having made such advances that they would make no further advances unless the other party signed such contract, and the mine would consequently be shut down and be rendered worthless, did not constitute such duress as would render the contract invalid.

Connolly *v.* Bouck, 174 Fed. 312.

OPTION TO PURCHASE LEASE—CONSTRUCTION AND EFFECT

A lessee of a mine who had power to assign the lease with the consent of the lessor, gave a third person three different options for the purchase of the lease. At the same time the proposed purchaser delivered a written agreement to the lessee by which he bound himself to accept one of the three propositions, and until such acceptance he agreed to pay the expenses of the operation of the mine by the lessee. Thereupon the lessee accepted the proposition and began working the mine, but on failure of the proposed purchaser to pay the expenses of such operations stopped the work and under the terms of the lease the lessor forfeited the same. In an action by the lessee against the proposed purchaser it was held that the lessee could not recover a monthly rent stipulated in one of the option agreements, as the time not having expired in which to accept the proposition, the proposed purchaser might have accepted another one of the option agreements which did not require the payment of a rental. It was also held that he could not recover the purchase price agreed to be paid for the lease and certain machinery because the lease was forfeited before the expiration of the purchaser's option to accept the proposition, and therefore the lessee had nothing to convey. But it was held that a cause of action existed against such purchaser for the expenses agreed to be paid by him to the lessee for working the mine, as by non-payment the lease was forfeited to the lessees.

Hummer *v.* McGee, (Wis.) 124 Northwest. 302, Jan. '10.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

CONTRACTS AND ENGINEERING. By James Irwin Tucker Pp. 307. Index. $3.50. McGraw-Hill Book Co., 239 W. 39th street, New York.

This work is particularly intended as a guide to contracting engineers in preparing contracts with a view to legal requirements. The preparation of specifications which will stand the test of the courts is an important matter, as many contractors have learned to their sorrow, therefore-properly worded contracts are a necessity.

CHEMISTS POCKET MANUAL. By Richard K. Mead. Second Edition. Pp. 444, pocket size, Ill., flexible back. Chemical Pub. Co., Easton, Pa., 1910. Price $3.

The new edition of this well known and much used handbook, includes a large amount of new and valuable matter. The old text has also been re-written and rearranged. The book is standard and does for chemists and chemical engineers what the manuals of Trautwine, Kent, and Supplee do in other fields.

COMPRESSED AIR, THEORY AND COMPUTATIONS. By Elmo G. Harris. Pp. 123. McGraw-Hill Book Co., New York, 1910. Price. $1.50.

In the preface, the author clearly states the nature of the treatise, and says that no one should be entrusted with the designing of compressed-air plants who is not fully qualified by education and experience to undertake so responsible a task. The work is mathematical and contains much information of value to those employing compressed air or who contemplate installations of that character. It deals with the use of air under varied conditions, as affected by attitude and otherwise, and chapters are devoted to special applications of compressed air; the return-air system, and air-lift pump.

PRINCIPLES OF METALLURGY, being an introduction to the metallurgy of the metals. By Charles Herman Fulton. Pp. 528, index., Ill. McGraw-Hill Book Co., New York, 1910. Price $5.

In this volume the author, the professor of metallurgy at the South Dakota School of Mines, has endeavored to supply a treatise of introductory character, to the study of metallurgy, and he has succeeded admirably. One of the most important chapters in the book is that on slags, which are treated at length; another interesting and important chapter is that on refractory materials for furnaces or furnace linings. The section of the various types of furnaces is also of value, as it is well illustrated with drawings which give dimensions and unusally full details of construction. In short, it is a work which will be equally welcomed by the student and by the experienced metallurgist.

PRACTICAL DATA FOR THE CYANIDE PLANT. By Herbert A. Megraw. Pp. 92, pocket size, Ill., flexible cover. McGraw-Hill Book Co., New York, 1910. Price $2.

This book is, as frankly stated by the author, a compilation designed to give shift-bosses some insight as to the reasons for the various steps involved in cyanidation, and tables needed in daily calculations. Following a brief introduction, are mensuration and conversion tables that in the main are well chosen and likely to be extremely useful. It would have been well to have included such a table as that of W. A. Caldecott by which the slime-pulp capacity of circular vats may be determined directly. Another table that will be missed is one giving pounds or ounces of KCN necessary for any given number of tons of solution of various strengths. It saves calculations and mistakes to have such details figured and checked once for all. However, these and other features will doubtless be added to future editions as demand for them arises. In the meantime, Mr. Megraw has performed a real service in bringing together as much as appears in this book.

SEPTEMBER COPPER REVIEW

By M. E. Appelbaum

During the month of September copper sold as high at 12¾c. delivered 30 days and closed at the low figure of 12½c. delivered 30 days. Transactions were not of a very large nature excepting for steady purchases made by the European buyers where business seems to be exceedingly good. The only feature of interest during the month of September was the publication of the Producers' report on September 8 covering the August output and deliveries resulting in a small decrease in the visible supply. The record production was due to the action of the New York refineries in pushing the production in August, thus making up for the decreased production in July on account of labor troubles and weather interference. The statistics, however, to be published for the month of October, should for the first time show the real curtailment of about 15%, and if Europe and this country continue to consume copper at the present rate, we should, by the end of the year, have a considerable reduction in the visible supply. Several new mines will begin production around the beginning of the year and it will therefore be necessary to continue the curtailment policy in order not to increase the visible supply and furthermore keep the price of metal at a sufficiently low figure so as to permit liberal purchases. Considering, however, that 12½c. copper compared with the present cost of production is equivalent to at least 14c. copper compared with the cost of a few years ago, one cannot help feeling that the metal has given a good account of itself in the face of the exceedingly large surplus, and that with a year or two of real good business the surplus will become normal and higher prices may then be looked forward to.

COMMERCIAL PARAGRAPHS

The name of the firm formerly known as the Standard Engineering Co., of 503 Market street, San Francisco, has been changed so as to incorporate the names of the members, and in the future will be known as Braun, Williams & Russell, Inc. The same line of business will be continued.

The Goldschmidt Thermit Co., of 90 West street, New York, announces that commencing October 1, E. Stutz, vice-president and general manager, retires, William C. Cuntz becoming manager. Mr. Cuntz brings to his position a thorough knowledge of the steel business and a wide acquaintance with the railway and street railway officials of the country, having been connected for eighteen years with the Pennsylvania Steel Company.

The Mine Management Co. has been formed by the association of Henry M. Adkinson, Stuart Croasdale, and R. D. George, to undertake examination and management of mining properties of all sorts. Offices have been opened at 714 Equitable building, Denver, Colorado, and Mr. Adkinson will act as manager. The new company announces that its services are to be strictly professional. It will not be interested in or concerned with the promotion of mines, the sale of shares, or the sale of machinery or supplies.

DIVIDENDS

On Tuesday, October 4, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 157 of $98,100. This makes the amount of dividends paid since January 1, 1910, $843,600 and the total to date $12,129,600.

Spelter is firm at 5.45 in spite of rather indifferent demand, because the signs of a serious curtailment in production owing to gas shortage in a number of Kansas plants are multiplying. A number of plants around Iola which are still running a block or two will have to shut down during the winter, never to be operated again, for the gas on which they depended for fuel has been exhausted or the price has advanced so much, that the use for zinc smelting is impossible. A number of other plants are operating with oil in order to husband their gas supply.

EDITORIAL

THE importation of a large tonnage of pig iron and iron ore from China by the Western Steel Corporation, of Seattle, Washington, is food for thought on the part of those interested in the iron ore deposits of the West.

THUS FAR nothing definite is known of the perpetrators of the dynamite outrages at Los Angeles on October 1, although the police, according to the daily press, is 'hot on the trail' of the criminals. Every right-thinking person sincerely hopes they will be apprehended and punished as their crime deserves.

OUR comment on the Southern Pacific oil lands in last week's issue was founded, as it develops, on a misapprehension as to the exception in these particular patents. This is but the old clause that has been frequently placed in such patents and which has been held by the courts to be void for reasons already suggested.

AS a notable instance of how low mining costs may be reduced when the situation and general conditions are favorable is the fact that the Alaska United Gold Mining Company was enabled to make a handsome profit on its operations for the month ended August 15, on an ore from its Ready Bullion mine yielding but $2.01 per ton. There was crushed 21,140 tons, at an operating expense for mining and milling of but $26,023.83, being $1.23 per ton.

A RECENT decision of the Canadian Railway Commission against the White Pass & Yukon Railway Company in the case of Mr. J. H. Conrad, who claimed the company was guilty of charging extortionate rates for handling ore and mining machinery, is illuminating and should be gratifying to the mining men of the Far North. The railway company had charged Mr. Conrad a rate of $3.75 per ton whereas the Atlas company paid but $2.50 under a secret agreement.

THE GOLD output of the Transvaal continues to increase, as shown by the official figures of the Chamber of Mines for July 1910. Nearly every month for the first half of 1910 shows an increase over the figures for the corresponding period of 1909. The total output from January 1, 1910, to July 31, 1910, was £18,269,244, as compared with £18,084,512 for the first half of 1909. During the period covered by the report, 9806 stamps were dropping and 166 tube-mills were in operation. The amount of ore crushed was 12,576,402 tons, a duty of 6.97 tons per stamp per each 24 hours.

THEORIES as to the distribution of ore near the outcrop of veins occurring near Fairbanks, Alaska, as expressed in a letter from our correspondent at that place, and found elsewhere herein, are of an interesting sort. Whether the facts justify the local conclusions or not we are unable to say at this time. That the frost-line should have any influence on the width of a vein seems strange, and in all probability is merely a coincidence.

AGAIN press despatches bring the news of disastrous forest fires in the middle northern States, and extending into Canada, with the loss of hundreds of lives and the destruction of millions of dollars worth of property. Entire towns have been swept away in northern Wisconsin and the inhabitants either burned or rendered homeless and absolutely destitute. Without doubt this great generous country will not wait for a call for aid from the sufferers but will send food and clothing to the needy.

PRESENT mining activity in Sierra county, California, furnishes an example of the fluctuations of fortune in mining regions. In early days there was no more wide awake and energetic district in the West than existed about Alleghany in Sierra county. The great Sierra Buttes, Young America, and numerous other mines were in operation, and Sierra was prosperous. Then came a long period of quiet, almost idleness, until several rich discoveries were made—and these are what count in stimulating interest—and Sierra county is once more 'in her element' with 'something doing,' every day, and splendid outlook for the future.

CONSTRUCTIVE criticism is always helpful. In this issue we publish a description of a new agitator designed for cyanide work, by Mr. Lee Fraser, in Costa Rica. In out of the way corners of the earth it is not easy for engineers to discuss matters with their fellow workers and in submitting this design Mr. Fraser states frankly that the agitator has not been altogether successful when tested on a working scale. He is hopeful that some other engineer may be able to suggest points that the designer himself has overlooked. Admission of mistakes is not easy to make, and the spirit in which Mr. Fraser has acted will, we are sure, elicit, as it deserves, the helpful criticism of other workers.

CHINA continues to be the centre of interest in the Far East. Beset with difficulties from without and unrest within, the problems of administration have become peculiarly difficult. Between the young men who would make the country over in a day, and the conservatives who dread any change whatever, there is the same struggle as between 'Insurgents' and 'Standpatters' in America. Indeed the analogies to our own country are more intimate than is often recognized. The Viceroys and the Provincial governments are in many things as independent as are our Governors and State governments. The Chinese administration in effect is dual as is our own, and re-establishment of the central authority is a difficult and delicate process. In the meantime, most fortunately, the industrial situation continues to improve, and progress in education is rapid. There can be nothing but good in feeding people well and teaching them to think straight. New railways, new mines, new schools, and visits to foreign countries, are all preparing China for playing a large part in the world's affairs. Americans can well afford to welcome all these evidences of progress though the project, much discussed in the Far East, for an actual alliance between the Empire and the Republic, is too foreign to our policy to meet much favor.

THE reported discovery of large masses of carbonate and silicate of zinc in the mines of Leadville is almost startling. It seems strange that the existence of these minerals had not been observed long since, but such oversights are not without parallel—instance the years from 1860 to 1875 during which lead carbonate was rejected, tons of it, by the placer miners of Oro City (Leadville) when found in their sluice boxes. There seemed some excuse for the failure to recognize the carbonate sand in those days, but it is difficult to find similar excuse for the miners of the present day at Leadville. If statements concerning this discovery are not exaggerated Leadville will become a much more important producer of zinc ore within a short time, than ever before.

The Utility of Conveyors

Conveying machinery is reaching an advanced stage of development, particularly for the purpose of handling minerals. A few years ago about the only automatic conveyors to be seen about mines were in the mills where spiral conveyors were utilized to move ore from the front of the dry-crushing battery to the pit beneath the roasting furnace, from which it was lifted by a bucket conveyor to the hopper above the furnace. Now, conveying machinery is seen in mines, mills, and smelters, in railway yards, and almost everywhere that materials and merchandise are to be moved comparatively short distances. Belt conveyors are used to carry coarse rock from the collar of the mine shaft to the rock-breaker; from the storage bins to bins back of the pulverizing machinery; elevating crushed ore from one level to another; from the stamps or rolls to cyanide vats; and tailing is elevated to the top of high and constantly increasing piles of débris. Everywhere that economy of handling is sought finds conveying machinery at work. Conveyors have greatly simplified the planning of large metallurgical plants. Ordinarily well designed mills are so arranged that the ore, after reaching the top of the mill, passes by gravity through the successive operations of crushing, grinding, and metallurgical treatment, the tailing being discharged at the lowest level of the mill. In very large plants, however, this simple application of gravity is impossible without having a hillside slope 200 to 300 feet in height available, and in such cases the buildings would cover many acres. By the introduction of the various types of conveying machinery the engineer is enabled to plan to handle the ore within relatively limited floor space,

the ore going from one operation to another on belts horizontally or up grades of twenty degrees or more, or vertically by link-belt buckets. The ore is handled dry or wet, hot or cold, coarse or fine. It may be sent in any desired direction and discharged automatically just where it is wanted, and may even be weighed (where this is desirable, and it usually is, though often neglected). In fact, the modern conveyor has been successfully introduced, in one form or another, to meet almost every condition that arises in the handling of ore about metallurgical plants.

Ratio of Value to Depth

The increase, or decrease, of value of ore with greater depth is a subject of practical importance, and one in which every miner, whether working at the face or directing affairs from the office, takes personal interest, and the remarks of Mr. F. Lynwood Garrison in this connection in the department devoted to Discussion will attract the attention of engineers and geologists alike. It has generally been observed that the value of ore decreases with depth in veins, but this depth is relative. A mine may have been profitable—even rich—for the first thousand feet from the surface and then have become gradually, or perhaps suddenly, poorer, thus rendering a paying proposition unprofitable, and the search for better ore at still greater depth has been discontinued and the mine abandoned. It is possible, however, that at greater depth the ore may have been found to become richer. If the exploration is not undertaken it cannot positively be known whether such is the case or not. In the Cripple Creek district of Colorado, for instance, very rich ore is being mined at depths below 1500 feet. Not in as large quantity, perhaps, as was found in higher levels, but of as great value. The Kennedy mine, near Jackson, on the Mother Lode of California, is not only profitable at a vertical depth of 3300 feet, but has produced phenomenally rich ore at 3150 feet vertically beneath the surface, which is equivalent to a depth of over 4000 feet on the vein, and this, after passing through a relatively poorer zone, for several hundred feet above. At the Central Eureka mine, about two miles north of the Kennedy, no payable ore of consequence was found within 1000 feet of the surface, though there were large and profitable orebodies developed below that point. Some of the mines of Grass Valley produce some extremely rich ore nearly 4000 feet below the outcrop, which may be considered as an index of what is possible in that district. Much knowledge of the origin, character, and probabilities of ore deposits has been gained within recent years, particularly since the first appearance of Franz Posepny's monograph on the 'Genesis of Ore Deposits,' and deeper mining stimulated by the occurrence of rich ore at great depth in even a poor mine may result in finding that these occurrences are not isolated and unusual. In the development of the deepest mines of the West it has been observed that there are, in some of them, zones of poorer ore as well as richer, and that the best deposits are not always nearest the surface.

Mining in Western Australia

The mining industry in Western Australia, as indicated by the report of the Department of Mines, for 1909, shows a continued reduction in the output of gold from that of 1908, in which year it was less than in 1907. This, too, notwithstanding that the tonnage of ore treated was greater in 1909 than in 1908. The cause lies in the treatment of ore of somewhat lower grade than in previous years. Concerning the outlook for the gold mining industry, the under secretary of mines says that although practically no outside capital to assist mining operations has been introduced the past few years, yet the outlook is favorable. A number of large orebodies have been recently found and their development proceeds with satisfactory results. The value of the ore is well maintained with increasing depth, and an even more prosperous era than the industry has yet experienced there, is dawning. This is assuredly an optimistic view to take of the situation. One cause of the noticeable lack of energy in new development is attributed to unusual activity in the settlement of new agricultural lands, which has detracted from the ordinary interest in mining. Every effort is made by the government in Australia to foster and encourage the mining industry by loans of equipment and means of transportation, a paternal sort of government procedure to which many object in the United States. There still remains a large field for prospecting in both the old and new districts of Western Australia.

One More Expensive Lesson

Another fatal explosion has occurred in a coal mine in southern Colorado, near Trinidad, in which a large number of men lost their lives on October 9. The cause of the explosion is said to have been due to accumulation of dust in the workings, as it was not generally considered a gassy mine, and safety lamps were not in use, nor was blasting necessary. The usual acts of heroism on the part of those attempting the rescue of imprisoned men, and the scenes of distress at the mouth of the mine were witnessed. After ineffectual attempts to penetrate into the workings an electrically operated fan was placed on a flat-car and advanced into the mine as fast as it was safe to proceed. This is a novel manner of approaching the locality of an explosion in a coal mine, which in this instance occurred several thousand feet from the entrance. Unfortunately the men operating the relief car were unable to proceed far owing to the presence of a large volume of blackdamp which all but suffocated them.

This is but another lesson teaching the necessity of the most rigid investigation of conditions in coal mines, and to bring about which the Bureau of Mines will make strenuous effort. While statistics indicate that the percentage of loss of life annually is fully as large in metal as in coal mines, disaster in the latter usually are accompanied by the loss of life in such numbers as to shock all humanity.

A Geological Journey in Guerrero

By John Wellington Finch

I undertake with some misgiving the following account of a trip of observation in the State of Guerrero, Mexico, because a great amount of territory was covered in a very brief time and a hasty inspection made of some great ore deposits which, if given justice, would have required weeks instead of days. Nevertheless, the Reforma mine, which was in fact the goal of the expedition, possesses features of such interest that I shall attempt a description just as it impressed me, principally because it forms a basis for the theoretical discussion of the genesis of an important and by no means uncommon type of sulphide-ore deposit. I shall be obliged to make free use of data furnished by others, especially by the officers of the Reforma Mining & Milling Co., and by engineers who have made detailed examinations of its orebodies, in order to lend substantiality to conclusions which my own hasty observations suggested. If I fall into error in any particular, I hope even the error may accomplish good by inducing some of the several eminent engineers who have, I know, studied the mine thoroughly, to exercise their altogether too reluctant pens to set the matter straight. Although the Reforma appears to be a really important group of ore deposits commercially, especially in their potentialities for the future, I do not consider myself at liberty to discuss the property from this point of view. This paper will therefore be strictly geological.

Routes of Travel.—From Balsas, the southern terminus of the Cuernavaca branch of the Mexican Central railway, a barge conveyed our party down the Rio Balsas 40 or 50 miles to Pezoapan, the river station of the Reforma company, and situated at the mouth of a tributary canyon, overlooking the head of which, nine miles north, is the village of Campo Morado and the mines. The trip from Pezoapan to the mines was made on horseback over the ridges and mountain crests because of high water in the stream along the canyon trail. The return trip from the mine to the town of Balsas was by saddle across country over the series of high parallel ridges of the mountain range. This journey was continued over two days. The riding time from village to village at good speed was as follows: Campo Morado to Liberaltepec, 3½ hours; thence to Tlanipatlan, 1½ hours; thence to Apaxtla, a miserably filthy Indian village where we unwisely stopped for the night, 2½ hours; then 2½ hours to Tlalsala, 3 hours to Limontitlan, and 2 hours to Balsas.

Location and Topography.—Campo Morado lies, I should estimate, fifty miles in a straight line somewhat north of west of Balsas. Its altitude is about 4200 ft. above the sea, and 3000 ft. above the Balsas river. The deepest level on the principal Reforma vein is 1000 ft. above the main tributary canyon which passes within a mile of the mine. The topographic relief is extreme. If the prevailing rocks were granite, the topography would be rugged, but being comparatively soft shales and shaly limestones, the mountain profiles are smooth and well mantled with vegetation, though steep. Notwithstanding the vegetation, erosion is intense. Trails are difficult to maintain, and reservoirs for power and other purposes silt up rapidly. From June to November rainfall is abundant. In the dry season the surface becomes thoroughly desiccated. The Balsas is a great river, comparable in volume to the Colorado or Snake. It is named from the balsa or barge, which is a strong, heavy, and deep flat-bottomed vessel that has been peculiar to this stream for many generations, and by which the native commerce is floated down, and laboriously pulled up stream by bands of Indians tandem on tow-ropes. The current of the river is swift, and it is eroding its canyon rapidly. The range through which it passes from Balsas to the coast has apparently been recently uplifted several hundred feet. At the time of this visit, though the rainy season had just begun around the sources of the river and there had been only one heavy rain at Campo Morado, yet the water was as thick with silt as pulp in a Pachuca agitator. When running the rapids, pebbles could be heard rapping the bottom of the barge like hailstones on the roof of a house. There is an average of about two rapids to the mile, and they run at the rate of 10 to 15 miles an hour. They appear at curves of the river where it breaks across the tilted shale and limestone strata. The calmer and broader reaches of the river follow along the strike of the softer beds. The river has, therefore, a meandering course.

Geology Between Balsas and Campo Morado.—For the entire 40 or 50 miles the slopes and walls of the Balsas canyon exhibited folded and faulted shales and thin-bedded shaly limestones, both usually dark colored and evidently carbonaceous. They are generally steeply dipping and appear to be recurring strata of the same system. Their prevailing dip to the southwest suggested that these beds were in the western limb of a huge anticline, the eastern segment of which may lie somewhere east of Balsas. No reliable estimate could be formed of the thickness of the beds, but it is certain that we passed at least a mile of strata at one part of the river journey, standing nearly vertical and apparently without repetition of beds. It is a region of extraordinary crustal shortening which must have involved rock readjustment to profound depth. Occasionally an intrusive body was seen, usually as an interealated sheet, or thick sill, coarsely crystalline in texture, and, judging from color and weathering effects, probably belonging to the silicious group. The shattering, faulting, and folding of the intruded bodies, as observed in several cases, proved that a great deal of the structural deformation has been subsequent to their injection through the beds, also the fact that they are usually sills, instead of dikes, suggests that the beds were not greatly fissured before, or at the time of, intrusion. Small areas of effusive porphyry were passed on the return trip.

Near Apaxtla there were evidently several eruptions, judging from the varieties of rock. The porphyry areas are much eroded, but this does not signify great age, because the rate of erosion has been rapid. The porphyries observed appeared on the lower mountain slopes, and in the valley bottoms, but were not seen near the summits of the great ridges which we crossed. It is a reasonable supposition that the topography had become established essentially in its present outlines before these eruptions.

Geologic History of Campo Morado.—In its general features, Campo Morado does not differ materially from the other regions traversed between it and the village of Balsas. There is a closer grouping and greater individual thickness of the intrusive bodies. There are also more notable effects of orogenic disturbance. As I recall the stratigraphic history of this part of Mexico, the sedimentary beds are probably Lower Cretaceous (Comanchean). The large intrusive masses may be named provisionally granodiorite. They seem to be particularly thick at the mines and to thin out each way from it on their strike. This, together with the special exhibition of thermo-metamorphism in the adjacent beds here may indicate that the district is near the source of the magmas. The intrusive bodies strike with the beds about N.60°W., in regular form, but they have great variations of dip, as do the beds. They have been sheared throughout to such an extent that they present a schistose appearance, and they have had much mineral matter added to them and substituted in them. In fact, they seem to have suffered nearly as much metamorphism as the adjacent sediments. I was naturally led to seek a cause of metamorphism later than the bodies themselves.

On the high trail from the river to the mine, a coarse-grained fresh porphyry (possibly monzonite-porphyry) was seen at several points, probably all exposures of the same large dike. At the Naranjo mine of the Reforma group there was some evidence that an unmetamorphosed porphyry overlay the older sill which adjoins the orebody there. The effusive areas east, toward Balsas, are clearly more recent that the granodiorite. Altogether there seemed to be sufficient evidence of two or more volcanic epochs, and that, at some time subsequent to the solidification of the granodiorite, there were instituted the apparently long-continued thermal conditions which accomplished most of the metamorphism, and which were responsible for the extensive sulphide deposits. Although it is entirely speculative, it is reasonable to assume that the dynamo-metamorphism of the grano-diorites was accomplished in the mountain-building period of Tertiary uplift, and that the more recent dikes and ejectamenta of the region are late Tertiary.

Reforma Mine, Campo Morado, Mexico.

The Orebodies.—The sulphide ore consists of practically solid masses of pyrite with small amounts of chalcopyrite, sphalerite, and galena filling fissures and replacing the beds, usually along contacts with the bodies of granodiorite. They resemble the Rio Tinto deposits in form and relations to contacts, but the ore in composition is more like the Mt. Lyell pyrite bodies, of Tasmania. The Reforma body has an average width, in six levels, of about 100 ft. and has been shown to be continuous through the mountain. The sixth level develops the pyrite about 2000 ft. on the strike between the oxidized zones at each end of the level. The Naranjo body lies south of the Reforma and approximately parallel. This body seems to be an almost total replacement of a large elongated body of slate surrounded by intrusive rocks. The slate structure is preserved in the pyrite in places and approximately in the middle of the body a small remnant of slate remains unreplaced.

The Mamey body, recently opened, is developed chiefly in the oxidized zone. It lies north of the Reforma. It was not apparent, from the attention which I gave it, whether it had any relation to a dike contact. It was my impression that it was an isolated replacement deposit formed through a fissure in the slates. All the orebodies dip toward the southwest. Other similar parallel bodies are said to be in process of development at a number of points near Campo Morado to the southwest on other properties which were not visited. The following discussion, though it applies in most particulars to the other lodes at Campo Morado, will refer especially to the more completely developed Reforma body.

Theory of Genesis of the Pyrite.—During the uplift period the Reforma sill of granodiorite was tilted and folded with the beds. Incident to this was the development of fissuring and fracturing along its contacts in the less resistent sediments. In the subsequent period of thermal activity the sediments, being highly carbonaceous were ideal precipitants and, being crushed and shattered, their lime, silica, and alumina were prepared for rapid solution and sulphide substitution. The extent of the fissuring must be largely inferred. Evidences of it do not show clearly in the foot-wall beds. The fractured material has been thoroughly healed by metallic deposits. The walls of the ore, though curving locally, are yet quite regular and the vein has such uniformity of width as to suggest a replaced, broad, fissured zone, and not an irregular extension by replacement into the slates from a narrow fissure; such, for instance, as in the Coeur d'Alene lead deposits. The unreplaced diorite in the hanging wall shows best evidences of the extent of fissuring. Adjoining the ore there is a broad zone of brecciation in the diorite cemented by silica and other nonmetallic minerals. The great duration of the period of stress is suggested by the sheared or schistose condition of the granodiorite. Granodiorite of this texture is brecciated adjoining the lode, showing that the state of stress which culminated in fissuring occurred long subsequent to the intrusion of this body. Before metallization began, the fissure was probably a broad fracture zone not less than 150 ft. wide, 100 ft. of this being largely fault clay and fragments of slate, which was later replaced by ore, and 50 ft. of less shattered granodiorite, which was not so susceptible to replacement and was merely cemented. The granodiorite did not supply the thermal conditions which created the metallic deposits, but merely transformed the shales into slates for a certain distance from contacts. Without going into greater detail, there is reason to believe that the main metallization was effected during modern volcanic epochs, and that the older granodiorite bodies merely served as hard layers along which strain might become concentrated, forming fissures of great length and probably to profound depth. The sheared and shistose diorite contains a notable amount of disseminated sulphides. Megascopically no evidence was seen that any of these disseminated minerals were primary constituents of the rock, but a good part of them were clearly subsequent filling of fractures or lines of shearing. The longitudinal-section sketch illustrates in a general way, as now developed, the relations of the deposit to the topography, and the division into oxidized and sulphide ores. The sulphide ore is dense and fine grained, and in many places the grayish-white pyrite groundmass shows little or no visible crystallization, the other sulphides standing out like phenocrysts in porphyry. To the eye the pyrite mass shows almost no variation from point to point on strike or dip. On the deepest level it has a uniform mineralogical appearance from the oxidized ore on one side of the mountain to that on the other side. Assays, however, indicate a grouping of certain of the metals. The best copper, gold, and silver value lies along the foot-wall, where there is a comparatively regular band averaging at least 20 ft. in width. This band is clearly defined on assay plans and contains an average assay in gold, silver, and copper from two to three times that in the middle of the vein. On the hanging wall side, the assays are a little higher in many places, but there is not a continuous band or shoot. At the west end of the sixth level, the higher grade ore extends across the entire width of the lode, about 125 ft. The following table shows the variations of the metals, each assay representing the entire width of the vein. The gold seems to vary somewhat with the zinc and the silver with the lead. The figures do not represent values, but only numerical variations.

Cu.	Zn.	Au.	Pb.	Ag.
23	51	14	29	89
14	37	5	15	23
17	48	11	21	85
6	13	6	3	25
7	33	10	20	60
13	41	12	17	94
7	18	3	4	13
13	20	5	12	28
7	23	6	12	34
6	16	4	3	21
5	21	26	35	98
7	38	4	17	25

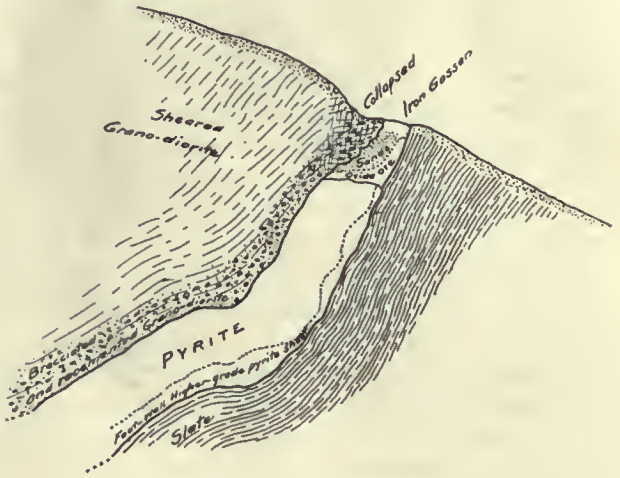
There is some quartz gangue in the ore, as shown by analysis, but it is usually difficult to distinguish underground. In the upper part of the zone, this shows as a fine residual sand, and in places at the bottom of the oxides just above the pyrite, where the lode has not collapsed as it has near the surface, specimens of quartz can be found which at first seem to be massive gangue matter, but which when removed and examined are found to be as light as a dry sponge. It is a filmy coherent skeleton from which the pyrite has been leached. The pyrite and all the other sulphides, as well as the pervading silica gangue, have distinctly the appearance of having been deposited contemporaneously. The ore contains less than 0.005 CaO usually, but it is seldom absent in the scores of analyses which have been made. Arsenic occurs in about the same amount, possibly as an impurity in the pyrite. The iron averages about 36%, the sulphur from 38 to 40, the excess over that required by the pyrite being combined with copper, zinc, and lead. The prevailing copper mineral is chalcopyrite. The gold, silver, and copper at present market prices divide the assay value of the ore almost equally between them.

Lode Structure.—The only structural feature apparently inherent in the pyrite mass is an imperfectly developed system of transverse joints standing at right angles with the walls, probably developed by decrease of temperature and a slight shrinking of the sulphide. These are not sufficiently continuous nor so connected as to form continuous water channels. There are several cross breaks and fractures through the lode, two of which are of some magnitude and have faulted the lode. There has also been a certain amount of post-mineral movement along the foot-wall, possibly induced by the cross-faulting. All of these fractures are extremely recent, as there is little visible oxidation or other alteration along them. The walls of the pyrite are sharply defined. They curve sharply, but I did not observe anywhere a rough or jagged outline of penetration of the wall rock by ore.

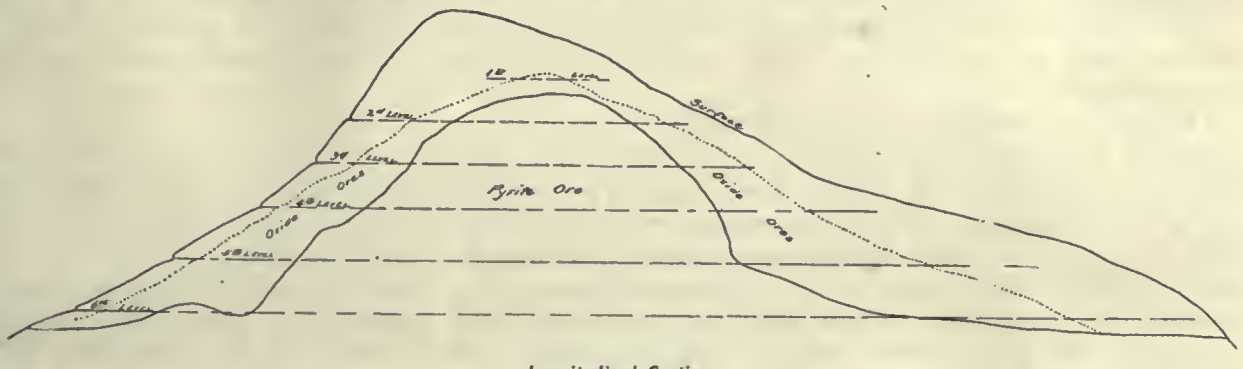
Oxidized Zone.—The top of the oxidized zone is a capping of the usual iron gossan. Below this is a mass of loose quartz sand on the hanging wall side. On the foot-wall side is a body of lead carbonate and oxides of iron, extending upward nearly to the surface and widening downward to the pyrite, at the top of which it extends across the whole width of the lode. The analysis of this ore is 25 to 30% FeO, 25 to 30 SiO_2, 8 to 12 Pb, 1 to 2 As_2O_3, and considerable gold and silver. All the materials of the oxidized zone are residual in origin. The cross-section sketch illustrates a typical occurrence.

Water Level.—In the foot-wall slate, the water level, before the adits drained the ground, was at about the fourth level. The pyrite mass, however, probably always remained saturated to its top throughout the year. The pyrite is not, of course, impervious, but the water which it contained may have stood in it for an age after thermal activity ceased, being held there in sub-capillary spaces, resisting ingress of the annual rains and itself not free to escape. Surface waters enter the slate wall rocks and the recent fractures quite freely, but I believe they have not flowed downward into the massive ore to a notable extent.

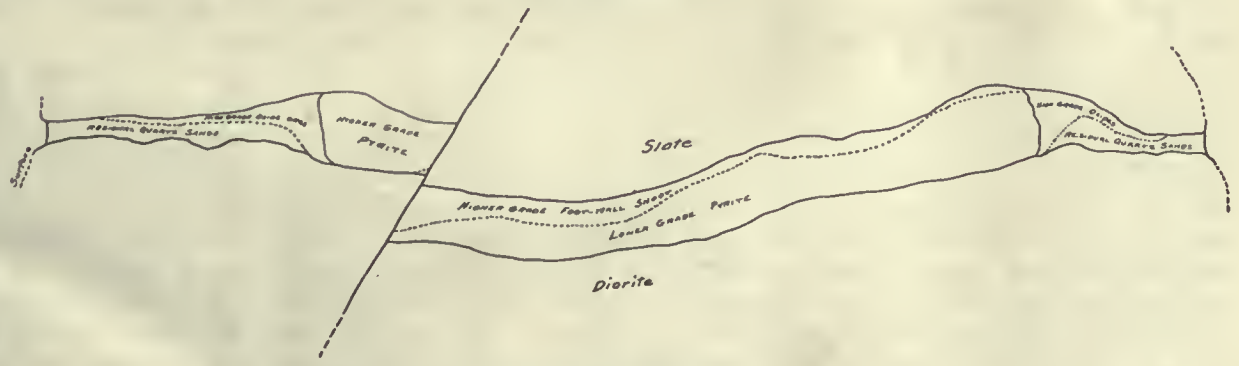
Oxidizing Processes.—There has been very little concentration of copper minerals in the oxidized zone. The copper in solution has drained laterally along the gossan to the surface or through the foot-wall slates. The lead and silver have formed insoluble mineral compounds and are preserved in the oxide ores as shown in the sketches. There is also some enrichment by concentration of gold in the oxide ores. The zone of attack of oxidizing agents in the sulphides appears to have been measurable vertically in inches along practically all the profile of the pyrite.



Ideal Cross-Section Looking West.



Longitudinal Section.



Generalized Plan Diagram.

Descending Sulphide Enrichment.—A little covellite has been found at the top of the pyrite in the Naranjo workings. The superintendent, who is an

engineer and a particularly good mineralogist, states that none has been found in the Reforma. My inquiry as to chalcocite brought the response that it had not been recognized in the pyrite. I saw none.

The higher grade pyrite in the shoots along the walls revealed nothing to the eye which would indicate any sulphide enrichment from above. It is believed that the ores of such shoots were formed by metasomatic replacement from ascending thermal ferruginous solutions which were richer in copper, lead, gold, and silver in the latter part of the long period occupied in replacing the great mass of fissured slate, or, what is equivalent in effect, that the iron in solution became somewhat depleted, thereby increasing the proportionate amounts of the other metals. The line of demarcation between the oxidized ores and the sulphide ores is nearly as sharp as the contact between two rock formations. In profile it is regular and conforms to that of the hill, as would be expected because of the great homogeneity of the mass. In cross-section the top of the pyrite is a flat surface across the vein at the base of the zone of oxides. There is no irregular penetration by the latter. Oxidation is complete as deep as it extends. Along the recent breaks no oxidation or addition of materials not found in the adjacent massive ore was observed, except stalactites and crusts of iron and copper sulphates which have been formed rapidly by water percolating through the fractures, since the adits were driven and ground-water became lowered to an artificial level.

In the planes of crushing along the foot-wall much driving has been done and a theory has arisen that such crushed and soft pyrite is richer than the massive pyrite. Assay maps, however, support the probability that this was richer before it was crushed than the middle of the vein, but it is not shown to be richer in average value than the adjoining massive pyrite of the higher grade foot-wall shoot. If the low-grade mass at the east end of the sixth and fifth levels, where the foot-wall shoot is thin, be averaged in with the other parts of the lode on each of these levels separately, it will give the appearance of a gradual diminution of copper, gold, and silver from the fourth level down. If, however, the lode be divided into shoots, as the assays define them, the results show striking uniformity in both the higher grade and the lower grade bodies. The assays, if so employed, afford no argument for secondary downward sulphide deposition. The lowest grade pyrite, at the east end of the sixth level, is immediately adjacent to the oxidized zone and lies under large bodies of rich lead ores. On the other hand the highest grade pyrite, along the foot-wall, has been developed recently on the sixth level at the place most remote from the oxidized zone.

Acknowledgments.—I wish to express my indebtedness for access to the workings and for many useful and interesting data to the owners and operators of the mines, Don José Maria Ortiz, Don Vicente Ortiz, and to Enrique Ortiz, the superintendent, and to the several other engineers who have at different times been in residence at the mines, whose maps and sketches I was privileged to inspect.

The Black Hills of South Dakota—IV

By William H. Storms

Of the early days in the Black Hills many interesting incidents of the mines might be related—some of them too good never to be placed on record in some manner. Among these is the story of an inexperienced young fellow who was, nevertheless, wide awake, and who not only embraced an opportunity, when it presented itself, but who was prompt to recognize an opportunity at sight. One day he was making a casual call on a friend in Deadwood, who, being a draughtsman, was engaged at the time in making a claim map of the mines in the vicinity of the Father DeSmet mine. Like all claim maps of districts in the Western States, it indicated numerous rectangular blocks lying at many varying angles, frequently overlapping and encroaching upon each other in the utmost confusion. Almost equally were the triangular-shaped blocks, polygons, and other angular forms of unnamable design, and of many sizes. The visitor remarked on this fact, and inquired who owned these odds and ends, and was informed that some were fractional locations, while others still belonged to the public domain and were the subjects for location by anyone disposed to possess himself of them, by merely setting up a 'discovery' stake at some convenient point on the vacant ground.

For some time the young fellow silently studied the map, which was nearing completion, asking questions occasionally about different mines and about certain odd blocks situated in various parts of the map. After a time he announced that he 'must be going,' and accordingly took his departure. He went at once to a stable, hired a horse, and rode up the gulch to Golden Gate and upon the hill above the DeSmet mine, where he spent some time in the investigation of the numerous claim stakes and monuments, being eventually able to identify those he sought. He thereupon located a vacant piece of ground, which in shape resembled a coffin, and was about 400 feet long and 80 feet wide at its widest place. It joined the Father DeSmet, and was directly over the very heart of a large and valuable orebody. He set up his discovery stake, as he had been told, locating the fractional claim. Strange to say he was unobserved all this time, probably because it was no uncommon thing to see men rambling over the hills. He hired a couple of men and set them at work. This was observed quickly enough, and efforts were made by threat and intimidation to dispossess him, but he happened to be one of the kind not easily intimidated, and continued the work of sinking his shaft under an armed guard, maintaining possession until he sold the claim a short time after for, it was said, $60,000.

The owners of one of the claims now constituting the Homestake group were much in need of financial aid and sought it in Deadwood, where they were fortunate enough to enlist the interest of a merchant

who gave the prospectors $100 worth of provisions for a one-tenth interest in their mine. Later the merchant, H. B. Young, became so well pleased with the prospect that he had a drift run in on the ore-body at his own expense, without acquiring any additional interest in the property. Still later, when an offer of a good large sum was made for the mine, and which was entirely satisfactory to the miners, Mr. Young objected, asking a higher price for his interest and insisting as a condition to the transfer, that he be permitted to remove all the ore he had caused to be taken out from the adit and in addition to that, as much more as he could take out in the succeeding 20 days. This was finally agreed to, but the document was loosely drawn and no stipulation was made confining Mr. Young's activities to the advancement of the face of the adit he had run. The following morning he had a crew of men at work, breaking down the ground over the adit, and this opening soon grew to very respectable dimensions as an open-cut, in which he increased the number of men as fast as he could find room for them. Every available custom mill in Lead and Poorman was engaged to crush ore from Young's open-cut, and teams were kept busy, night and day, hauling the rock away as fast as it was broken down, throughout the 20 days of the agreement. On this little operation Mr. Young was said to have netted $8000, which in addition to the $10,000 he received for his one-tenth interest, made a total of $18,000—a most satisfactory return for a $100 grubstake. This incident gives some idea of the value of the ore in some of the veins at and near the surface in the Homestake group in those early days—it was not all low grade.

Another incident of the transfer of a mining claim, in a manner out of the ordinary, was that in which a man named O'Leary, who was one of several partners, refused to sell out at a price which was satisfactory to all concerned excepting himself. O'Leary remained in his cabin on the claim and refused to go down to the town, or to allow anyone to come on the claim to discuss the matter, so suspicious was he of dishonesty in connection with the business. He said: "$10,000 in cash—no checks—spot cash," to him in hand paid at his cabin, and he stood ready to enforce his position, for he refused to give up possession until the cash had been paid over. Finally, the money was sent up under a flag of truce, for it was feared he might attempt to shoot anyone approaching the cabin on the hillside, if it were not made clearly evident that he was in no danger. Immediately upon receiving the money, he put it in a valise, and leaving everything else in the cabin, he watched from the door, and when he saw a hack coming down the road on the way to Deadwood, he walked hastily down the hill, got into the hack and went to Deadwood, leaving the country the following day, taking his money with him. Miners are often suspicious, but seldom do they show such entire lack of faith in their fellow men, or in their ability to take care of themselves, as O'Leary did in this instance.

There are men today, and probably always will be, who seem to think that a dollar made by dishonest means is worth several dollars made legitimately. A saloon keeper in Deadwood owned a mining claim in Sheeptail gulch, near Central City. He had had an adit run in 50 or 60 ft. on the vein and some gold had been found, but not enough to satisfy the owner. Being of an ingenious turn of mind he concluded to undertake the task of improving on the work of the Almighty. He bought a lot of tools suited to his purpose, and with them drilled small holes in the soft seams of the rock. In these holes he placed a mixture of sand, clay, and fine gold, filling and tamping each hole carefully and obliterating as far as possible all traces of his clever work. During six months he put in many a day at this self-imposed task of salting his worthless mining claim, preparing it for the coming of some one, at some future time, on whom he might unload at a good snug profit. One day toward the end of the six months, he went up to his hole and got very warm in climbing the hill. He sat down in the adit and cooled off, and at the same time caught a severe cold which rapidly developed into pneumonia, and in 48 hours he was a dead man. His adit was visited, and the curious set of drills and other instruments he had employed in his work were discovered. Their unusual character led to an investigation, and then was discovered the use to which they had been put. Poor fellow. He might have done far better with his time, talent, and patience.

Never, perhaps, was the value of a knowledge of mineralogy better demonstrated than in the following well authenticated instance: Among the early mines to be opened on the Cambrian conglomerate at Lead, was the Durango. This claim was situated on the hillside west of the Homestake, and in appearance resembled those on the east side of the gold belt, which had paid well, but the cemented gravel of the Durango contained too little gold to make it profitable. This the miner could not understand, but to the geologist the reason was plain. The conglomerate was formed of the detritus of the crystalline schists of the Algonkian, as it was eroded by action of the elements. The region was slowly sinking, and as it sunk the waves continued to encroach upon the land. The angular fragments of rock were tossed and rolled by the waves and soon lost their sharp edges, in time becoming smooth and polished as they were washed to and fro in the surf. The softer portions of the rocks were reduced to sand and silt, and mingled with the pebbles and cobbles, forming gravel. As the sea slowly advanced, the conglomerate covered the schists, in time reaching the great gold-bearing outcrops of the gold belt. For some time the gold derived from the degradation of these outcrops had been washed down and mingled with the gravel of the shore deposit. After a very long time the gold-bearing zone itself was completely covered and then, although the conglomerate continued to be deposited as before, it was no longer gold-bearing, or at least only slightly so, and it was here that the Durango mine was located, where the source of the gold in the conglomerate was buried beneath the bed previously formed. It is well to note, at this point, that the conglomerate contains

no fragments or pebbles of any of the eruptive rocks now so abundant about the Homestake region. The conglomerate was formed at the base of the Cambrian in the Black Hills (equivalent to the middle Cambrian of the Rocky Mountains), while the igneous rocks of the region referred to were erupted after the close of the Cretaceous. This fact, in itself, proves that the Algonkian schists were gold-bearing before the introduction of the eruptive rocks of the district.

Overlying the conglomerate of the Durango mine was a bed of dense quartzite, which at that point was heavily impregnated with a black iron ore. Thousands of men, most of them miners, had seen this ore from the time it first was uncovered by the prospect work on the Durango mine in 1776, up to 1899, but none of those who saw the ore considered the mineral of any particular value, believing it to be some kind of iron ore. In January 1899, a professor in the public school at Lead City, was taking a stroll about the hills and chanced to pass along an old ditch that had been run across the Durango claim years before. When he came to the Durango dump he stopped to examine the ore lying about so abundantly, and picked up a piece of the iron ore. Its unusual weight at once attracted his attention, and he correctly suspected it of being a tungsten ore, which a test at the laboratory quickly confirmed. Ore to the value of $25,000 was shipped from this deposit as the direct result of this knowledge, in which the discoverer participated.

As a sequel to this discovery, Otto Grantz, an owner of numerous locations, began prospecting operations on one of his claims known as the Hidden Fortune. He sought wolframite, but found little of the mineral; he did find, however, gold in considerable quantity, taking out over $70,000 in two months.

As has been stated in a former chapter, water in the vicinity of the great mines of the Homestake Belt, that was readily available, by gravity, was scarce in the early days—that is, water for milling purposes on a large scale. In 1878 the Father DeSmet company expended about $400,000 in the construction of a ditch and flume line which was intended to bring a large quantity of water to Central City from the main Spearfish canyon, for use in the 100-stamp mill and for such other purposes as might require it. Hundreds of men were employed; sawmills were built out in the mountains miles from any settlement, but near the line of the canal survey. Millions of feet of lumber were cut and miles of flume built, besides miles of ditch completed. Six miles northwest of Central, in a direct line, and near the site of the town now known as Carbonate, which was afterward built, two tunnels were driven through hard rock, one of which was 1500 feet in length, and the other nearly as long. These were on the canal line and were designed as part of the system. The plans also contemplated several large and expensive 'inverted siphons,' the pipe for which was brought and delivered, but the big job was never completed—for the reason, as was stated by some, that water could not be made to run up hill, from which it may be inferred there had been an engineering blunder.

In those early days any proposition which promised a permanent water supply was valuable. No one then in the country realized better than Samuel McMasters, the first superintendent of the Homestake, the scarcity, and consequent value of a permanent water supply, and he was ever alert to learn of new sources of water that might be developed, if necessary, and brought to the mines. Some prospectors had located a claim in Nevada gulch, about five miles from Lead. They drove an adit on the vein and had an encouraging prospect of gold, but the vein was small and they were much troubled by an unusual amount of water, which flowed out of the adit like a small river. One day McMasters rode up that way, on one of his frequent trips of observation. He did not fail to promptly notice the fine stream of water issuing from the adit of the prospectors, and dismounting, engaged the miners in conversation regarding their mine. After a brief examination he agreed with them that they had a fine prospect, but, as yet, a long way from being a mine, besides which, he assured them that they would find the water a very expensive proposition to handle when they commenced to sink, which was the thing next to be done if they hoped to develop a permanent mine. After considerable talk he inquired what they would take for the prospect. They promptly asked $10,000, evidently having made up their minds to this previously, with no idea that the great Homestake company would ever so much as look at their little prospect. After considerable haggling on both sides McMasters is said to have offered $6000 cash, which the prospectors accepted. The transfer was made the following day, but when the men returned to their cabin a day or two later, they were much surprised to see several men industriously digging a ditch in which a wooden box-flume was being laid as fast as the ditch was completed, and then covered with earth. They found a substantial bulkhead in the adit and the ditch headed for the Homestake mine. They looked at each other for a moment, in silence, and then one of them said, "It was the water." "Yes," replied the other, "I thought it was damned funny that McMasters would buy this little prospect—it was the water. We sold out too cheap."

Over in the Nigger Hill district, the men who went into that region in the latter part of 1875, and early in 1876, 'struck it rich.' The placers of Bear gulch, Sand creek, Potato gulch, and other smaller streams heading in the high ridge known as Nigger Hill, were rich in coarse gold. Not only were the stream beds rich, but the dry gulches and draws at the very heads of the streams of the district, and in some instances the flat tops of the hills also were rich—some of the dry diggings paid better than any other place. In some respects the dry placers of the Central Hills resemble those of Nigger hill, of which, more later.

The negroes who discovered this district were mostly from Montana, where they had worked in the placers in that State, so were not unfamiliar with the work. The district is isolated from the other mining districts of the Hills, constituting a separate domal uplift exactly typical of the main Black Hills uplift. Here also the Algonkian schists and intru-

sive granite are exposed at the surface by the erosion of the sedimentary beds, the exposed edges of which encircle the area in a series of wall-like scarps. The early adventurers found pay gravel the first day spent in the district, but the best was found later, where they least expected to find it, in the flats and shallow draws on the summit of Nigger hill. A number of small gulches ran down the slopes of the ridge, among them, Potato, Mallory, and Shirt Tail. These were all rich in coarse gold and were worked out in the course of a few months. In one instance, a miner worked industriously on his claim situated on Mallory gulch, up near its head. By working early and late, packing the dirt several rods to a water hole and washing it in a rocker, he was able to make from $3 to $4 a day, but this was no wages for those times, and on learning that men were making $10 a day and over, on Whitewood, near Crook City, he quit his dry diggings on Mallory gulch and made haste to Whitewood. A negro, well known to everybody in those days as 'Nigger Miller,' appropriated the claim and went to work. He found the gold coarse, but not as abundant as he wished, so he concluded to strip a little piece of ground and work only the dirt taken a few inches above bedrock, thus taking the cream of the deposit. He was much disappointed to find, when he came to wash the dirt, that he had nothing. He thought this strange, and concluded to try again, taking the earth in horizontal sections, about six inches deep, at a trial. He found little or no gold the first 30 inches below the surface, but at that depth he found the pay-streak and held it by careful prospecting. He worked the claim out and told me that he made on an average over $30 a day. This man Miller was the enterprising fellow who took his placer outfit to the Centennial exposition, at Philadelphia, in the summer of 1876, after his clean-up on top of Nigger hill, and there washed gravel for the edification of the thousands who passed.

The miners of this district were troubled from the first with a heavy, dark-colored sand which accumulated in their sluices, concentrating with almost the facility of the gold, as it seemed. It was the bane of the clean-up, and were it not for the fact that the gold was coarse and heavy, the loss in gold must have been considerable. This material they thought to be iron ore of some sort and of no value whatever, so it was thrown out wherever found, and it was not until 1883 that they learned that their 'black sand' was mostly cassiterite. Just prior to this discovery tin-stone was found at the Etta mica mine, in Pennington county, near the old village of Harney.

The Etta mine had been worked for mica, but with small success. When it was learned that the mine contained tinstone its development was vigorously continued, and in 1885 a concentrating mill was built near the mine to treat the rock from the Etta and other mines owned by the company in the district. The mill was an elaborate affair, and designed for large capacity, but the development of the mine proved disappointing, for there was not enough tin-bearing rock to keep it in operation.

THE KOSAKA COPPER MINE OF JAPAN

The Fujitagumi is one of the largest commercial enterprises of Japan, according to the report of K. Tsujimoto. Its principal business is mining, and its chief mining operation is the Kosaka copper mine, situated in the province of Rikuchu, near the northern end of Hondo, the largest island of Japan. The mine was discovered in 1861 and was first worked for silver. It continued to be worked as a silver mine until 1897. Up to that time operations had been confined largely to the oxidized zone, but the sulphides becoming more abundant with depth, preparations were made to treat the ores, which are complex sulphides (black ore), for the copper contained, the silver and gold becoming by-products of the operation. The ores contain considerable zinc, but the copper predominating, the zinc has received little attention thus far, though experiments are being made on the copper slags with a view to recovering the zinc from them.

The ores occur as impregnations in sandstone at and near the contact of a dike said to be liparite (a felsitic purplish rhyolite). The block of ground thus far explored it 2200 ft. long, 800 ft. wide, and 500 ft. deep. The minerals are chiefly pyrite, chalcopyrite, blende, galena, and barite. Silica is abundant in some parts of the deposit. Ore mixtures are thus possible which fuse readily in the furnace. Mining was formerly carried on by underground stoping but this method has been abandoned for the open-cut bench, in general after the system in vogue at Mount Lyell, Tasmania. There is a vast amount of overburden to be removed, estimated at 8,000,000 tons. The glory-hole is now 2200 ft. long by 1000 wide at the top and the sides of the pit are as steep as it is considered safe to make them. From 2000 to 3500 tons of overburden, and 1000 tons of ore are removed daily. The ore is taken to the smelters 6000 ft. distant from the mine, by electric railway. Pyrite smelting with a 10-oz. cold blast is the practice. The Japanese metallurgists have succeeded in making a success of introducing 3% of carbonaceous fuel (coal) into the zone of fusion through the tuyeres. The matte runs 30% copper. This is re-smelted to 50% matte which after crushing, is calcined in a Herreshoff furnace, and later reduced to blister copper in a reverberatory. Two stands of converters are being installed to replace the present method of desulphurizing the matte to 'blister.' Electrically operated cranes, tamping machines for lining converters, and other accessories of a modern smelting plant are being added. There are seven smelting furnaces, of which the newest is the largest, being 60 ft. long by 3 ft. 6 in. wide at the tuyeres. There are 116 tuyeres of 6-in. diameter. The slag from the second matte contains a quantity of lead and copper. This is re-smelted and the lead extracted as 'bottom,' which is squeezed in a liquation hearth, and the lead is desilverized in a Parkes pot. The zinc scum, which contains gold and silver, is distilled and the bullion sent to the mint. The output annually is about 11,000 oz. gold, 1,125,000 oz. silver, 15,000,000 lb. copper, and 278 tons lead.

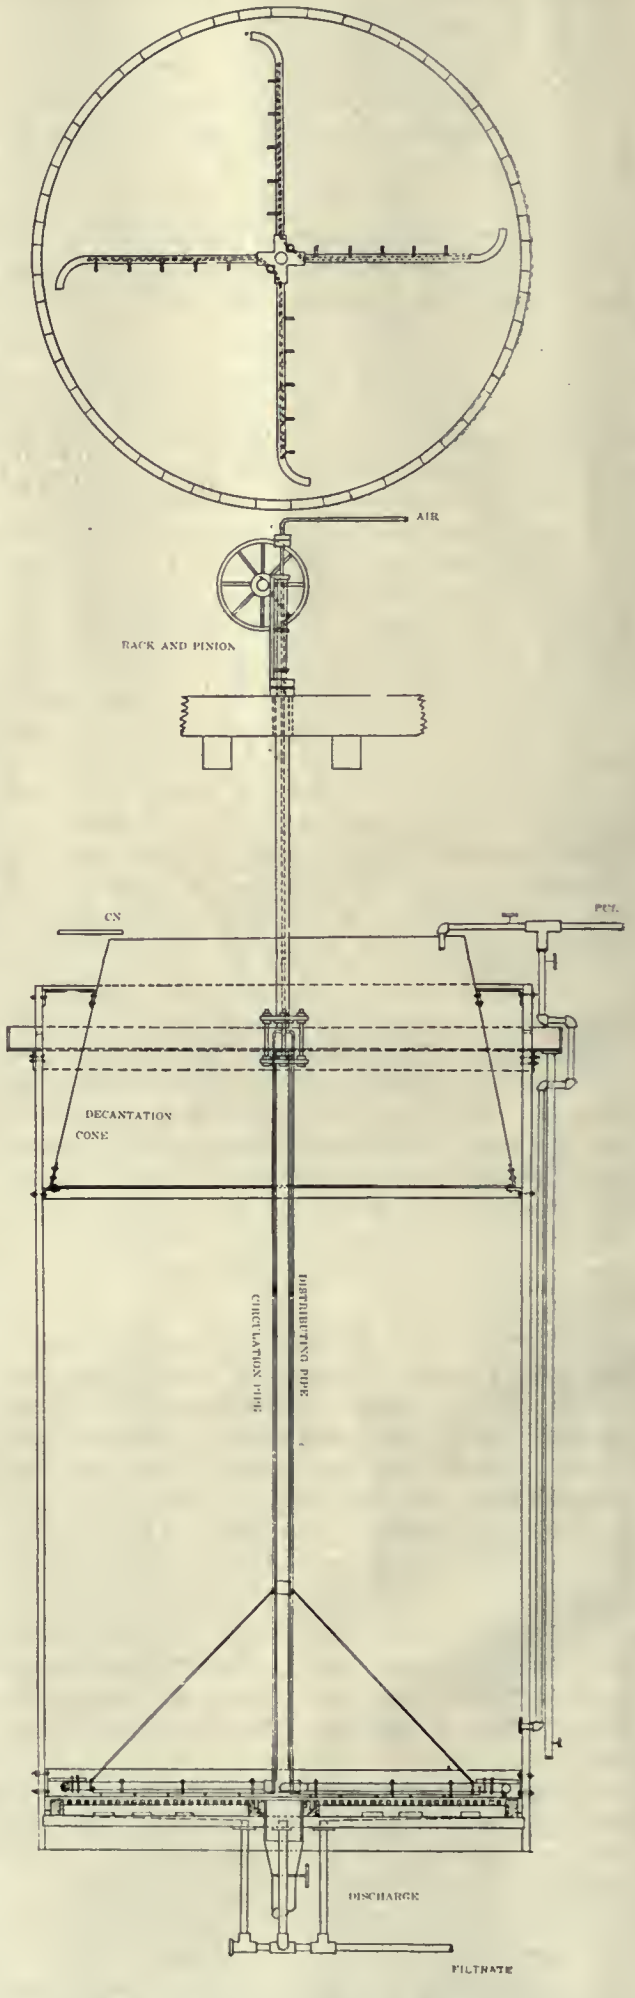
New Cyanide Device

By Lee Fraser

The rate and extent of the dissolution of gold and silver in cyanide solutions depends almost wholly upon certain variable conditions, the most important of which are: temperature, cyanicides, concentration of solution of cyanide, relative proportion of volume of solution and mass of substance, physical condition of solution and substance while undergoing treatment, oxygen, area of metal exposed to solvent, and physical condition of metal to be attacked by solvent. Various machines have, from time to time, been contrived, designed to take an especial advantage of one, or a combination of several of the above conditions, to effect a complete dissolution of the precious metals contained in the substance under treatment. To this number, already extensive, I propose here, to add another. The function of the agitator in slime treatment is to create and to maintain a physical condition of the solution and substance, most advantageous for the progress of the chemical reactions in dissolving the gold and silver. The variable conditions whose regulation, to give maximum rate and extent of dissolution of the gold and silver, lies within the scope of the agitator, will generally comprise: temperature, physical condition of solution and substance undergoing treatment, oxygen, and cyanicides. With but one notable exception, the numerous types of agitators have confined themselves to the regulation of the three latter conditions, neglecting the first.

As in any machine, further considerations of efficiency, first cost, and cost of operation, are of vital importance, so that even though a certain machine may make possible a decidedly increased extraction over another, its operation may be prohibited, on account of its failure to compare favorably with other machines, in one or all of these conditions. In the agitator, shown in the accompanying sketches, it has been aimed to regulate only the last three of the first mentioned conditions, and to provide an efficient, economical, and inexpensive machine. It has been designed to also perform the offices of pulp thickener and collecting tank, in which capacities it greatly simplifies any installation of equipment for the treatment of slimes.

It is contemplated that a cycle of operations will consist in the following: The pulp from the classifier is charged into the tank, preferably through the lower outlet, simultaneously with the admission of air into the distributing pipes. The tank is allowed to fill until the pulp overflows into the vertical circulation pipe, when filtration is commenced, by gravity; or, if necessary, assisted by vacuum. At this same time the circulating pipes begin to revolve, due to the flow of pulp through them. This flow is caused by the air from the distribution pipes, which are led into the circulation pipes near the openings at the ends of the arms, forcing the pulp in the arm, out into the tank, thus producing a difference in hydrostatic pressure. Assisting to produce the revolution of the circulation pipes, is the action of the air from the nozzles of the distributing arms upon the surface of the filter bottom. The action of the air from the nozzles, which are flattened to a fish tail, serves



to maintain a clean filtering surface, practically free from settling slime, or slime deposited by suction. The nozzles are spaced as points on a spiral curve, and with the positions, every portion of the filtering surface receives a cleaning at each revolution of the arms. The flow of pulp continues with the filtration until a point is reached where the consistence of the pulp in the tank is that required for cyanide treatment, when cyanide solution is added and the water in the pulp displaced, before submitting the filtrate for precipitation of the gold and silver. As an auxiliary in thickening, decantation is practicable, by placing an inner lining about the upper rim of the treatment tank. Fresh solution is allowed to flow into the tank at the rate the filtrate leaves it, while air is constantly admitted, producing violent agitation and plentiful aeration, as already mentioned. When extraction has reached its maximum, the pulp is discharged through the valve gate in the bottom of the tank.

I have attempted here to give a statement of what this agitator is expected to accomplish. Its apparent advantages, low first cost, low cost of operation, high rate of efficiency, adaptability for use as collecting tank, and slime pulp thickener, simplicity of parts, and celerity and completeness of extraction of the gold and silver, have not at this stage been entirely proved by demonstration on an extended or a practical working scale.

PHOSPHATE DEPOSITS IN THE WEST

The availability of even low-grade phosphate rock for use as a fertilizer gives importance to the enormous phosphate deposits in Idaho, Wyoming, and Utah, many of which are on government land. The total area of public phosphate lands now withheld from entry is more than two and a half million acres. Portions of the lands thus withdrawn were examined in 1909 by geologists of the United States Geological Survey, whose reports have just been published as an advance chapter of the Survey's Bulletin 430, numbered Bulletin 430-H. This chapter includes two reports, one on deposits in southeastern Idaho and adjacent parts of Wyoming and Utah, by H. S. Gale and R. W. Richards, the other on deposits near Ogden, Utah, by Eliot Blackwelder. The reports discuss the geologic age and relations of the deposits, their origin and chemical composition of the rock, and are illustrated by maps and geologic sections. The phosphate rock is chiefly of oolitic structure, that is, it consists of masses of round grains closely cemented together with other materials, generally calcite. These grains differ greatly in size in each mass of rock, ranging from microscopic pellets to pebble-like bodies half an inch in diameter. Chips of shells and small fragments of plants are in places included in the rock. The rock at different places differs in color, ranging from gray to jet black, the darker shades being probably due to the presence of bituminous matter. Bulletin 430-H may be obtained without charge by applying to the Director of the Geological Survey at Washington. This bulletin is a part of annual contributions to Economic Geology for 1909.

Air Lift Pumping

By Edward A. Rix

*It is still a popular fancy that air in lifting fluids from depths acts in a great measure on an ejector principle and all sorts of nozzles and cones are designed to take advantage of this supposed action of compressed air, but it is all much simpler than that, and the basis of the lift action of air lies in the fact that the discharge pipe contains a mixture of air and water which weighs less than the solid water and which surrounds the discharge pipe; consequently the heavier surrounding water pushes the enclosed lighter mixture upward causing the phenomena known as 'air lift pumping.'

Most pumping experiments by this method lie within the limits of 125 ft., consequently the commercial tables, curves and data in general have been calculated for such conditions, and these will be helpful in consideration of deep well pumping.

In discussing air lifts certain general terms are used and must be understood. By lift is meant distance from the surface of the liquid being pumped to the point of its discharge. By submergence is meant the depth of the discharge pipe under the surface of the liquid being pumped. By percentage of submergence is meant the ratio of the length of the submerged portion of the pipe to the total length of the discharge pipe. The total length of the discharge pipe will of course be the lift plus the submergence. For example, if the surface of the water be 100 ft. below the point of discharge this would be called a lift of 100 ft.; if the discharge pipe extends below the surface of the water 150 ft. it would be called submergence of 150 ft., the total length of the discharge pipe would then be 250 ft. and the submergence would be called 60%. If there be a given ascertained percentage of submergence the actual submergence may be ascertained by multiplying the lift by the percentage of submergence and dividing this product by one hundred minus the percentage of submergence, expressed as follows:

$$\text{Submergence} = \frac{\text{Lift} \times \text{per cent of submergence}}{\text{100 per cent} - \text{per cent of submergence}}$$

Thus in the above example,

$$\frac{100 \times 60}{100 - 60} \text{ or } \frac{6000}{40} = 150 \text{ submergence}$$

From the beginning of air-lift experience it was assumed that the most economical condition for air-lift pumping was when the submergence was 60%, but recent developments have somewhat shaken this idea and it is doubtful whether there has been enough of accumulated data collected on this subject to make any definite statements.

The first formula used for determining the amount of free air required to do pumping, assuming 60% submergence, was as follows:

$$\text{Quantity of free air required} = \frac{\text{Gallons and lift}}{125}$$

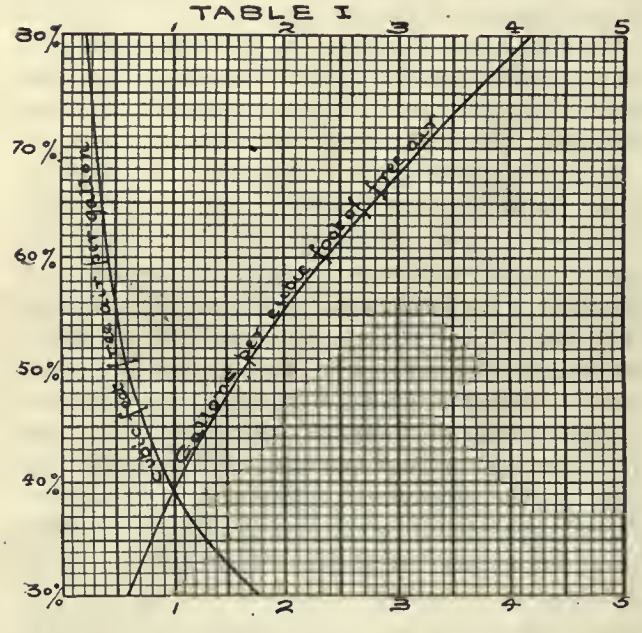
This is a rough rule which still holds good for small lifts, up to 100 ft., but it is too generous for deeper pumping. For example, if it be desired to know the

*Abstract from *The Oil Industry*.

amount of free air required to pump 100 gal. per minute 125 ft. high the result would be:

$$\text{Quantity} = \frac{125}{100 \times 125} = 100 \text{ cubic feet}$$

of free air, and the pressure required would always be measured by the submergence; thus in the above problem the lift being 125 ft. and the submergence 60%, the submergence would be 1½ times the lift or 187 ft., and the working pressure would be that due to 187 ft. Strictly speaking this would be about 80 lb., but inasmuch as there is pipe friction to be considered it is safe to take this pressure in pounds equal to one-half the submergence, thus one-half of 187 is 93½ lb., which would be a safe working pressure for such conditions.



When compressed air is introduced in the well in a finely divided state so that the bubbles are small and evenly distributed throughout most of the water the best results are produced. It is evident that if the air pipe merely discharges the air into the water with the full opening of the pipe the result will be large bubbles instead of the finely divided condition which is desired. This has led to the construction of many different patterns of what are called 'pump heads,' which is another name for the extremity of the compressed-air pipe fashioned in such a manner as to distribute the air to the best advantage to the water being pumped.

The Indiana Air-Lift Co. issues an interesting diagram, which I have marked table No. 1, and the table of dimensions which I have marked table No. 2. These may be considered fairly accurate at the lifts from 10 to 125 feet.

With these two tables it is easy to determine all the elements of an ordinary air-lift installation for pumping water. Having determined the percentage of submergence by dividing the submergenee by the submergence and lift—let us say it was 50%, look along the left hand edge of table No. 1 and find 50% and follow along to the right until it intersects the second curve and you will have the value 1.65 which means that at that submergence one cubic foot of free air will lift 1.65 gal. of water.

TABLE II.
Capacities of Air Lift Pumps

Air Pipe	Size Pump	70%	65%	60%	50%	40%	33%	Size of Well
⅜	1	15	10	10	9	8	6	2½
½	1¼	30	15	15	13	10	8	3
¾	1½	40	25	25	22	15	10	3¼
¾	2	75	55	45	40	30	20	4
1	2½	100	80	75	65	50	30	4¾
1	3	200	120	110	95	70	50	5⅞
1	3½	225	150	150	125	90	70	6
1	4	350	200	200	170	125	90	6⅝
1¼	4½	450	275	250	210	170	120	7⅝
1¼	5	550	350	320	260	200	150	8
1½	6	800	500	450	380	300	200	9⅝
1½	7	1200	750	650	550	425	300	10⅝
2	8	1700	1000	800	675	525	400	11⅝
2	9	2000	1250	1050	900	700	500	13
2	10	2500	1600	1300	1100	900	600	14

Table No. 2 gives the proper sizes of the Indiana pump heads and the proper sizes of water and air pipes for any given condition. Following up the previous problem of 50% submergence, if it be wished to deliver 125 gal. of water per minute the 50% column should be followed down to 125 gallons, then on the second column will be found the size of the Indiana pump head, namely 3½ inches.

TABLE NO. III.
APPROXIMATE CUBIC FEET OF FREE AIR AND WORKING PRESSURE REQUIRED TO RAISE ONE GALLON OF WATER BY AIR LIFT.

which is also the size of the discharge pipe. On the first column will be found the size of the air pipe, 1 in., and on the extreme right hand column will be found the smallest size well that will contain the outfit; namely 6 inches.

It will be noted that no mention is made of the lift, because the table being intended for ordinary conditions of 125 ft. or less, it has been assumed that it takes the same number of cubic feet of free air to lift 10 gal. with 60 ft. submergence as 10 gal. lifted 80 ft. with 120 ft. submergence, the working pressure only changing, in the former case being 20 lb. and the latter 40. Now this assumption is not exactly true, but within the practical limits of these lifts it is near enough to be a good convenient rule. When more accuracy is required for greater depths table No. 3, calculated by George H. Reichard, is valuable, as it takes into consideration the expansion of the air bubbles on their way from the lower depths to the surface.

The reason these expansions must be taken into consideration is evident from the very nature of the action of the air lift. Inasmuch as the action of the air lift depends upon an emulsion of air and water, which mixture is lighter than water, it is evident that a perfect condition would be where the bubbles, when introduced at the bottom of the well would maintain the same size in their passage to the discharge. It will readily be seen, however, that inasmuch as the pressure is relieved from the air bubbles as they rise toward the surface, the bubbles get larger and larger, the proportion of air to water increases exactly in proportion to the expansion and this decreases the efficiency of the lift.

The quantity of air given in this table, No. 3, is 2½ times the theoretical quantity required to do the work. Two and one-half has been selected as a co-efficient in this matter as a result of experience. Some engineers have advocated the use of 3 and even 3½ as a co-efficient, but I believe that the table as given to be approximately correct. In the first line of the table the percentage of submergence is given; also the ratio of the submergence to the lift. After having determined the amount of free air necessary to do the pumping and the pressure required, then

TABLE NO IV.
Brake Horse Power to Compress 10 Cubic Feet Free Air Per Minute.

120	2.07	1000	4.32	

by reference to table No. 4 the brake horse-power to compress the air may be determined. This table shows the actual horse-power necessary to compress 10 cu. ft. of free air per minute to the pressure mentioned. An allowance is made in this table for friction and other losses of power, and is generous enough to allow an ample amount of power to do the work.

OLD TIMES AND THE NEW

As compared with a modern California gold mill, with its heavy stamps, rapid drop, low discharge, massive mortars, and concrete foundations, the following description of the 40-stamp mill of Hayward's Eureka mine at Sutter Creek, Amador county, California, as it was in 1866, is interesting. The mortars had heavy cast-iron bases (4 in. thick), with low trough, and the upper portion of wood. The stamps weighed 450 lb. when newly shod, and dropped 11 in. 80 times a minute. The shoes and dies were 7 in. diam., and both were used until completely worn out. They were of cast iron and lasted from four to six weeks. The discharge was 11 in. above the top of the dies when the latter were new, and this distance increased as the stamp wore down. The mortars discharged on one side only, as they generally do now, and the screen opening was about 46 in. long and but 2 in. high. No. 11 Russia iron slotted screens were used, and these were provided with vertical slots ½ in. long. The screens were reversed when the lower edge was worn. The amalgamation was entirely accomplished inside the mortars, the gold being caught on a copper plate 4 in. wide, situated just below the screen—what would be equivalent to the modern chuck-block. On this plate the gold collected in cakes which were broken off in chunks by means of chisels. Under the screen no outside copper plate was employed, the pulp falling on a rough pine board, which was thought to afford a better index of the condition of things inside the battery than a copper plate would. This idea Mr. Hayward maintained to the end, and in all of his mills the rough pine board was always found immediately beneath the iron lip of the mortar. There is no doubt that the idea is an excellent one, as it is a fact that the board is as good an indicator of the condition of the amalgam inside as can be found. All of the early stamp-mills of California were not of this type, for at the Eureka mill at Grass Valley, there were 20 stamps of 815 lb. each; the Allison Ranch mill, below Grass Valley, had 12 stamps of 1000 lb., and the Rocky Bar mill, also in Nevada county, was equipped with 16 stamps weighing 1025 lb. each.

The tendency today is toward heavier and still heavier stamps and the crushing of large tonnage. This is a natural outcome of the development of large mines upon ores so low in grade that to secure a profit everything must be done upon a great scale. Mining methods have been introduced which make the mining of huge orebodies inexpensive. Transportation has been reduced to a science both under and above ground, and the mills are crushing from 5 to 10 tons per stamp daily, where formerly but 2 to 3 tons was considered the daily duty of the stamp.

In retorting amalgam the lower end of the discharge pipe must not project beneath the surface of water in the pot set to receive the re-condensed mercury, as an explosion may result. A wet cloth should be wrapped about the pipe and this may be allowed to extend down into the water.

Gold Mining in Randsburg Qurdrangle, California

By Frank L. Hess

*The Randsburg quadrangle is included between 35° 15′ and 35° 30′ north latitude and 117° 30′ and 117° 45′ west longitude. The town of Johannesburg is almost in the centre of the quadrangle, and Randsburg lies a mile west. Johannesburg is at the end of a branch of the Santa Fe railway which joins the main line at Kramer, 28 miles south. The town is 90 miles north and 30 miles east of Los Angeles. The area is part of the Mohave desert and has an arid climate. The country is dry, vegetation is scanty, and if a water level exists it has been found only in the basins into which the short periodic streams flow. To judge from the topography of the country, a similar climate has been in existence here through a considerable length of time, for the present erosional forms have probably been shaped largely by weathering agencies similar to those now observed.

The variation in altitude in the quadrangle amounts to about 3000 ft. The lowest altitude, a little less than 2300 ft. above sea-level. The highest point, Red mountain, 5270 feet above the sea, is two or three miles southeast of the centre.

There are three mountain masses ordinarily referred to as the Rand mountains, the Lava mountains, and the El Paso mountains, from which the Summit range extends easterly.

The Rand mountains rise with a gentle slope from the southeast almost or quite to the summit; but on the northwest side they drop steeply to the valley, which is 500 to 1000 ft. lower than points on the southeast side that are equally distant from the crest. Randsburg is situated in a valley in the Rand mountains, three miles from the northeast end. Johannesburg is in a cut through the range, one mile east and a little north of Randsburg. Beyond Johannesburg the mountains do not stand so high above the surrounding country. Nearly all the gold mines of the area, except some small placer mines, are in this range or in a spur from it.

The Lava mountains include the highest peak of the area, Red mountain. Altogether they cover about 50 square miles.

Faults.—A prominent fault follows the south face of the El Paso mountains and crosses them about the middle of the quadrangle on the Kern-San Bernardino county line. The scarp of the fault can be seen from the south for many miles. It can be readily followed west of the quadrangle for a number of miles, and on the east it can be seen cutting across the end of the Slate range, 20 or 25 miles away. At Garlock, two miles west of the quadrangle, a large alluvial fan cut through by the fault shows a face 280 ft. high. Just within the quadrangle, near its western boundary, are two large depressions formed by the subsidence of the surface along the fault. One is a quarter of a mile long, 600 ft. wide, and 75 ft. deep, and the other, half a mile east, is over a mile long, a quarter of a mile wide, and 50 to 125 ft. deep. These blocks have dropped in comparatively recent years, though men who were in the country as early as 1863 state that the sinks were there at that time.

Geology.—The rocks of the quadrangle show considerable variety, but though two or three of the igneous rocks have rather exceptional structure there are no remarkably unusual types. Granite occupies the surface of nearly one-half of the quadrangle.

Granites.—There are two main granite areas, one being a broad, wedge-shaped area in the south end of the quadrangle, with the apex 2½ miles south of Johannesburg, and another extending from the Summit range northward east of El Paso peak to the edge of the quadrangle. There is also an intrusive granite which cuts across the Rand mountains on the south side of Randsburg. It is four miles long and one-half mile wide, forming four of the more prominent peaks. A part of this intrusion is much mixed with schist. This intrusive mass is probably younger than the large mass to the south, for the latter seems to be under and may be older than the schists of the Rand mountains, whereas the granitic intrusion near Randsburg cuts the schist and probably the granite on the south. It has many phases and in places is basic. The granite at Randsburg was not all intruded at one time, but the periods between the successive intrusions were short, geologically. During the same period of time in which the granite was intruded many narrow porphyritic dikes of various compositions and textures were intruded. Some of the more acidic ones cut the granites and diabase dikes. In other places they are cut by the granite and by the diabase.

Sedimentary Rocks.—The sedimentary rocks include the schists of the Rand mountains, the less altered rocks in the northwestern corner of the quadrangle, and a much younger series of poorly consolidated sandstones and clays which crop out from under the lavas and which are also found at Summit Diggings and near the northwest corner of the quadrangle. The rocks of the Rand mountains are mostly schists with minor interbedded quartzites and greatly altered limestones.

On the southeast side of the mountains and around Randsburg and Johannesburg the schists are thinly fissile and of a dull-gray color. They may be classed as mica-albite schists. Little is known of the age of the schists, and no schists similar to those of the Rand mountains are known within many miles in any direction. The sediments in the northwest part of the quadrangle consist of quartzite, mostly fine grained, but with a few beds of coarser material; silicious shales; and limestones, most of which contain a considerable amount of impurities. The limestones contain much chert and in places are so silicious that little calcium carbonate is to be seen.

Lavas.—The lavas are largely andesites, with some basalt, but include more acidic varieties, rhyolite, and probably latite and dacite. There is some obsidian among them. Five miles northeast of Johannesburg fragments of the coarse basal part of the schists are included in the lava, showing that it must

*Abstract from Bull. 430-A, U. S. Geol. Surv., 1909.

have broken through, including these fragments.

Fragmental Deposits.—The fragmental deposits, such as sand and gravel, cover considerable areas. About two miles east of St. Elmo a shaft was sunk 250 ft. without striking bedrock. In a low range of hills two miles north of Randsburg, in the small valleys tributary to the large one, shafts have been sunk more than 100 ft. without striking bedrock, though it shows in the low hills on either side. Small valleys have been entirely filled and the hills on either side covered. At Goler the gravels are at least 800 ft. deep, as shown by wells drilled by the Yellow Aster Mining Co. On the north side of the valley between Randsburg and Goler there is a large accumulation of débris, forming hills 350 ft. high. They extend half way across the quadrangle to Summit Diggings. In them is a great quantity of lava boulders, remnants of flows from Black mountain, a few miles west of the north end of the quadrangle. Only a small area of gravels, at Summit Diggings, are of economic importance.

History and Condition of Mining.—Gold was discovered in Goler Wash, nine miles northwest of Randsburg in the winter of 1893-94. Dry-washing camps soon sprang up there and in Last Chance canyon, Red Rock canyon, and Summit Diggings. The site of the last-named camp is in the quadrangle. In 1895 the Yellow Aster mine was discovered by C. A. Burcham, John Singleton, and Fred Mooers, and other discoveries quickly followed. A railroad was soon constructed from Kramer, on the Santa Fe railway, to Johannesburg, and water was piped from wells six to eight miles distant.

The mines, including the dry placers, have probably produced between $9,000,000 and $10,000,000, of which the Yellow Aster mine has taken out about $6,000,000. A number of the smaller mines are worked by the leasing system, paying from 10 to 25% royalty, generally after deducting milling charges, but sometimes gross. Besides the Yellow Aster's stamp-mills, with 100 and 30 stamps, there are the Phoenix, 6 stamps; Red Dog, 10 stamps; Sunshine, 3 stamps; Ostick & Renne, 3 stamps; Blackhawk, 10 stamps; and Little Butte, 2 stamps. The last two are not operated. All of these work on custom ores except the Yellow Aster and Sunshine mills, which work only ores from their own mines. The Atolia Mining Co. has a 5-ft. Huntington mill which is used only upon tungsten ore (scheelite). In what is known as the Rademacher district, which includes El Paso peaks, Laurel mountain, and the adjacent country on the north, considerable prospecting has been done for a number of years and a little is still carried on, but there has been no output.

Gold Deposits.—Most of the gold deposits of the quadrangle lie in the schist area, along the Rand mountains, reaching their greatest development in the Yellow Aster mine at a place where a granitic intrusion crosses the axis of the range. Along both sides of the range, southwest from Randsburg, are other gold deposits, but those on the northwest side of the range have so far produced very little ore. On the southeast side a number of mines have been and are being profitably worked. There are also a number of mines in the schists within a radius of 1½ miles north and east of Randsburg. Outside of the schists of the Rand mountains the St. Elmo mine, in the granite 5½ miles southeast of Randsburg, has produced some gold. Six miles northeast of Randsburg, at Summit Diggings, a few thousand dollars has been taken from gravels in the sandstones surrounding an intrusive mass of hypersthene-hornblende andesite which has locally metamorphosed the sandstone into quartzite. No veins have been found in the vicinity. Scheelite occurs in small amount with the gold ores in a number of the mines in the Rand mountains, and a mile north of St. Elmo, at Atolia, are mines which are probably working the largest and purest scheelite deposits known.

Yellow Aster Mine.—The Yellow Aster was the first lode gold mine discovered in the quadrangle, and for ten years it has been one of the largest gold producers in California. It is at the head of a gulch where a crescent-shaped mass of granite cuts across the mountains. The principal level of the underground workings, known as the Rand level, is 500 ft. below the top of the mountain. The glory hole, from which practically all of the ore mined was being taken at the end of 1909, opens from the gulch 115 ft. above the Rand level. The granite is intrusive in the schists and occurs in many dikes, which show a close relationship petrographically, though there is a wide difference in their general appearance as casually examined, owing to their varying degrees of decay and alteration. The granite in the mine carries biotite and is fine textured. In places the biotite forms irregular segregations from one-fourth to two inches diameter. The feldspars are white, buff, and pink, and in some places where the granite is fine grained there are porphyritic white orthoclase feldspar crystals one-eighth to one-fourth inch in thickness. In places some hornblende has evidently been contained in the granite, its former presence being indicated by aggregations of small particles of magnetite whose general outline corresponds to a cross-section of hornblende. There are also porphyry dikes cutting both granite and schist, but they are older than the orebodies, which pass through them. Where found in the mine, the granite-porphyries are light colored and show little or no mica or hornblende, though it is probable that the lack of biotite is due to its decomposition. The groundmass is of fine-grained orthoclase. The phenocrysts are of microcline and orthoclase with here and there a small quantity of lime feldspar. The granite masses range in thickness from a few inches to several hundred feet. They are evidently branches from a larger body and may come together below. The prevailing dip of the schists on the top of the mountain is nearly flat, but locally the schists lie at all angles and dip in many directions. Similar variations of dip and strike are seen in the mine. The schist is thinly fissile except near the larger granite masses, where it is locally so compact that it is difficult to distinguish from a dark granite. There is a noticeable absence of visible quartz in the mine. The schists contain lenses of white barren quartz.

(To be Continued.)

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Decrease of Value in Ore-Shoots with Depth

The Editor:

Sir—Referring to Oscar H. Hershey's letter on the 'Deerease of Value in Ore-Shoots with Depth,' published in your issue of July 16, 1910, and to J. Parke Channing's remarks upon the same subjeet in the issue of September 24, 1910. This tendeney of mineral veins to deerease in value is well recognized, but has been too often assumed to be a rule. Like the theory of seeondary enriehment, it is a hard-ridden hobby of some geologists who, like the rest of mankind, are prone to get ideas in their heads, then try to make nature eonform to them. It seems to me as a general thing no one theory accounts for the evolution and development of any elass of ore deposits; they are the eumulative result of more than one, perhaps many, diverse forees aeting in different ways. There is no reason to suppose ore deposits may not extend as deep as the roeks are fraetured, sinee, exeept in eases of magmatie segregation, a vein must have a void in whieh to form, and there must be fractures or fissures to provide ehannels for the eireulation of the metal-bearing solutions. Capillary diffusion, or eireulation, of sueh solutions is probably not an important factor, although one by no means to be ignored. One of the notable features of the day is the constantly reeurring reports of diseoveries of rieh ore at relatively great depths, depths in some eases far beyond regions previously assumed to be unproduetive. This inerease of depth doetrine is a favorite one with the promoter and faker, hence the conseientious mining engineer cannot be blamed if he be somewhat shy of it; moreover, ore deposits usually have not been found by experienee to inerease in value with depth beyond the first thousand feet, or thereabout. There are, however, as Mr. Channing observes, exeeptions to this rule, the known number of whieh is becoming more and more numerous. Supposedly exhausted mining distriets often exhibit a wonderful vitality, as, for example, Leadville, Colorado. Sueh facts are indisputable, however mueh they may be distorted and magnified in tempting an innocent and perverse publie to invest in worthless and exhausted properties. By perverse I mean those people who will not employ skillful and honest advisers to examine a property before risking their money in it. This trait seems peeuliarly notable in the Ameriean publie, probably due to its gambling spirit; a propensity that throws common sense to the winds and trusts that miraeles will happen! However, this is a dangerous and profitless theme and aside from my subjeet, for I have long since learned there are many thousands of people who appear to enjoy losing their money in erazy sehemes and no amount of preaehing will eonvinee them that mining and eeonomie geology are highly speeialized teehnieal arts whieh may be learned only by years of careful study and experienee, and even then, unless applied by level-headed men with practical instinets may lead to wrong eonelusions. To anyone interested in the subjeet, I can commend among the many excellent publieations upon the subjeet, a paper reeently issued by R. A. F. Penrose, Jr., upon 'Some Causes of Ore-Shoots' (Economie Geology, Vol. V, Mareh 1910). While the facts and observations in this paper are not pretended to be especially new, the deductions from them strike me as being of great value. Thus, upon the subjeet of 'Deep-Seated Alteration,' Mr. Penrose says: "While superfieial influenees are altering the upper parts of an ore deposit, deep-seated influenees may also be active below. The repeated longitudinal fissuring of a deposit after its formation, * * * may afford new ehannels for the eirculation of new ore-bearing solutions from below, and these may profoundly affeet the deposit. They may form new ore in new openings, or add to the ore already existing, or perhaps segregate ore formerly disseminated, in all of whieh eases ore-shoots may result. Where large bodies of sulphide ores existed in the original deposit, these may be greatly inereased by their preeipitating action on the new ore-bearing solutions. The new solutions may sometimes earry different metalliferous materials from the older solutions that formed the original deposit, and may thus form new shoots of different ores. * * * In all these processes, however, the result is not always an increase of value or volume of ore, and, as with most faetors which influence ore-shoots, there may be no effect at all, or there may be an aetual diminution of ore. For instanee, when the longitudinal movement along a fissure oeeurs at only more or less remote intervals, deposition of ore may be increased as just deseribed, but when the movement is very frequent or almost eontinuous, it is likely to retard deposition or even to prevent it, for deposition progresses best during intervals of repose after dynamic movements. This may be a eause of the faet observed in some mining regions, though by no means in all, that the ore deposits oeeur in the smaller fissures and not in those that have been the seenes of the greatest amount of movement."

In the eoncluding paragraphs Mr. Penrose remarks, and I am sure we will all agree with him: "More financially disastrous mistakes have probably been made in mining by supposing that beeause eertain conditions hold good in one region, they must hold good in another, than from any other eause. Every distriet is a law unto itself in the localization of its ore in shoots, and no distriet can be properly understood until it has been thoroughly studied *per se*. On the other hand, shoots are not one of those obseure and mysterious phenomena whieh bafile all efforts at explanation. They are simply the result of natural causes whieh have been, and are sometimes even yet, active. In almost any distriet where suffieient mining has been done to permit a thorough examination of the ore deposits, some sort of an idea of the probable eause of the ore-shoot should be obtainable."

It must ever be borne in mind that in the majority of cases ore deposition on a sufficiently large scale to be economically productive, is essentially a superficial or vadose process, the depth depending upon the ground-water circulation, which varies greatly within relatively narrow limits, and has often fluctuated from time to time during the geologic history of any one particular district. The fact of this varied history and genesis cannot be too strongly emphasized. Generally speaking, to no one force or phenomenon can the origin of any one deposit be traced; it is the result of many, acting either simultaneously or in succession. It is difficult in most cases to say where the so-called vadose deposition ceases and something else begins; it seems probable this superficial circulation is often deeper than generally suspected.

F. Lynwood Garrison.

Philadelphia, October 5.

A Tip on Formation

The Editor:

Sir—What is the best formation for copper deposits; some tell me one thing and some another. One miner of large experience—mostly at Butte, Montana, I think—says 'granite' is the thing. Another fellow says 'andesite.' and a third thinks there is nothing equal to 'porphyry' as a copper formation. If there is any real difference I should like to be informed.

Prospector.

Douglas, Arizona, October 8.

[The formation makes little difference. Prospectors are likely to overlook something of value if they spend their time in searching for some particular formation, such, for instance, as they have been familiar with in other camps. At present monzonite porphyry is considered the best possible formation for copper ores, for the reason that great mines have of late years been developed in that rock, at Bingham, Utah, Ely, Nevada, and elsewhere. The famous mines of Bisbee are, in part at least, in limestone; the Lake Superior mines in amygdaloidal beds and in conglomerate. The Ducktown copper mines of Tennessee are in schist, as are also the famous deposits of Mount Lyell, Tasmania. Many mines now producing copper were in their early history either gold or silver mines. The great mine of the Mountain Copper Co., Shasta county, California, was originally worked as a silver mine, and was at one time equipped with a stamp-mill. The mines of Cerro de Pasco, Peru, were worked many decades for silver. It is only within the past few years that their value as copper producers has been recognized. The lead-silver vein of Broken Hill, New South Wales, Australia, is now producing copper from the lower levels. The formation is schist. The Mount Morgan in Queensland, Australia, has always been considered a gold mine, but it also is now producing copper ore in depth. Many of the large copper deposits of northern Mexico are in andesite. In consideration of these facts we must conclude that copper, like gold, is 'where you find it.'—Editor.]

A Question in Converting

The Editor:

Sir—With all the improvements that have been made in the handling of large copper properties and the smelting of the ore, or concentrate, little has been done in converter practice other than 'rule of thumb' in determining the depth of the tuyeres below the surface of the matte that gives the highest efficiency for the air blown through the mass. Converting costs are high largely on account of the cost of compressing air to the pressure necessary to overcome the weight of the copper at the tuyeres. Could this head be reduced, blowing costs would be lowered and conversion costs decreased proportionally. There is no doubt that much of the air passes through the matte without its oxygen being utilized, which therefore means a direct loss. I do not believe any scientific work has been done to determine this amount of waste oxygen which so influences the cost sheet. Several attempts have been made to build reverberatories that would both matte and convert the ore in one operation, but these have so far been unsuccessful. Many of the larger companies are now experimenting with the basic lined converter, supplying the necessary silica with the charge rather than having it abstracted from the converter lining and this bids fair to make a slight reduction in operating expenses, but still there is that lack of information on the vital question of the utilization of all the oxygen of all the air that goes into the converter. The companies which are in a financial position to experiment are mostly paying substantial dividends and either do not feel the need of experimenting or do not care to keep up the expense of research work, and the companies that are in need of information of this sort are not in a financial position to carry on the necessarily expensive experiments. If any one of your readers know of any literature on this subject I should be pleased to hear from him.

Converter.

Berkeley, California, October 10.

[Our correspondent has raised an interesting and important question. No literature that has come to our notice discusses the matter of depth of tuyeres in converters.—Editor.]

Inhalation of Mineral Dust

The Editor:

Sir—Will some of the many readers of the *Mining and Scientific Press* tell me why it is that the dust from machine drills in dry mines is so quickly fatal to the drill runners, while men may work in dry-crushing mills where the atmosphere is constantly laden with fine dust for years and apparently suffer no evil consequences? I have noticed this fact many times but could never quite satisfy myself as to the very noticeable difference in the effect on the men, for as far as one could judge from appearances, the mill men have much the worst of it, living 8 to 10 hours a day in a cloud of dust so thick that objects 50 feet distant are often invisible.

Drill Runner.

Tuolumne, California, September 24.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

It is good business to have an extra cam-shaft with cams in place in every stamp-mill. It saves much time when one is needed.

Potassium chlorate blasting powders are not new. Moreover, they are extremely dangerous, but withall less effective than nitro powders.

The highest speed that may be safely attained in dropping stamps of the gravity type without 'camming' is about 110. In order to do this the cams must be short and the drop not exceed 5 inches.

The loss of mercury in stamp-milling varies greatly under the differing conditions. Some mill-men consider the loss of 0.1 oz. per ton of ore stamped as excessive, while others think this loss small.

Incandescent electric lights are a cheaper means of illumination in most places around mines and mills, than candles, after the first cost of installation. They are also far more safe, being less likely to cause a fire.

Steel passenger coaches of standard gauge and make weigh 118,500 lb. as compared with 85,000 lb. the weight of the standard vestibuled coach. The steel coaches are found to be far better able to resist the effects of accidents and are less likely to take fire in the event of a wreck.

All steel shapes for structural purposes are made after the specifications of the Association of American Steel Manufacturers when not otherwise specified. To supplement these structural steel standard specifications the association has just adopted by letter ballot a standard specification for reinforcing rods for concrete.

Fine grinding is accomplished in Huntington, Chile, and tube-mills of various design and there appears to be some difference of opinion among mill-men as to which machine produces the most satisfactory results. The tube-mill possesses the advantage of making less iron particles by abrasion than the other types of machine.

The dynamite contract for the Panama Canal for the fiscal year 1911 was awarded to the Du Pont de Nemours Powder Co., the amounts and prices being as follows: 45%—8,540,000 lb., at 11.7c.; 60%—5,187,000 lb., at 12.7c. The amounts quoted are estimated as the possible requirements for the fiscal year, but not more than 50% of the estimated amount need be purchased.

Copper in gneiss is by no means an uncommon occurrence. By gneiss is meant rocks of the composition of granite which have a sheeted or laminated structure. Some of the copper mines of the Alleghany mountains are in gneiss. Copper ores occur in gneiss in Gilpin county, Colorado, and elsewhere. Some of the granites and monzonites in which copper occurs abundantly are gneissoid in part.

The speed of winding in mine shafts varies all the way form 100 or 200 ft. per minute to upward of 6000 ft. In small mines the speed usually is about 400 to 500 ft. It is only in the great deep mines that high maximum speeds are attained, and not in all of these. It is considered unsafe to run with men at greater speed than 800 ft. per minute. At such speed the engineer can have the machinery under perfect control.

Pumping by means of windmills is the most economical method of lifting water, but it possesses the disadvantage of sometimes being unavailable when most required by reason of lack of sufficient wind. Where large tanks are provided there is greater assurance of having a supply of water when it is needed than where the storage capacity is small. At some salt-making plants windmills are utilized to pump brine from one basin to another. So far as known windmills have not been successfully employed as a means of power to operate even small quartz mills.

Escape of cyanide solution from the mill is usually confined to that remaining as moisture in the discharged tailing, and that is usually so reduced by the addition of fresh water in sluicing out as to render the solution harmless. In desert regions some danger may arise from solution thus discharged becoming strengthened by evaporation. Where this is the case it would be well wherever possible to collect the water by impounding the tailing, and fencing the pond to keep stock from drinking it. The water in the pond could be pumped back to tanks for re-use in the mill.

The Sargasso Sea owes its existence to the great ocean rivers that encircle it. It is like a vast lake in the centre of the Atlantic, but one whose shores are ever-moving waters instead of stable land. It is like the calm centre of an immense whirlpool. The far-off deep-sea currents that sweep around its circumference do not disturb the stagnant waters within its boundaries. These weed-covered waters are forever placid, except at rare intervals when some vagrant storm swoops down from the heavens and ruffles their surface. The atmosphere above is usually as calm as the seas below. The great rivers of the air, the trade-winds, pass this region by.

To insure the estimated results of engineers in constructing the Hudson River tunnels of the Pennsylvania railroad, a cement-testing laboratory was established at the Manhattan shaft offices, under the charge of a cement inspector who was furnished with assistants for sampling, shipping, and testing cement. All materials used on the work, such as bricks, sand, stone, waterproofing, etc., were tested here, with the exception of metals, which were under the charge of a metal inspector reporting directly to the head office. This department cost about $10,000 for salaries and $3000 for apparatus and supplies, or about $13,000 in all. There were 800,000 bbl. of cement tested, and samples from 2,100,000 bricks.

Special Correspondence

FAIRBANKS, ALASKA

Local Interest in Quartz Development.—Encouraging Ore Showings.—New Machinery.

A significant event in the development around Fairbanks was the excursion taken by a body of business men last Sunday around the creeks to visit and investigate the different quartz properties. Whereas the business men up to date have condemned the lode mines, the party that tramped the hills last Sunday and picked specimens from the several dumps was fully convinced of the oft-repeated assertion that for the amount of work done, no camp has shown better surface prospects.

An 18-month lease has been taken recently on the Whitman & Murray mine in Skoogy gulch. This mine has a 150-ft. cross-cut into the hill with about 100 ft. of drifts along the vein. There is also a 50-ft. winze near the end of the cross-cut, but water has caused a temporary abandonment of same. A lower adit is now being driven to drain this winze. The ore from this mine has been milled in Scrafford's arrastre, showing about $40 per ton gross. At the head of Fairbanks creek, McCarty, Zimmerman & Lawson have just opened an exceptionally wide pay-shoot on their vein. While not assaying as high as the narrower parts of the vein, it is understood that the showing is entirely satisfactory, and the opening of the ore at this point proves the continuity of the vein for a thousand feet. The Jackson shaft on Cleary summit is down 30 ft., and a good sized body of galena ore is exposed in the bottom. The recent discoveries made by the Cook brothers on the left limit of Fairbanks creek just below the tributary called Too Much Gold creek are showing up as well as the best in the short time they have been opened. The shaft is down only 15 ft., but two assays made on the ore showed $94 and $123 per ton respectively. The vein was 30 in. wide where uncovered, but pinched at the frost-line, again widening out when the line of permanent frost was passed. Practically all the veins uncovered in this district show this pinching, and it is generally accepted that it is due to the surface movements caused by change in frost-line. Another vein uncovered by the Cook brothers is two feet wide between well defined walls. The gold here is much finer than in most of the other veins so far discovered, but the value is more even. Hardly a piece of ore can be selected that will not show pay when crushed and panned. Above the Cook brothers, August Hess has uncovered a vein two feet wide that shows free gold in numerous specimens.

After a summer of idleness, the Rhoads-Hall property is again being opened. An air shaft will be sunk and further driving done till the end line of the claim is reached. The main adit is already in 600 ft. and bad air caused the temporary shut-down. Just below this property in the creek bed, Mike Stepovich has just made a clean-up. The moss was removed with mattocks and the quartz float sacked and shipped. In all, 2½ tons was sacked which yielded a $700 bar. Willow creek is at present producing ore at two properties. Buell & Phipps are sacking quartz at the head of the creek from a rich vein, and the Tolovana Mining Co. is storing ore from development. The lease taken by George and Ed Thomas on the lower end of the Spaulding-Clough property and the upper end of the Wild Rose is being actively developed. The shaft is down 40 ft. and though the pay-shoot is narrow, the excellent walls hold out hope for a larger tonnage when the shaft is deeper. It it probable that after the permanent frost-line is reached the vein will be found in its original width. On the upper end of the Spaulding-Clough property a lease has just been taken by Huddleson & Co., who have heretofore been operating placers on Eldorado. A 30-hp. plant will be installed and work commenced in the 60-ft. shaft, where a 3-ft. vein of $50 ore was opened. At the same time, the owners of the claim are prospecting the vein by driving an adit from the lower end toward the shaft. What promises to be one of the largest producers in the camp is the Fredericks property at the head of Vault creek, four miles south of the Spaulding claim and still farther from the properites that first showed good ore. The shaft is down 45 ft. on a 6-ft. vein with an excellent average value. Across Vault creek and on the divide between Vault and Treasure, Hoel brothers have located a 16-ft. body of graphitic schist and quartz stringers. This lode seems to be the extension of the Fredericks, being almost in a line with the strike of the latter. F. G. Noyes has lately found a good vein on his claim at the head of Moose creek.

The Pinder concentrator for the Fairbanks test mill has arrived and is installed. In a few days the battery will be raised and the concentrator put to work saving rich concentrate hitherto wasted. Work is progressing rapidly on the 10-stamp Chena custom mill. Another month ought to see the mill in operation. Mr. Cunningham will be in charge. The mill will be complete, all pulp being classified after crushing by a Callow cone, the sand going to vanners and the slime to Deister slime tables.

TORONTO, CANADA

Cobalt Dividends.—Conditions at Kerr Lake. — Elk Lake a Promising Field.—Bullion Theft.

The Cobalt mining situation is improving, owing to favorable reports from several of the mines and the fact that dividends are well maintained. The Nipissing has declared its regular quarterly dividend of 5% with an extra dividend of 2½%. La Rose pays 2% quarterly as usual, the expectations entertained by some that the old rate would be restored this fall having been disappointed, as the directors wisely preferred to accumulate a larger cash reserve before increasing the rate. The Crown Reserve continues to yield the largest returns, paying a 6% quarterly dividend with a 9% bonus. The Right of Way has declared its regular quarterly 2%. A financial statement issued by the Nipissing has materially strengthened the market, showing a surplus on September 17 of cash and ore on the way, or at the smelter, of $1,227,000. Since June 20, the company has paid $750,000 in dividends and increased its surplus by $200,000. Recent developments at the Kerr Lake property indicate that there is little foundation for the fear that its reserves of high-grade ore were becoming depleted. Last month 165,000 oz. of the yield out of a total output of 200,000 oz. were secured from vein No. 7 at a depth of 150 ft. This level has been driven on for 300 ft., leaving 450 ft. more to be opened before the end is reached. This month several small veins branching from No. 7 are being followed. No. 8 is yielding 3000-oz. ore. The Hargraves has come to the front lately as one of the most promising of the newer enterprises. The company has found a vein, supposed to be the rich Kerr Lake vein at the 300-ft. level where it carries 6 in. of good ore. Two new surface veins have been discovered on the Badger each carrying silver. Over 6000 ft. of trenching and stripping has been done on this property during the summer. At the Temiskaming cross-cutting is being done at the 500-ft. level to catch No. 3 vein which is strong at 400 ft. The Crown Reserve will ship no more low-grade ore after October 1, but will turn it all into concentrate. Additions are being made to the Buffalo mill which will double the capacity of the cyanide department, enabling the management to reduce the cost of labor and power by one-half. Operations at Elk Lake and Gowganda are still badly handicapped on account of transportation difficulties. A new wagon-road is being built from Elk Lake to Charlton, on the Temiskaming & Northern Ontario railway, which will provide a good highway for vehicles at all seasons and relieve the situation to some extent, but at latest accounts it was doubtful if the work would be finished before winter. In the meantime only high-grade ore can profitably be shipped and there are large accumulations of low-grade ore throughout the region. Mine managers are anxious for the establishment of one or more custom concentrators. Negotiations are under way for the installation of a concentrator at Elk Lake, and the Reeves-Dobie at Gowganda is getting in concentrating machinery for

a plant of their own. The Big Six property at Elk Lake has been leased for five years by W. R. Mowery on a royalty basis. It carries large quantities of milling ore. Since work was resumed at the Bartlett mine, Gowganda, a 7-in. vein has been found at 8 ft. in a new shaft from which high-grade ore is being taken. About 30 tons of high-grade ore was recently shipped from the Gates property at Gowganda, owned by M. J. O'Brien, being teamed to Elk Lake and forwarded by steamer down the Montreal river. A party of American capitalists comprising Ambrose Monell, J. R. Lamar, and Charles L. Dennison, of New York, recently visited Porcupine and inspected the Dome mine. They found 100 men at work. The mine is equipped with a compressor, two diamond-drills, and a small mill. A large stamp-mill will be installed as soon as transportation facilities render it possible. The Nova Scotia mine, Cobalt, was recently the scene of an audacious robbery. Several of the employees broke open the concrete vault and stole silver bars ready for shipment valued at $17,500. The crime was soon traced to the perpetrators and the plunder recovered. Two of the thieves who confessed were sentenced to five and two years' imprisonment respectively. The Canadian Government's peat plant at Alfred, Ontario, has shipped several hundred tons of peat to Ottawa, where it is being placed on the market at $3.25 per ton, finding ready sale. It is expected that this experiment will act as a stimulus to private enterprises for the supplying of peat fuel. Willet G. Miller, Provincial Geologist of Ontario, has returned from attending the International Geological Congress at Stockholm, Sweden, and will shortly make another inspection of the Porcupine district.

SALT LAKE, UTAH

Utah Copper Co. Production. — Consolidation of Park City Mines. — Daly-Judge.

According to reports the September production of the Utah Copper Co. will be about 7,443,000 lb., a reduction of 1,200,000 lb. from the average of the three preceding months or about 14%. While this curtailment in production is in force work is going on toward developing for a greater production than ever as soon as the market is in better shape. Twenty-one benches have been cut in the side of the mountain at Bingham and eighteen shovels are at work. Three more shovels will be added shortly for developing the ground recently acquired from the Boston Consolidated. To secure ground for the dumping of overburden from the stripping operations the company has purchased Copper Center gulch which insures dump room for some time to come. The conversion of the gulch into a dumping site made necessary the moving of the buildings therein of the Bingham Mines Co. This company has been working its Commercial mine through the lower Commercial adit but this has been abandoned and arrangements have been made with the United States Mining Co. to use the Niagara adit. This will be extended 300 ft. to get under the Commercial orebodies and until this point is reached the mine will be closed. The new outlet brings the mine nearer the main wagon-road and it is expected that the Denver & Rio Grande will build a spur track to the Niagara as soon as shipping is resumed. The Utah Copper Co. has decided to spend about $200,000 for new locomotives to be used on the Bingham & Garfield railroad. These will be Mallet articulated compounds weighing 300 tons each. The Utah Consolidated tramway is now delivering ore to the Tooele smelter at the rate of 100 tons per hour and the plant is treating 600 tons per day of Utah Consolidated ore.

What appears to be the first step in the much talked of Park City merger has been accomplished by the consolidation of the West Quincy and the Thompson. This deal has been pending, off and on, for a number of years but has just been finally consummated. The new company will be called the Thompson-Quincy Consolidated and will have 1,250,000 shares of stock of a par value of $1. Of this issue 75,000 shares go to each of the Daly and the Ontario and 50,000 to the Daly West. In return for these payments of stock the company receives certain privileges including the right to connect its workings with those of the other companies. This means that the Thompson-Quincy will be allowed to connect with the Daly West and drain into it and thence through the Ontario tunnel. Ore will also be transported through the Daly West. It is expected that this merger will be followed shortly by one in which the Daly West will take over the Ontario and Daly properties in exchange for stock. Definite announcement as to terms has not been made and the proposition has not been submitted to the stockholders. The directors of the Daly West voted to pass the usual quarterly dividend as the production of the mine has been materially decreased while extensive development is being carried on. The mine has something less than 200,000 tons of ore proved and this is all on the lowest levels where cost of hoisting is high. The plan is under consideration of building a new mill at the mouth of the Ontario tunnel but if this is done it will probably have a capacity of 600 tons per day and the present

Map of Utah.

condition of the mine does not justify the erection of so large a plant. It is planned to develop thoroughly on the lower levels and prove up a larger tonnage before authorizing the construction of a new mill.

At the Snake Creek tunnel of the Daly-Judge the new ventilating system has been installed and the gasoline locomotive is in use so that the third shift, which was taken off when the air got bad, has been reinstated. The contractors expect to make at least 12 ft. per day from now on. At the mine the Starret pump has unwatered the 1600-ft. level which was submerged for twelve years and ore is now being mined here although all of the workings have not been cleared as yet. It is on this level that the contact occurs between the lime and the quartzite, the formation which has yielded the best ore of the Park City district. The Mammoth was temporarily closed for a few days while some repairs were made to the main working shaft. The material for the repair of the hoisting plant which was seriously damaged about three months ago by a runaway, is on the ground and repairs will be rushed as fast as possible. At the Eagle & Blue Bell the new hoist has been put in operation and only about 85 ft. of sinking remains before the main shaft is connected with the 1000-ft. level. The Victoria company has decided to pay $40,000 cash for the Snowflake group instead of paying for it in stock. It had the option in the matter of payment but decided that the amount called for in stock was too much. The directors of the Emerald have authorized the payment

of the balance due on the one-half interest in the Diamond, Emerald, and Ruby claims. The other half of these claims, which is held by a different party, is under bond and lease to the Emerald.

DENVER, COLORADO

Strike Situation. — Disposal of Coal Lands. — Zinc at Leadville. — Cripple Creek Activities.

The whole State has experienced an unusually prosperous mining season since early in the spring, and with the approach of cold weather the coal mines are adding to the general activity of the industry. The strike in the northern coalfields is, however, still unsettled, and trouble seems imminent, in many places, between the strike-breakers and the union miners. All that is needed is for some over-zealous 'gun man' to start the trouble. On August 30 the operators held a meeting and refused to arbitrate their differences with the 3000 striking miners. A letter was sent to Mr. Brake, State Labor Commissioner, stating that there was nothing to arbitrate. This matter seems to have drifted along now far enough to warrant Mr. Brake in compelling arbitration, according to the power given him by the Seventh General Assembly. This is an admirable chance to try the new legislation which has proved so satisfactory in Canada. Lignite is now selling for $5 per ton in Denver, and if a continued cold spell should occur a coal famine would ensue.

The courts have been busy of late with decisions of interest to the mining fraternity. The now celebrated tax case of the Hart Consolidated Mining Co. et al., against the Teller County officials seems to be settled. The suit was brought to reduce the tax and to prevent the county from disposing of the properties involved at tax sale. Years ago when the case started, the plaintiffs secured a temporary injunction, restraining the county from taxing unproductive mines in the Cripple Creek district, on the same basis as producing mines. The temporary injunction has now been made permanent, and some 26 judgments have been obtained against Teller county in favor of the mining companies involved. The amount to be refunded totals $3666 with court costs added. Another decision of equal interest is that handed down by Judges Vandeventer and Lewis, of the Eighth District United States Circuit Court of Appeals. The suit was one for an injunction against Samuel A. Abbey and John J. Lambert, register and receiver, respectively, of the United States Land Office at Pueblo. The plaintiffs were William G. Pested and Charles Beuchat, both of Trinidad, Colorado, who sought to compel the Government officials to deed 240 acres of coal lands in Las Animas county, Colorado, to them at $20 per acre. The Land Office officials refused to sell the land at that price, demanding from $115 to $135 per acre for it, maintaining that this was a reasonable valuation. The Court held, in brief, that a United States court of equity could not interfere in the disposition of matters that, by law and decisions of courts, were conferred upon the Department of the Interior. It also held that the Department of the Interior was not limited to a certain price in disposing of coal lands, but that a reasonable price could be demanded. The decision infers that $20 was the minimum price, and not the maximum price which the act of 1873 intended the Department to accept.

Exaggerated reports have appeared recently in many newspapers about the discovery of immense bodies of high-grade oxidized zinc ores. It is a noteworthy fact that many of these reports omit the third dimension when describing the size of these and other new finds. It is a fact that large reserves of oxidized zinc ore have been brought to notice either by development or by systematic sampling in old stopes in the Hilltop, Robert E. Lee, Maid of Erin, Henrietta, Wolftone, and a few other mines. The ore has been examined very carefully by representatives of the Empire Zinc Co., who state that by careful sorting and sampling the ore can be brought up to shipping grade, and that a large tonnage is available. It is certainly a pleasure to see a new lease of life granted to such a famous old camp as Leadville, which has seen the placer miner come and go, then its rich lead-silver ores extracted with haste and vigor. The copper boom followed this, and lately the sulphides have gradually decreased in value, until the camp has seemed decadent. This peculiar history of a remarkable camp illustrates, perhaps better than anything else, that we are all apt to find just what we are looking for and nothing else.

Cripple Creek is, as usual, the banner camp of the State with a production of 68,815 tons, of a gross bullion value of $1,412,375. The average value per ton of ore shipped was $20.52. The reduced treatment charges on low-grade ore, put into effect by the American Smelting & Refining Co. on September 26, has been equalled by the Portland Gold Mining Co., and October should see an even larger tonnage of the lower-grade ore. Leasing has also been stimulated by this cut in treatment rates. The Deep Drainage tunnel was advanced 342 ft. in September. There still remains about 700 ft. of driving before the main water course will be cut so that early in December this project should be completed. With the drainage problem settled many of the companies will resume the working of their mines on company account, and it seems to be a very fitting time for them all to adopt the change-room system as has already been done at the Golden Cycle. The gain to the companies and to the miners does not need any further comment, while the elimination of the ore thieves will be a distinct benefit to the whole district.

MEXICO

Cananea Consolidated.— Cinco Minas. — Alvino Mines. — Huasteca Petroleum Company.

L. D. Ricketts, president and general manager of the Cananea Consolidated Copper Co. (Greene Cananea), names ₱6,500,000 as the total of the expenditures to date for improvements made by the present management for decreasing costs and increasing production at Cananea. It will require several months to complete the construction work now under way, and it is expected that the total will be raised to ₱7,500,000. Concerning present production, which is at the rate of 3,500,000 lb. of copper per month, Mr. Ricketts says: "We have found that, owing to the uncertainties of trade, we could not sell copper as fast as we are producing it, and we therefore decided that it was essential to reduce our production in order to avoid the risk of a lower price for copper, or the necessity of storing it in warehouses until such time as it could be sold. We regard as merely temporary the curtailment, and believe that within six months we can increase our production beyond all previous records. The present capacity of our plant is nearly double that of four years ago." The five-year contract recently entered into by the Cananea Consolidated and the Miami Copper Co. for the smelting of Miami concentrate at Cananea calls for the handling of 100 tons per day. It is expected that deliveries will be started January 1. The contract specifies a rate for smelting, and provides that the gold and silver in the Miami product shall be purchased by the Cananea Consolidated. This contract was secured by Mr. Ricketts in competition with American smelters, notably the Copper Queen, of the Phelps-Dodge interests, and it serves to bring prominently to public notice the great economies effected in smelting operations at Cananea by the Ricketts management. It is the first time in the history of mining and smelting on the continent that an arrangement has been made for the shipment of American ores or mill products into Mexico for treatment.

The legal transfer of the Cinco Minas, famous old producers of the Hostotipaquillo district of Jalisco, to the Cinco Minas Co., organized recently by the Marcus Daly interests with a capital of $500,000, has been made. The mines were purchased early last January by H. E. Crawford, representing the Daly interests, for approximately ₱500,000. The new company is a close corporation, all the stock being held by Mrs. Marcus Daly, her son, Marcus Daly II, her son-in-law, J. W. Gerard, judge of the New York Supreme Court, and Mr. Crawford, who is also a relative of the widow of

the Montana millionaire. The mines were under bond to the Daly interests for a year preceding the purchase, and consequently the development for nearly two years has been under the direction of Mr. Crawford. This development has been attended by very gratifying results, and it is now estimated that, inclusive of the large amount of ore left in the workings by the former owners, the proved supplies of profitable ore total about 500,000 tons. Rich ore has been taken out in the course of new development, and present shipments to the smelter average 70 tons per month. This ore has assays from 5 to 10 kg. silver and 50 to 90 gm. gold. The plans of the Cinco Minas Co. call for the erection of a 250-ton plant, and orders for equipment probably will be placed before the end of the year. The process will be direct cyanidation, stamps and tube-mills being installed for crushing and grinding. Arrangements have been made with the Chapala Hydro-Electric & Irrigation Co., now completing a transmission line into the Hostotipaquillo district, for all power needed at a rate of ₱100 per horse-power year. The Marcus Daly interests are heavily interested in the Banco Central, of Mexico City, and in the El Oro Mining & Railway Co., of El Oro. It is now planned to organize a development company to take up and develop Mexican properties.

At a recent general meeting of stockholders of the Avino Mines, Ltd., held in London, a report covering the 14 months since the resumption of work following a reorganization showed a profit at the mines of £4338 6s. 9d. This profit was obtained from the shipment of hand-sorted ores. The company owns a group of famous old producers about ten miles from Gabriel, a station on the Mexican International, and for years attempts have been made to perfect a satisfactory treatment for the lower-grade ore. Concentration and lixiviation processes have been tried. A test plant for a new process of concentration is now in operation at the mines, and a shipment of ore was recently made to England for tests by another process. At the time of the reorganization of the company it was estimated that the proved ore in the mines amounted to 100,000 tons, and while since that time there has been extracted a total of 43,350 tons, the estimate of proved ore is now 107,505 tons. The ore shipped in the last 14 months has averaged 53s. per ton, and the net return to the company has been only 28 shillings.

The Huasteca Petroleum Co., a subsidiary of the Mexican Petroleum Co., has completed an 8-in. pipe-line from its Juan Casiano field, in the Huasteca district of Veracruz, to the gulf port of Tampico. The new line has a capacity of 25,000 bbl. of oil per day. There are five pumping stations, each one of which cost fully $100,000. Each of the five pumps weighs 110 tons. The oil from the Juan Casiano field is delivered to three 55,000-bbl. steel storage tanks on the bank of the Panuco river. The company recently brought in two gushers, and has five other producing wells. E. L. Doheny, of Los Angeles, is at the head of the enterprises. Plans for the piping of oil to the high central tableland, and, at some future date, possibly, to Mexico City, depend on the development of the Juan Casiano field. If great deposits of oil are proved the plans will be carried out, at least to the extent of delivering oil by pipe-line at some point on the tableland from which it can be easily transported by rail to the Mexican capital. The Doheny interests have been engaged for some time in securing right of way for the projected tableland pipe-line. Huasteca oil is exclusively the fuel of the Mexican National Gas Co., another Doheny concern, which has commenced to supply gas in Mexico City. The Mexican Petroleum Co. is supplying 6000 bbl. of fuel oil per day to the National Railways of Mexico, and is producing asphaltum for use in Mexico and for export to other countries. Since 1906 this company has paid nearly $3,000,000 in dividends.

The Dos Estrellas Mining Co., operating the rich Dos Estrellas mine at El Oro, had a production in August of ₱907,825. The expenses amounted to ₱337,221, leaving a profit for the month of ₱570,604. The August profit of the El Oro Mining & Railway Co. was $95,490, and that of the Mexico Mines of El Oro $77,390. The Choix Consolidated Co., a Los Angeles concern, operating in the Choix district of Sinaloa, has placed an order for the erection of a 100-ton smelter at its properties. A 60-ton hot-blast furnace is to be erected at the Carmen mines near Quilá station, in Sinaloa, recently taken over on a royalty basis by Wilkesbarre men. The properties are owned by the Carmen Mining Co., of San Francisco. Foreign mining men of the Zacatecas district are organizing a miners' association, for mutual benefit and the encouragement of mining investments in that portion of Zacatecas. It is hoped to bring about a revival of mining and milling in this district, at one time one of the most productive of Mexico.

BUTTE, MONTANA

Butte & Superior.—Consolidation of Independent Companies Planned.—Anaconda.

The Butte & Superior company management is confident over the outcome of its bond issue, and there is every reason to believe that the company will not only derive sufficient money to carry its operations on an extensive scale, but will be able in the next 30 days to arrange for the construction of a mill on its property to treat the ore. The company has some payments on property due early in the coming year and the bond issue money will also supply enough to meet those obligations. While there are quite a number of small stockholders selling their holdings, the great majority have subscribed for their pro rata allotment and it is stated that W. A. Clark of this city, former United States Senator, will take up the bonds allowed him under his holdings, indeed there is some reason to believe that he will probably take up a quantity of the bonds left over after the stockholders have received their allowance. The time expires October 20 for subscribing to the bonds so far as the stockholders are concerned.

The report that the independent mining companies are to be merged under one management is beginning to receive considerable attention among people interested in mining. Just what will become of the movement it is yet hard to say, but there is no doubt that at least several of the leading men of the independent companies are in favor of the project, provided satisfactory arrangements can be made. At the present time nothing has been done beyond an informal discussion of the subject between some of the heavy stockholders of several companies. Suits are now pending against two of the leading companies, the Tuolumne and Butte-Ballaklava, brought by the Anaconda and North Butte companies claiming the illegal extraction of ore and mining in ground belonging to the latter concerns. It is therefore not at all probable that anything of a decisive character will be done until there is a decision in the cases mentioned which means probably several months. It is said that the proposed alliance or merger was first proposed by F. Augustus Heinze who stands prepared to put the Davis-Daly into the merger, provided suitable terms can be arranged.

A large force of men are at work constructing the new ore-bins for the St. Lawrence mine to take the place of the ones which collapsed a short time ago, while still another force of men is at work re-timbering the shaft of the mine. The latter work would have to be done in a short time even if the accident to the ore bins had not happened, so advantage is being taken of the close down to do the re-timbering now. This month's output will not show any decrease in consequence of the St. Lawrence being down as the output of other mines has been increased to make up for the 1000 tons per day hoisted by the St. Lawrence company. An effort will be made to have the St. Lawrence ready to resume operations about December 1.

The Washoe Sampling Works, belonging to the Anaconda company which were destroyed by fire a few months ago, are to be rebuilt at once. Since the destruction of the works all the custom ores have been sent direct to Anaconda where they have been treated at the sampler connected with the smelter, but this has been found very inconvenient to the prospectors and small mining people, and the Anaconda company therefore decided to replace the works. The new works will have a capacity of about 1500 tons per day and

will be constructed of reinforced concrete with monolithic concrete and steel beams. The new buildings will cost in the vicinity of $100,000. Work has been commenced on the foundation and it is expected to have the works ready for operation by March 1. The leading attorneys for the Anaconda Copper Mining Co. have gone to San Francisco to appear before the United States Court of Appeals in the smoke case. This was heard before the United States court of this district more than one year ago and Judge W. H. Hunt, after reviewing evidence which had been taken before the master in chancery, refused to grant the demand of the Deer Lodge ranchers that an order issue closing the Washoe smelter, but did say that there had been a small damage to vegetation which he asked the company to so remedy as to prevent the alleged poisonous gases from floating through the air and down into the Deer Lodge valley. The ranchers were not satisfied with the decision and took an appeal.

NEW YORK

Granby Report. — Copper Situation. — Oil. — Railroad Building. — Nevada Mines.

The long-talked of meeting of the Granby Mining, Smelting & Power Co. was held this week and was replete with sensation. Resignations were in order all along the line and included Jacob Langeloth, the president, who is the largest individual holder in the company, Henry Lee Higginson, George Crawford Clark, George Crawford Clark, Jr., and Payne Whitney. George M. Luther of the Nichols Copper Co., refiners at Laurel Hill, Long Island, was elected president to fill Mr. Langeloth's place. There was some heated discussion concerning the leakage of the facts in Otto Sussmann's report, and after a statement by Mr. Langeloth that neither officials nor directors had any knowledge of the report until after it was printed, a resolution was introduced asking for an investigation of the matter. After some discussion of the situation and of the apparent fact that the Granby was attacked by someone entirely outside of the company the resolution was tabled. That part of Mr. Sussmann's report which tumbled the Granby market about the ears of the unsuspecting shareholders is as follows. "You are, in my opinion, at present confronted with a situation where you have an up-to-date smelter, with a capacity of 4000 tons per day, and a mine the life of which appears to be limited to a few years. Therefore, further steps should be taken toward securing a further alimentation of your smelter from other sources. Your mine management has lately taken an option on some ground north of your own properties, and this is now being explored with drills. Exploration work of outside properties should be pushed vigorously, and at the same time part of the smelting capacity should be used for customs ore." In answer to direct inquiry, Jay P. Graves, general manager, stated that, while drilling operations had been carried on with satisfactory results, such work had not yet reached a point where it is possible to estimate developed tonnage, nor would Mr. Graves attempt to estimate the probable life of the Granby. Part of the smelting capacity is employed on custom work and an effort is to be made to secure additional smelting contracts. The balance sheet shows a deficit of $234,317 for the year; a surplus of $2,464,370; the actual cash and copper on hand is given at $1,012,000. At the British Columbia, the situation is much improved; the Rawhide mine of the New Dominion is in operation, the product being sent to the Greenwood smelter of the British Columbia. The second furnace at the Greenwood smelter has been enlarged and was blown in this week. The entire plant can now handle 2700 tons of ore per day.

The copper situation is looked upon much more hopefully than for some months. The decrease in the visible supply for the month of September is estimated at 7,168,000 lb. The foreign visible supply is now estimated at 211,276,860 lb., which compares with 255,584,000 on February 15 last when the accumulated surplus reached its high mark. Since that date there has been an uninterrupted shrinkage amounting now to 45,184,040 lb.

The situation in oil is attracting almost as much attention as the now rapidly clearing copper situation did a few months ago. The Shell company, of which Sir Marcus Samuel, of London, is the head, has started a war on the Standard Oil Co. for the European trade. Competition has become so strong that the Shell company is selling its products in the United States, all trade agreements have been declared off and it is said record low figures are likely to be made for all petroleum products. The conditions in oil greatly resemble those governing the copper trade. Consumption is increasing, but production is gaining even faster, and the only saving of the situation lies in sane curtailment and conservation. The Standard's side of the fight for control of the markets of the world is embodied in a recent statement which claims that the lower prices just made are for the purpose of educating people in the uses of refined oil. The Standard says in part: "During the last three years, the world's production of crude oil has been increasing at a rate far in excess of the increase in the world's consumption of kerosene or refined oil. In 1906 the world's production of crude petroleum was 213,000,000 bbl. In 1909 the production was 304,000,000 bbl., an increase of 91,000,000. The increase in the crude oil production in the United States during the same period was 60,000,000 or two-thirds of the entire world's increase. The world's refined oil (kerosene) business in 1906 was 48,000,000 bbl., and in 1909 was 53,000,000, an increase of 5,000,000. These figures show an increase in crude-oil production from 1906 to 1909 of 42½% while consumption of refined oil has increased but 10⅘%. While it is true that during the past three years a very large market in the United States has been created for oil as fuel, still stocks are increasing rapidly and at the present time in the United States alone there is held in tankage by the Standard Oil Co. and others a stock of over 115,000,000 barrels."

Montgomery-Shoshone Mine and Mill.

The various railway projects now being carried on by American financiers in foreign countries are growing in importance. The development of the valley of the Euphrates under a concession granted by the Turkish government, is one which recently attracted some attention. Now a group of New York capitalists is undertaking the construction of the Pan-American Transcontinental railway, which is to reach from Colonia northward across Uruguay to San Luiz in the Brazilian State of Rio Grande de Sul, a distance of 420 miles. The people behind the enterprise are the managers and officials of the Isaac G. Johnson Steel Co. of New York. It is stated that about 145 miles of the Cop-

per River railroad in Alaska has been completed, the line extending from Cordova to the Kuskulana river, which is about 50 miles from the Bonanza mines. A tram line has been built from the Bonanza mines to the railroad terminus, the concentrator is nearly completed and will be ready for production by spring. It is claimed that there is about 100,000 tons of copper ore blocked out.

The special meeting of the stockholders of the Montgomery Shoshone Consolidated Mining Co. was held this week and the detailed report presented by the general manager considered. The real question in issue was the continuance of operations and upon the manager's statement that ore supplies are sufficient for about three months' operations, it was decided to continue work until the present ore reserves are exhausted and then close down the property. It is stated that during the past three months there have been several hundred names added to the stockholders' list of the Nevada Consolidated, shareholders now numbering something more than 6000 and being a greater number than in any mining company in the United States, with the exception of the Amalgamated Copper Company.

LONDON

Don Proprietary Mines.—Tin Mining.—Cam & Motor Gold Mining Co. —Amalgamated Secures Option on Ferrobamba Property.

The Don Proprietary Mines has been successfully floated in London without the issue of a prospectus, for the purpose of acquiring the Don, Peggy, and Scouts mines in Rhodesia. The company is registered under local laws and has an office in London. Clement Dixon is consulting engineer, and Thomas J. Gibb is on the London board. The Don mine is eight miles south of Selukwe, Scouts is at Gwelo, and Peggy is farther to the southwest near the Claremont and Nelly mines. At the Don mine, the vein has been traced for 1000 ft. on the surface and a shaft has proved the vein to average 32 dwt. over 22 in. Stoping operations are done at a width of 36 in., and the average content of the ore mined is thus reduced to 19 dwt. A 10-stamp mill and cyanide plant were erected at the beginning of the year and crushing started in May. During July 1200 tons was treated, and the recovery was worth £2600 or 43s. 4d. per ton. The cost of mining and milling was approximately £1000 or 16s. 8d. per ton leaving a profit of 26s. 8d. per ton. Mr. Dixon advises that work should be centred on further development and that in the meantime the mill should run only half time. Less development has been done at the Peggy mine, but the indications are highly favorable and a battery consisting of 7 stamps together with cyanide plant has been erected. The 'probable' ore here is 8500 tons averaging 12½ dwt. over 31 in. The Scouts property has not been fully proved but surface indications are excellent and warrant vigorous development. The nominal capital of the company is £75,000, and of this £20,000 is represented by cash available as working capital; as two of the mines are equipped with reduction and extraction plant the prospects of the company appear to be favorable and promising.

The Tinfields of Northern Nigeria is the name of a company formed by the Champion Gold Reefs of West Africa for the purpose of acquiring two tin-gravel properties in northern Nigeria. One of these is the Federri and is eight miles in extent; 300 acres has been proved to contain a gravel deposit from 2½ to 3½ yd. deep and averaging from 3 to 6 lb. of cassiterite per cubic yard. It is intended to erect a plant to produce 300 tons of cassiterite per year and the cost is estimated at £42 per ton. The second property is the Dila river or Doss, which consists of nine miles of country with a proved area of 400 acres, 3 to 5 yd. deep and averaging 3 lb. per cu. yd. The output is calculated at 500 tons per year at a cost of £40 per ton. L. H. L. Huddart is consulting engineer and C. G. Lush is on the board. The capital of the company is £100,000 of which £70,000 in shares goes as purchase price and £25,000 has been subscribed as working capital. At the above mentioned rate of working the proved areas are expected to last 26 and 23 years respectively.

The Anchor Tin Mining company was formed in London in Mexico

1895 to acquire a property at Lottah in the northeast of Tasmania. The property is a stockwork in granite and the tin content is very small. The efficiency of operation is high but the profit has never been great enough to provide a dividend. The company was reconstructed in 1902 and 1909. Bedford McNeill is consulting engineer and James B. Lewis is manager. At the reconstruction in February, 1909, the issued capital was reduced to £25,159 in ordinary shares and £6540 in preference shares, and there are £52,000 of 4% debentures. During the last 18 months the work at the mine and mill has been suspended twice on account of drought, which Mr. Lewis says has been the most severe in his experience. Consequently the output has been smaller and the cost higher than usual. The ore treated in the 100-stamp mill during the 14 months ended March 31 was 102,283 tons, not much more than half the usual amount, and the average number of stamps running was 66. The black-tin concentrate recovered was 158 tons. This is 3½ lb. of black tin or 2½ lb. metallic tin per ton. The concentrate is smelted at Mount Bischoff and the revenue from the sale during the year was £15,743, less £578 smelting charges. The total cost in Tasmania and London was £17,854 and after adjusting accounts for stocks of tin in hand at the beginning and end of the period, the loss was £1866. Another unfavorable event was a bush fire which destroyed some of the woodwork at the mine and mill. Seeing that the circumstances connected with the drought have been so much against the success of operations the debenture holders have agreed to wait for their interest and the directors for their fees. An agreement has been made with the Tasmanian Government whereby £5000 has been borrowed from public funds for five years for the erection of an aerial cable-way. This is now being constructed. Additional leases have been acquired.

The Cam & Motor Gold Mining Co. has been formed by the London & Rhoedsian Mining & Land Co., which is controlled by Julius Weil & Co., for the purpose of acquiring the Cam & Motor gold mines and other claims in the Gatooma district of southern Rhodesia. Other companies beside that mentioned above have interests in the properties. The capital of the company is £500,000 of which £225,000 in shares and £100,000 in cash goes to the vendors: 225,000 shares are being offered to the public at 27s. 6d. each, the whole issue being underwritten by J. G. Bone & Sons, who have a call on the remaining 50,000 shares. The company therefore starts out with approximately £200,000 in cash for working capital. The Cam & Motor mines have been examined by V. S. Allen, of the firm of Pearse, Kingston & Browne. The geological formation consists of crystalline schists traversed by dikes of varying character. The ore is found in connection with silicious impregnations of the rocks and dikes, and arsenic and antimony are found associated with it. The main lode at the Motor has been proved by two levels, No. 1 being in ore for 685 ft., and No. 2, 280 ft., the average width of the lode being from 4 to 6 ft. and the content 7 dwt. On the main lode at the Cam four levels have been started, and the width is 5 to 6 ft. averaging 14 dwt. At both mines additional lenses and shoots of ore are found, and the orebodies generally are difficult to estimate for both width and content. Mr. Allen figures that 222,000 tons are exposed in the Motor averaging 10½ dwt., and 80,000 tons in the Cam averaging 11½ dwt. He recommends development on a large scale and the provision of extensive plant, mentioning £150,000 as a suitable sum for the purpose.

A. C. Burrage on behalf of the Amalgamated Copper Co., has acquired an option on the property of the Ferrobamba Copper Co. in Peru. Mr. Burrage has purchased outright the remaining unissued shares of Ferrobamba Limited, 3500 in number, at the price of £3 each. He is sending his own representatives to make an examination and he has an option until May 1 of next year to acquire the property for £250,000 in cash and £420,000 in shares in an American company that will have a nominal capital of £1,400,000. The balance of £730,000 will be subscribed by Mr. Burrage and his friends at par to provide working capital. The cash purchase consideration will be paid in yearly installments.

General Mining News

ALASKA

(Special Correspondence).—The Mt. Andrew, Jumbo, and It mines are the three steady producers in this district. That the ore has increased in value with depth seems to be the general report from these properties.——A 500-ft. shaft is being sunk on the Red Wing. This property has produced some high-grade copper and gold ore and will probably be counted among the producers next year.——Development is going on steadily at the Gold Stream with encouraging results. A. A. Wakefield is in charge. The ore is gold, silver, and lead.——The Dall Island Marble Co. is sending a crew of 10 men to commence prospect work on a large deposit of marble on Dall Island. Surface indications are favorable and samples from this property have been examined by experts and pronounced first-class.——A party of 10 men, headed by J. J. Martin of the Chicago Exploration Co., just arrived here from the Unuk river, having made a preliminary examination of the placer ground in the valley. This work will be continued next season and if the results are satisfactory dredges will be installed.

Ketchikan, October 1.

The official report of the Alaska Gold Mining Co. for the month ended August 15, is as follows: Mill time elapsed 31 days; Ready Bullion mill (120 stamps) ran 30 days, 15 hr., 55 min.; water-power 21 days, 23 hr., 39 min.; steam-power, 8 days, 15 hr., 56 min; 700 mill (100 stamps) ran 30 days, 18 hr., 30 min.; water-power 27 days, 1 hr., 30 min.; steam-power 3 days, 17 hr.; ore crushed: Ready Bullion mill 21,140 tons; 700 mill: 16,926 tons; sulphides saved: Ready Bullion mill 375 tons; 700 mill: 280 tons.

	R. B. mill.	700 mill.
Estimated value of free gold	$25,134.69	$23,533.00
Estimated value concentrate	17,450.77	14,588.90
Estimated realizable value	40,087.12	36,206.57
Operating expense	26,023.83	23,097.54
	$14,060.29	$13,109.03
Construction expense	10,961.37	5,326.22
Yield per ton of ore milled	2.01	2.25

Development Ready Bullion claim, 324 ft. in vein on 1650-ft. level; assay value, $2.46; on 1800-ft. level, 188 ft. in ore, value $1.08; in waste, 75 ft.; on 700-ft. claim, on 770-ft. level, 82 ft. in vein; assay value, $1.54; on 1100-ft. level, 44 ft. in vein, assay value $2.90; on 1210-ft. level, 73 ft. in vein, assay value, $2.27; stock of broken ore, Ready Bullion, 8157 tons in 700-ft. claim, 4411 tons.

ARIZONA

COCHISE COUNTY

The Commonwealth Mining & Milling Co. operating near Pearce has completed the new cyanide plant and is treating 125 tons of ore per day. A short time ago the company erected a plant to treat a large pile of tailing that had accumulated from the operation of the mill. A few days after the mill was finished it was destroyed by fire and the present plant has been installed to replace it.——A recent sample taken across the vein at the Gold Queen property assayed $77 per ton.

GILA COUNTY

(Special Correspondence).—The diamond-drill on the 660-ft. level of the Superior & Globe property is 300 ft. below that level and in much better ground for drilling. At or about the 270-ft. mark soft ground was cut which caused much trouble by running and filling the hole. This had to be cemented and re-drilled, which consumed a good deal of time during the month of September. The depth now attained is one-half of that which the hole will ultimately reach.——The development at the Arizona Michigan property for the month of September amounted to 226 ft. Since that time the Black Bird shaft and its two cross-cuts on the 400-ft. level have been discontinued and development concentrated in the Telfair shaft workings.

Miami, October 8.

MARICOPA COUNTY

The Arizona di Borgia group of claims in the Vulture district has been bonded and work will be resumed at once in their development. The 50-ft. shaft will be cleaned out and the drifts sampled before any attempt is made to plan new workings.——The clean-up at the old mill on the Vulture mine for September amounted to $6800. The new mill is now handling 100 tons of ore per day.

MOHAVE COUNTY

A body of ore has been opened on the 300-ft. level of the Siamese mine of the Arizona Southwestern Copper Co.——Another carload of mining machinery has arrived in Kingman and is being forwarded to the property of the Frisco Power & Mining Co., where a 100-ton plant is in course of erection.——The new shaft at the IXL mine is going down rapidly having attained a depth of over 100 ft. It is the intention of the management to continue sinking till the shaft is 100 ft. below the old workings from which a large tonnage of high-grade ore has been stoped.

YUMA COUNTY

The shoot on the 200-ft. level of the Paycar group near Bouse has been opened over 50 ft. showing a width from 18 to 24 in. and assays of over $200 per ton in gold have been obtained.——After a temporary shut-down the smelter of the Clara Consolidated has again been blown in.——Operations have been resumed at the property of the Consolidation Copper Company.

CALIFORNIA

NEVADA COUNTY

At a recent meeting of the board of directors of the Prudential Mining Co. an assessment was levied to raise money to continue unwatering the property. There is still 265 ft. of water in the shaft. It is stated that the present assessment will raise sufficient funds to completely drain the mine and continue the development.——Work has been stopped at the Blue Lead gravel mine near Relief till the winter rains insure an ample supply of water to wash the gravel which is reported to be worth $3 to $4 per car. An 800-ft. adit has been driven through the bedrock and a raise driven to the channel.

SIERRA COUNTY

The people who held the bond on the Sixteen-to-One mine at Alleghany have not made the last payment on the bond and the property has reverted to the original owners who will continue with the development of the mine.——The electric system at the Alaska mine has been completed and the operators will not have to depend on water in the future for their power. The shaft is to be sunk to the 700-ft. level which is 250 ft. below the old workings and drifts driven on the ore from that point.

TUOLUMNE COUNTY

(Special Correspondence).—A discovery of great importance was made at the App property, now owned by the Nevills Investment Co., a few days ago, when two prospectors casually entered the old shaft on the Heslep claim and found uncovered on the 200-ft. level what is thought to be the rich shoot lost many years ago by a French company which at that time was operating the property. It is said samples from across the vein assayed from $13 to $125 per ton. The company, it is understood, will cross-cut from the App shaft to tap the rich body of ore at a depth of about 300 ft. The Heslep claim adjoins the App on the east.——The Gold Ship Mining Co. has at last been granted permission to erect an electric pole-line across a certain part of the Forest Reserve and commenced the long-delayed work a few days ago. The power will be purchased from the Tuolumne Electric Co., whose transmission line passes within two miles of the Gold Ship's property.——Considerable development is to be done at the Spring Gulch group, recently bonded to W. B. McCubbin and George Ash.——The completion of the improvements begun at the Mazeppa mine is being retarded as a result of the Jumper people objecting to the laying of a pipe-line across their land. Among other improvements under way or about to

be commenced is the addition of 10 stamps to the mill.——A 10-in. vein of unusually rich ore has been uncovered in the Experience mine, in the Big Oak Flat district, by William Pool and Frank DeFerrari.——Articles of incorporation of the Columbia Marble Co. have just been filed in this county. The capital stock is $750,000 and the directors are David Hearfield, Edgar T. Zook, and James H. Follis of Marin county, W. T. Barnett of Alameda county, and R. H. Van Norden of San Francisco.——The work of unwatering the Black Oak shaft has not progressed quite satisfactorily, repeated delays having been caused by the breaking of machinery. Nevertheless it is expected that sinking an additional 100 ft. will be commenced soon.

Tuolumne, October 9.

COLORADO

BOULDER COUNTY

A movement is on foot among the mining men of this county to establish a modern cyanide plant at some central point that will treat custom ores. The Boulder County Mining Association co-operating with the Commercial Association is endeavoring to finance the undertaking. It is believed that such a plant would greatly stimulate the production of the county as it would give the owners of small properties a better outlet for their ore.——The Frigid Mining Co. is shipping two carloads of tungsten ore per week to the Eureka mill at Boulder. Arrangements are under way for the installation of a compressor and air-drills.

CLEAR CREEK COUNTY

(Special Correspondence).—Lawson & Co., operating through the Princess of India adit under lease, are shipping a heavy tonnage of ore that is worth $60 per ton silver and lead.——The Key West mine on Leavenworth mountain will shortly be entered among the list of shippers. A streak of ore 8 in. wide is showing in the west drift that is worth $55 per ton gold and silver. E. J. Butts is manager.——The Sprankle property on Covode mountain, has been taken under bond and lease by Frank Straub of Denver. A campaign of development will at once be put under way.——It is reported that work will be resumed during the next few days upon the Bellevue-Hudson mine on Columbia mountain. O. H. Mann, manager for the Southwestern Mines Co., arrived from Boston this week and states that the financial difficulties have been adjudicated.

Georgetown, October 8.

GILPIN COUNTY

(Special Correspondence).—The Pine Comb adit is being driven steadily forward. A vein was recently intersected and a streak of ore 10 in. wide uncovered that is worth $30 per ton gold and silver. E. Shous is manager.——The water is being lifted from the Hubert mine in Nevadaville, and work will soon be put under way sinking the shaft, the object being to connect with the Newhouse adit-level. H. C. Bolsinger is manager.——Work is to be resumed on the Ralls county mine. The shaft will have to be re-timbered from the 500 to the 700-ft. level. It is proposed to sink to a depth of 1000 ft.——Work was put under way last week at the Federal mine. R. Hughes is manager.——Heavy shipments are being made from the Old Town mine by Pike & Co., who are operating under lease. The ore is worth $70 per ton.

Central City, October 10.

LAS ANIMAS COUNTY

An explosion in the mine of the Colorado Iron & Fuel Co. at Starkville entombed 52 men. The property has been classed as a non-gaseous mine and no safety lamps were used, though firing off the solid was not allowed on account of the liability of dust explosions. Connections have been made with the underground workings of the adjoining property and it is probable that a number of the men will be rescued.

SAN JUAN COUNTY

The Bagley adit was the scene of an excellent discovery a few days ago when a large vein of galena ore of milling grade was opened at considerable depth on the Sewall lode. The vein varies from one to four feet in width on the surface from which a number of good assays were obtained before starting the adit that would intersect the lode.

SAN MIGUEL COUNTY

The new mill at the Lewis mine has been started and the machinery adjusted. The Lewis mine is one of the old producers of the county being a heavy shipper for a long time, and it is thought that the construction of the new plant will greatly reduce this expense thereby adding to the company's profits.——The La Junta company has completed a new tram from the Orion mine to the mill.

SUMMIT COUNTY

The Sliver King mill in the Montezuma district is again in operation after being thoroughly overhauled and equipped with additional machinery. The stamps are dropping on ore from the Silver Cave, Silver King, and Silver Princess mines, situated on Glacier mountain. Tramways have been built connecting the mill and mines which are old produc-

Map of Cripple Creek District.

ers credited with a heavy production of lead-silver ore.——The Snider Consolidated Mines Co., which is operating the Lightning group on Mineral hill and the St. John group on Mt. Baldy, has opened a quartz vein on the latter group that is over 19 ft. wide and which contains free gold.

TELLER COUNTY

An option has been obtained on one of the local mills in the Cripple Creek district and a canvass is being made of the independent shippers to ascertain if a sufficient supply of ore can be obtained to warrant the establishment of a custom plant.——Shipping ore has been found on the 800-ft. level of the Hoosier mine on Tenderfoot hill which is operated by the Cosmopolitan Mining & Leasing Co., and a consignment will soon be forwarded to one of the local mills.——Millar & Carnduff are sacking ore from their lease in the Conundrum mine on Gold hill. Assays as high as $300 gold per ton have been obtained.

IDAHO

SHOSHONE COUNTY

M. W. Bacon of Butte bought control of the Independence Lead Mines, Ltd., for $5000 at a sheriff's sale in Spokane on October 1. The sale was of 850,000 shares of the stock of the Independence company, which is capitalized at 1,250,000 shares, and was made in pursuance of a judgment for $55,000 obtained by F. Augustus Heinze against Kennedy J. Hanley of Spokane. The Independence company owns a group of partly developed claims between the Morning and

Hunter mines at Mullan. It was expected that Mr. Hanley or his friends would appear at the sale and bid the stock up to a price which would at least satisfy the judgment.——A 47-ft. vein of concentrating ore has been exposed in the workings of the Carney Copper Mining Co.'s property, situated in the Mullan district. J. L. Martin of Spokane, president and general manager, says the assays vary from 5 to 35% copper. Since this exposure the drift has been extended 100 ft. in concentrating ore with a 2-ft. streak of shipping grade. This is at a vertical depth of 170 ft.——F. C. Bailey has brought several samples of native silver to Spokane from the Roanoke property, a mile east of the Bunker Hill & Sullivan mine. The ore was taken from the shaft at a depth of 20 ft., and contains lead in addition to the silver.

MICHIGAN

The Ojibway Mining Co. is steadily increasing its underground openings in both shafts, and in this work is developing some excellent copper measures. The better showings by far are those obtaining in the north end openings in the No. 1 shaft, where practically all drifts are in mineralized ground. The laterals in the No. 2 shaft are not so encouraging and are for the greater part in a badly shattered formation. The No. 1 shaft is down around 1330 ft. and the No. 2 is sinking below the 1550-ft. mark. The shafts are connected at the 800-ft. level.——Shaft sinking on the property of the Houghton Copper Co. has again been resumed after several weeks' idleness during which time the collar of the shaft was lined with concrete. The shaft is down about 60 ft. in the barren trap rock contact. Crosscutting will be necessary to connect with the copper-bearing ground, and the first of these will probably be run at a depth of 150 ft. from surface. Several of the mine buildings are already up and preparations are under way to enclose the shaft collar. All this work is of a permanent character, the results obtained in diamond-drilling this part of the Baltic-Superior lode and the excellent showings of copper ground maintained in the Superior mine adjoining indicating a rich though rather small mine will be opened on this property.

NEVADA

CLARK COUNTY

Edwin Carleson ran a 30-ton lot of ore from his lease on the Good Hope through the Cyrus Noble mill in the Searchlight district obtaining a $700 bar. This is the fourth shipment of high-grade ore made from these workings. The shaft has been sunk 70 ft. with a whim on an ore that averages $30 per ton.——A 40-ton lot of $30 ore has been hauled from the Perkins-Kirkeby-Gains lease to the Knight mill. The lessees are stoping from the east on the 100-ft. level about 100 ft. from the shaft.——Knight, Hammil & Colton, who have a lease on the I.X.L. property have opened a new shoot by raising from the old Spink adit. The ore is four feet wide and a shipment will be hauled to the mill within a few days.

ESMERALDA COUNTY

The new 3-compartment shaft on the Florence property at Goldfield has been completed from the 530-ft. level and as soon as the air-pipe can be installed additional drills will be started underground. Two 3-ton skips will be installed and sinking continued to the 750-ft. level.——Combination Fraction is stoping 50 tons of ore per day.——The Consolidated is handling 900 tons of ore per day. The orebody on the 1000-ft. level of the Clermont has been opened about 100 ft., the shoot showing a width of 3 to 15 ft. with an average value of $65 per ton.

HUMBOLDT COUNTY

(Special Correspondence).—The National Mining Co. of Nevada, operating the National mines at National, recently shipped 14 bars of bullion to San Francisco. It is estimated that the approximate value was $95,000. The company also sent out a shipment of tailing, valued at about $45,000, to the smelters. Most of the rich ore came from the old Stall workings, and it was found impossible to save all the gold in the mill, a considerable amount remaining in the tailing. This was dried and shipped to smelters.——The R. M. Edmunds lease on Mayflower has opened four inches of bonanza ore. The discovery was made in a 65-ft. winze, sunk from the end of a 500-ft. adit. The vein appears to be an entirely new orebody.——The Earl Hyde lease on the north end of the National on Charleston hill has opened a streak of rich ore. This extends the proved ore belt over 1000 ft. to the north.——An important discovery of stephanite is reported from the Anderson group on Threemile creek, south of Radiator hill.

Winnemucca, October 7.

NYE COUNTY

(Special Correspondence).—While driving a drift through the big vein on the 800-ft. level of MacNamara, 12 in. of ore, said to assay $80 per ton, was opened.——The West End Mining Co. is arranging for the installation of a more powerful hoisting plant and will send the shaft deeper. Stoping is under way above the 250 and 400-ft. levels.——The shaft at the Mizpah Extension has attained a depth of 950 ft. and is still in rhyolite. As soon as the 1000-ft. point has been reached lateral work will be commenced.——The new camp of Cedar Corrals, about twenty miles east of Tonopah is attracting some attention, following reports of the discovery of gold-bearing quartz in rhyolite. Several parties of prospectors have gone to the new district from this camp.——The new mill of the Tonopah-Liberty Mining Co. at Liberty, near Tonopah, has been completed, and started in full operation on October 2. The plant is operated throughout by electricity, supplied from the main line of the Nevada-California Power Co., and consists of a Blake crusher, Ingersoll-Rand air-compressor, Lidgerwood hoist, Chilean mill, tube-mill, Oliver filter, Westinghouse electrical equipment, and Trent mechanical agitators, together with the most modern arrangement of tanks, making a complete all-sliming cyanide plant, with a capacity of 125 tons of ore per day. The company owns 15 full mining claims, with abundant water supply, and has about two miles of underground workings. The stock is held principally by Philadelphians. James G. Lindsay is president of the company. The Traylor Engineering Co. of Allentown designed and built the plant.

STOREY COUNTY

In the C. & C. shaft the pumps have lowered the water 300 ft. below the 2350-ft. and much of the debris has been removed below the 2450-ft. point.——In the Ward shaft the 2475-ft. pump station has been advanced its full width for 100 ft. and all the sills for the station are in place. On the 2100-ft. station the concrete floor to the tank station has been completed and the suction pipes from the pumps to the tank laid.

WHITE PINE COUNTY

The report of E. E. Chase on the Nevada United mines at Ward has been given to the Eastern interests represented by Mr. Chase, and it is reported that attention is again being given to the project of constructing a railroad from Ely to that town. Development has been carried on at these properties for about four years and there is a large tonnage blocked out that will assay between 10 and 15% lead with occasional shoots which contain considerable silver.——The capitalization of the Ely Central Copper Mining Co. has been increased from 1,200,000 shares par value $100 to 1,600,000 shares of the same value.——The Cole-Ryan interests have purchased the Ely holdings of the Gunn-Thompson people and it is reported are figuring on erecting a smelter in the Ely district. The properties include a number of valuable claims, townsite, smelter site, and extensive water rights.——A. G. Burritt, manager of the Amalgamated Nevada Mines Co., has purchased the Blackhorse mines in the eastern part of the county for $50,000. A cash payment of $12,000 was made, the balance to be paid by the end of the year.——The Ohuana Mining Co., operating in the Sacramento Pass district, has placed orders for a mill that will treat 30 tons of ore per day. The machinery is to be delivered within the next month.

UTAH

BEAVER COUNTY

(Special Correspondence).—The Star district, situated eleven or twelve miles southwest from Milford, has been brought to favorable notice by the development of such properties as the Red Warrior, Burning Moscow, Commonwealth, and that of the Utah Mining, Milling & Transportation Co. In general, the country rock is limestone, the ore occurring in fissures and bedded veins. The Red Warrior was partly developed a good many years ago, but the Red Warrior Mining Co., composed mostly of Duluth operators, came into possession of it in February, 1908; and since that date 96 cars of ore, aggregating 4800 tons, sampling 28% lead, 28% iron, and 14 oz. silver per ton, have been shipped to the smelters. The lead is in carbonate form and the iron is oxidized, the only exception being the occurrence of small isolated bodies of galena. The property is opened by a 500-ft. vertical shaft with levels from the 100, 200, 300, and 500-ft. stations. An 87-ft. cross-cut leads to the ore body from the 100-ft. station; the vein is cut by the shaft at the 200, and is opened by a 130-ft. cross-cut from the 300-ft. station. The deepest level is one of 346 ft. driven from the 500-ft. station, the work in the face of this indicating close proximity to the vein. This work, supplemented by a large amount of driving in ore on the different levels, serves to define the vein as one having a north-south strike, an east dip of 45°, and that within the vein is an ore-shoot which has a continuity of 1100 ft. on a pitch of 30°. While this is not a contact vein, it has some of the characteristics of a contact because the limestone walls are dissimilar. An important part of the development consists of a 150-ft. winze on a 45° incline from the 300-ft. level. A skip is operated on this incline by an air-hoist. Off this winze is a sub-level on the vein and from it a second winze is being sunk. It is proposed to make a raise from the 500-ft. level to a connection with the incline winze from the 300-ft. level to develop ore and establish ventilation. The power for hoisting and driving the air-compressor is supplied by gasoline engines. W. J. Merritt, the superintendent, has been in that position for the last year. He likewise has charge of the development of the Mowitza, an adjoining property, controlled by the same interests that own the Red Warrior. The former has a 670-ft. shaft and some lateral work, but not a great amount of ore.——The Burning Moscow is a well-developed ore-producing mine, situated on the opposite side of a mountain from the Red Warrior, and is considered on the same mineral zone. Mathew Cullen, of Salt Lake, has a controlling interest, and Joseph L. Rawlins is the company's manager. The mine is developed and operated from a 500-ft. vertical shaft, the principal working levels being at 300, 400, 450, and 500 ft. Two winzes are being sunk from the 400-ft. level. The ore consists of lead carbonate and chloride of silver, with a considerable amount of copper carbonate. The work is under direction of Josiah Osborne, who states that 2200 tons of ore has been shipped from the mine since September, 1909.

Milford, October 8.

SUMMIT COUNTY

(Special Correspondence).—The Little Bell Consolidated Mining Co., whose property is situated a short distance south from the Daly-West mine, is shipping 150 tons per month of first-grade ore to the smelters, and is paying dividends. Solon Spiro is general manager, E. L. Talbot is superintendent. A concentrating mill, treating 100 tons per day, will be in operation by October 15. The machinery will be operated by electric power, transmitted from the plant of Knight & Co. on Snake creek. The ore, which is hoisted by steam power from the 800-ft. shaft, consists of lead carbonate, galena, and silver, accompanied by some copper and gold, all in a quartz and limestone gangue. The mill will start on a second-grade dump which probably contains 15,000 to 20,000 tons. The ore first will be reduced to 1-in. size by a 9 by 15-in. Blake crusher, passing thence through a trommel having ¼-in. screens. The sampling will be done by a Cole automatic sampler. The trommel oversize goes to a set of rolls that crush to ¼-in. size. This roll product and the trommel undersize are then elevated to 8 and 12-mesh trommels; the oversize from these passes to two latest pattern Richards' pulsator jigs, the tailing from the latter is ground to 12-mesh by an Allis-Chalmers Chilean mill. The product of the latter and the undersize from the 12-mesh trommel are elevated to a 20-mesh Callow traveling screen; the oversize from the latter is returned to the Chilean mill, and the undersize to a 40-mesh Callow screen. The oversize from the last screen passes to an 8-ft. Callow settling tank, in which the pulp is thickened and concentrated over a Wilfley table; the undersize from the same screen goes to a 5-spigot Janney mechanical classifier. The material from the first two spigots flows to two 8-ft. Callow tanks, and is then concentrated by a Wilfley table. Material from the other three spigots, consisting of the finer sand, goes to three Callow settling tanks, the heavy material passing to three Card tables. The overflow from the Janney classifiers is thickened in a Callow tank and concentrated over a 6-ft. Frue vanner. The middling from all the tables is elevated to the Chilean mill for re-grinding. The concentrate product is to be laundered into an 80-ton, 2-compartment bin, in which it is dewatered before being hauled to the railroad. Rush T. Sill, who has charge of the mill, estimates that the ratio of concentration will be about 6 into 1.

Park City, October 8.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—Sixty per cent of the purchase price has now been paid upon the large group of mineral properties and smelter at Nelson, recently consolidated and bought by the associates of R. S. Lennie. It is the desire of the capitalists interested to own the property outright and the remaining 40% will be paid within the next six months. Work will be commenced as soon as the engineers have finished their examination of the property and it is known where this can be most expeditiously carried on. A large working force will be employed when the enterprise gets under full sway and the Nelson smelter will be refitted and blown in.——The mineral display at the Nelson fair this year was the best that has ever been seen there. The Nicola, Rossland, Portland Canal, McGillivray, Sandon, Lardeau, Poplar Creek, Ainsworth, Sheep Creek, Ymir, Bayonne, Nelson, and other mining districts were fitly represented. The Nicola Valley exhibit took first prize. The display comprised copper ore, native copper, gold-copper, bornite, chalcocite, hematite, semi-bituminous coal, fossil coal, galena, and gypsum. The Rossland display was a close second, showing representative gold-copper, gold ore, gold-copper-silver, sulphide of silver and copper, gold, galena, and zinc ore. The exhibit of gold-bearing ores from Nelson district was highly commended, as was the silver-lead display from the Slocan-Ainsworth district. ——The air-compressor for the Yankee Girl Gold Mines, Ltd., has now been delivered and the work of getting it in position will be hurried through as rapidly as possible. This machine will have a capacity of over 550 cu. ft. per min. ——The second payment has been made on the Clyde-Belt bond, Sheep creek. A new 400-ft. adit is being driven to intersect the main vein. This property is on the same hill as the Nugget and Mother Lode mines. The management of the Mother Lode mine is contemplating the erection of a concentrator next spring. This will be built on Sheep creek, below the mine.——The old Enterprise mine on Ten-mile creek, Slocan lake, has been leased by S. S. Fowler, Nelson, and a new drift has been started on the vein.—— About 40 tons of rich ore is ready for shipment at the Panama mine in the Kaslo district.——The Spitzee Mining Co. of this city has decided to do some development on the outcrop at the Derby claim.——The August report of the Van-Roi Mining Co., of Rossland, operating the mine of that name at Silverton, indicates that recent development of the Beryl vein has resulted in it opening in a promising manner on the fourth level for 360 ft. Average width 4 ft. 2 in., average assay 16.68 oz. silver, 6.5% lead, 11.8% zinc. The lease of the Wakefield mill having expired August 15,

the company is now building its own concentrator.——The Geological Survey of Canada has commenced the preliminary work of a survey of Franklin gold-copper camp. O. E. Le Roy and party are now on the ground. Upon the result of this survey will depend a lot of proposed development.

Rossland, October 8.

ONTARIO

The following table shows the mines, number of cars and total tonnage of ore shipped during September:

Mine.	Cars.	High.	Tons.
Nipissing	19	1	648
La Rose	6	2	234
Crown Reserve	7	2	224
Kerr Lake	7	..	210
McKinley	8	8	198
Coniagas	4	4	124
Buffalo	4	4	119
Temiskaming	3	2	101
Chambers-Ferland	3	3	96
Hargreaves	2	..	60
Standard	2	2	55
O'Brien	2	2	53
Trethewey	2	1	42
Right-of-Way	1	..	41
City of Cobalt	1	1	33
Townsite	1	..	32
Silver Cliff	1	1	28
Colonial	1	..	23
Beaver	1	1	23
King Edward	1	1	21
Total	76	35	2,371

The recent discovery in the Little Nipissing property in the Cobalt district bids fair to exceed all expectations, as the last round of shots opened a 15-in. pay-shoot in the 3-ft.

McKinley-Darragh Shaft.

vein.——At the eighth annual meeting of the stockholders of the Tamiskaming & Hudson's Bay Mining Co. the directors reported that a 20-stamp mill was being erected on the property and that the management was still trying to secure additional claims in new districts. The financial statement showed that over $500,000 had been received from sales of ore and that the outlook for the present year was excellent. The same board of directors was elected.——The diamond-drill on the Dome property at Porcupine is reported to have reached a depth of 500 ft. and the management is to install a drill with a larger capacity as the present showing is said to be excellent.——Twenty-one Cobalt mines shipped 2371 tons of ore during September, as compared with 2238 tons for August. Out of a total of 76 cars, 35 contained high-grade ore. During the corresponding period last year 16 mines shipped 67 cars, of which 31 contained high-grade ore, comprising a total of 2153 tons. Rich shipments from McKinley-Darragh, Coniagas, Buffalo, Chambers-Ferland, and Temiskaming constitute the interesting features of the Cobalt camp for September. The appearance of Temiskaming and Beaver among the shippers of high-grade ore has given an added interest to mining in the south end of Coleman. Temiskaming winze from the 400-ft. level is sunk in ore so rich that it cannot be broken.

MEXICO

CHIHUAHUA

The first unit of the Palmilla Mining Co.'s new mill at Parral is rapidly nearing completion and will be in operation before the first of the year. The plant when completed will consist of three units and handle 1000 tons of ore per day, treating custom ore as well as that from the company's properties.——The Tajo of Parral is producing about 4500 tons of gold-silver-lead ore per month and shipping approximately three-fourths of this amount.——The Parral Consolidated Mines Co. has started its 30-ton mill at the Prieta mine.——The 30-day run at the new mill of the Yoquivo Development Co., operating in the Rayon district, proved successful and the plant is in steady operation. The company is also shipping high-grade ore.

HIDALGO

The new owners of the Potosina mine in the Pachuca district who commenced work on the property last spring have cleaned out the old shaft, and the adit which was driven 200 metres to connect with the shaft for ventilation, and are to start sinking. A good shoot has been opened and it is the intention of the operators to commence blocking out the ore at once.

SONORA

It is reported that unless the Southern Pacific soon makes arrangements for the completion of its line on the Yaqui river the owners of the properties in the Tigre and Tabatalochi districts will combine forces to erect a central reduction plant.

PHILIPPINE ISLANDS

Near Ragay gulf on the Pacific side of Luzon island, a new mining district has been discovered, and is being developed. As usual in gold regions, the placers were the first to attract attention, and a company, known as the Ragay Gulf Exploration Co., has been organized to exploit the gold-bearing alluvials, probably by dredging. It is reported that bore-holes made for the company in prospecting showed the gravel to contain from 84 cv. to ₱2 per cubic yard. In addition to the placers the company owns a number of veins carrying copper. Coal has also been discovered and locations made. The Stanley dredge was busy throughout June and recovered 140 oz. of gold. Low-grade ground is being dredged. Better gravel is known to lie beyond. The Paracale Gold Dredging Co. has temporarily suspended operations, pending the completion of a new dredge, which is about finished. The quartz mill bought by this company has arrived. Johnson and Carman have secured for American capital several thousand acres of placer ground in Nueva Ecija. Engineers are expected to soon outline a plan of operations. The Tellus company has allowed its option on the Mancayan copper property to expire, in consequence of which the Lepanto Mining Co. will reorganize to equip and operate these mines, which are the largest known at present in the Far East.

A vein over 20 ft. wide assaying $10 to $25 gold per ton has been cut on the property of the Headquarters Mining Co. in the Benguet district. All the machinery for the mill is on the ground and construction is to be started at an early date. The plant is to be completed by next April or May.——Good reports have been received regarding the development at the Navotas and Malapayunang groups at Mambulao near Paracale.——G. I. Adams, geologist of the Division of Mines, has resigned and will engage in consultation work in the Islands.——The Secretary of War has decided that the work on the Government coal mines at Batan shall be suspended unless Congress makes an additional appropriation.——A 3-ton shipment of high-grade ore has been taken from the Little Wonder mine. This is to be forwarded to San Francisco for treatment.

Company Reports

MONTANA-TONOPAH MINING COMPANY

The annual statement of the Montana-Tonopah Mining Co. for the fiscal year ended August 31, 1910, shows a total of 50,245 tons mined and milled of an average assay value of $15.22. The total receipts per ton were $12.94, and the total expenditures per ton were $10.26, leaving a profit of $2.68 per ton, or a total yearly profit of $134,715.40. The expenditure of $10.26 per ton is subdivided as follows: mining, $3.41; development, $1.81; milling, $3.73; general maintenance, indirect charges, etc., $1.31. The energetic management of the company is indicated by the showing of 10,681 ft. of development. The cost per foot of this work, exclusive of compressed air and general charges was driving $6.24, cross-cutting $5.83, raising $5.10, and sinking $14.43. Of the development 42% is classed as 'development on possible milling ore. The 40-stamp mill averaged 38½ stamps, with a daily tonnage of 3.67 tons per stamp. The average value of the mill tailing was $1.43 per ton, giving a gross extraction of 90.8%—a gold extraction of approximately 93% and silver 90%. Of this extraction 37½% was in the form of concentrate and 62½% in bullion. The average fineness of the bullion was 11.6 in gold and 890.6 in silver. The concentration ratio was 50 tons to 1. The milling costs for the last six months were but $3.37, due to the previous repairing and overhauling of the Butters filters and the increased efficiency under the new superintendent, B. A. Bosqui. Within the year the company began purchasing its water from the Tonopah Mining Co., being water pumped from the Mizpah shaft and entirely suitable for milling purposes. In comparison with the previous year the profits are slightly larger. The grade of the ore has been better, but mining and development costs have shown an increase. Milling costs showed a slight reduction, mainly in the item of power, due to the avoidance of excessive 'peaks.' As a whole, the creditable showing for the past year is due to Edgar A. Collins, superintendent, and to W. B. Alexander, the secretary-treasurer of the company, who makes his office at the mine.

ORIENTAL CON. MINING COMPANY

The report of the Oriental Con. Mining Co., operating in Korea, for the year ended June 30, 1910, shows that total receipts for the year were $1,434,494.86; operating costs were $780,258.83; profit, $654,236.03; put back into new construction, development work, etc., $30,559.08, leaving net receipts for the year $623,679.94. The statement is made by Alf. Welhaven, the general manager, that the average value of the ore was somewhat lower than during the previous year, the increase in net profit of $67,307.20 being due to increased tonnage, smaller construction expense, and lower cost of mining. Seven mines were operated, the total tonnage being $319,885, from these mines, to which 822 tons was added, being the product of several tribute mines. Mining cost was $1.415 per ton, which includes all underground development during the year. This cost was 17.5c. per ton less than the previous year. The total footage driven was 27,189 ft. There was a total of 240 stamps operated during 325 days 13 hours and 34 minutes. The duty per stamp was 4.3 tons. Total ore reserves are estimated at 838,250 tons, valued at $3,948,475. This shows an increase in ore reserves for the first time since 1904. The company distributed as a bonus to white employees on Christmas Day, 1909, $10,000, this being the fifth annual distribution of this character. The report is, as usual, given in detail, leaving little to the imagination of stockholders. Among notable features of the company's operations during the year were the fact that less money was put back into construction than in previous years; the operating expenses were 28.5c. per ton less than during the previous year; the development footage was the largest in the history of the company; ore reserves were increased, and ten stamps were added to one of the mills. It is expected that the tonnage mined and crushed this year will be larger than ever before.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

SUFFICIENCY OF LOCATION NOTICE

A notice of the location of a mine is sufficient whereby any reasonable constructions, in view of the surrounding circumstances, the language employed in the description will impart notice to subsequent locators.

Snowy Peak Mining Co. *v.* Tamarack & Chesapeake Mining Co., (Idaho) 107 Pac. 60, Feb. '10.

ASSIGNMENT OF MINING LEASE

A provision in a mining lease requiring the approval of the lessor to any assignment cannot affect the liability of an assignee for the expenses of operating the mine where the lease was delivered to him, as he must have contracted in reference to such stipulation.

Hummer *v.* McGee, (Wis.) 124 Northwest. 302, Jan. '10.

ADVERSE SUIT—RECOVERY

The plaintiff in an adverse suit must recover upon the strength of his own title, and not by reason of the weakness of the title of the applicant for patent; and the fact that a third person has made a subsequent location of all or of part of the territory covered by the location for which the patent is sought will not avail the plaintiff in such adverse suit, not based upon such subsequent location.

Snowy Peak Mining Co. *v.* Tamarack & Chesapeake Mining Co., (Idaho) 107 Pac. 60, Feb. '10.

CONSTRUCTION OF LOCATION CERTIFICATE

A location certificate using the word 'location shaft' instead of 'discovery shaft' in giving the length of the claim in each direction, while the point from which the length was measured in the certificate of an enjoining claim was designated as the 'location,' was construed as intending to give the length each way from the centre of the discovery shaft as required by the statute, and that the 'location shaft' in one certificate and a 'location' in the other referred to the discovery shaft.

Bergquist *v.* W. Virginia-Wyoming Copper Co., (Wyo.) 106 Pac. 673, Feb. '10.

FORFEITURE OF MINING CLAIM—FAILURE TO PERFORM ASSESSMENT WORK

A forfeiture of a mining claim does not take place by the mere failure of the locators to perform the assessment work for any particular year. But to complete the forfeiture there must have been a re-location of such ground before any resumption of the assessment work takes place, as the right of the original locator is terminated only by the entry of a new location, and resumption of work prior to the lawful inception of an intervening right prevents forfeiture.

Snowy Peak Mining Co. *v.* Tamarack & Chesapeake Mining Co., (Idaho) 107 Pac. 60, Feb. '10.

LEASE OF MINE—FORFEITURE

A lease of a coal mine provided for its forfeiture for non-payment of rent. The lessee after operating the mine failed to pay the stipulated rent and the lessor brought an action to forfeit the lease. On proof that the lessee was insolvent and it appeared doubtful whether the mine developed by the lessee at a large expense could be so operated as to pay the rent, and where it appeared also that liens were asserted against the property, a court of equity properly terminated the lease in favor of the lessor, notwithstanding the rule that equity will relieve against forfeitures when circumstances justified.

Wender Blue Gem Coal Co. *v.* Louisville Property Co., (Ky.) 125 Southwest. 732, Mar. '10.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

ALGERNON DEL MAR is in San Francisco.

L. A. JEFFS, of Salt Lake, was in Humboldt county, Nevada, last week.

P. O. ARGALL has returned from a vacation at the Hawaiian Islands.

SCOTT TURNER was in San Francisco on his way from Angels to Mammoth.

OSCAR LACHMUND, formerly of Salt Lake, is now at Alamos, Sonora, Mexico.

C. L. COLBUAN has gone to Arizona to examine the Oro mine near Crown King.

CHARLES JANIN has gone to Plumas county, California, on professional business.

ARTHUR L. PEARSE was in San Francisco this week, and will return to London at the end of this month.

E. R. BUCKLEY has gone to southern Idaho, where he will be for a couple of weeks before returning to Rolla, Missouri.

O. OVERSTROM, consulting engineer for the Calaveras Copper Co., has been in San Francisco on his way to Copperopolis.

F. CURTIS is in San Francisco from Smelter, Nevada, where he has charge of sampling and experimental work in the Steptoe concentrator.

WILLIAM R. JEWELL passed through San Francisco on his way to Bakersfield, from Plumas county, where he has been examining placer mining property.

S. E. BRETHERTON was at the Afterthought mines, Ingot, this week, and will be at the Dominion Gold Mines, in Plumas county, California, next week until the 25th on professional business.

J. A. HOLMES, the Director of the United States Bureau of Mines, was given a compliment dinner at the Palace Hotel, October 6, by the San Francisco Section of the Mining and Metallurgical Society of America. Among those present were J. A. HOLMES, S. B. CHRISTY, R. W. BROCK, F. G. COTTRELL, G. S. RICE, S. E. BRETHERTON, E. H. BENJAMIN, R. S. RAINSFORD, E. A. COLLINS, J. R. FARRELL, R. C. SHAW, C. C. BRAYTON, J. W. MALCOLMSON, L. M. MILLS, GELASIO CAETANI, A. E. MONTGOMERY, RALPH ARNOLD, H. F. BAIN, E. T. BLAKE, SUMNER S. SMITH, A. C. LAWSON, HERMAN ZADIG, FRANCIS DRAKE, E. C. HUTCHINSON, T. A. O'DONNELL, M. L. REQUA, ALFRED VON DER ROPP, J. H. MACKENZIE, F. W. BRADLEY, C. C. DEBBY, CHAS. G. YALE, C. H. LINDLEY.

OBITUARY

J. W. MILLER, who was among those killed in the wreck on the Illinois Traction System near Staunton, October 4, was general manager for the Superior Coal Co., having mines near Gillespie, Illinois, and one of the best known operators in the Middle West. Mr. Miller served several years as State Mine Inspector in Iowa, resigning to enter the service of the Consolidated Coal Co., affiliated with the Chicago & Northwestern railroad. When the Superior Coal Co. was organized in Illinois to furnish coal to that railway, Mr. Miller was placed in charge. Here he did remarkable work, sinking shaft No. 1, 350 ft., opening the mine, and hoisting 3000 tons of coal in 8 hours, all within a year of breaking ground. Later at mine No. 3 he hoisted 3619 tons in one shift, and on the same day took 3601 tons from shaft No. 2. Mr. Miller found time for public service as well as for his private work, being one of the influential members of the Illinois Coal Operators' Association and having been appointed this year on the State commission to organize mine-rescue work. For this position he was peculiarly well fitted, since he had to an unusual degree the confidence of operators, miners, and inspectors. His death is a loss to the State and the industry as well as to his friends and the company for which he worked.

THE flotation processes, which had their birth in Australia, and have thus far found their principal application there, are undergoing a strenuous investigation in the courts with a view to determining the respective rights of the various inventors.

A recent annual government report of Victoria, Australia, on the mining industry makes the interesting statement that the fatal accidents in metal mines was low, being 0.80 per 1000, and that none were killed in the coal mines during the year.

THE Aleutian islands are again the scene of volcanic activity, vessels from that extreme westerly possession of the United States bringing information to that effect. It is not uncommon for good-sized islands to disappear within a few hours from the Aleutian chain, nor for new ones to make their appearance.

FOURTEEN feet of ore assaying ten ounces gold per ton is a promising prospect, particularly when taken at a depth of 80 feet from the surface. This is what is claimed for the Bullfinch mine at Southern Cross in Western Australia. That region has already produced some astonishing mines, and the Bullfinch may belong to this class.

A BONUS of $10,000 gold is paid annually to its white employees by the Oriental Consolidated Mining Company, operating in Korea. This has been done for the five years past on each Christmas Day. It is a splendid recognition of the faithful services of the engineering staff and assistants, which other successful companies whose profits are wholly due to their men might follow to advantage.

ELSEWHERE herein will be found a somewhat novel theory of the distribution of ore shoots in veins, which will doubtless be read with interest by mining men and geologists. Whether the theories there expressed are correct or not, there are many places which seem to bear out the ideas. We hope those who may have given this matter any attention will contribute to the general knowledge on the subject, for it is only by collating the results of the observation and the opinions of the many that we can arrive at the truth.

AN interesting phase of industrial activity in Massachusetts is the attempt of certain corporate interests to have the Gas and Electric Light Commission grant to electric power companies the Right of Eminent Domain, in that State, claiming that such

procedure would greatly cheapen the cost of installation of power transmission lines. Nothing has as yet been heard of any similar movement on the part of large power distributing companies in the West, but if the entering wedge is successfully introduced in Massachusetts a precedent will have been established which would have important influence in forwarding a similar attempt here. There are two sides to the question, of course, but it is difficult to see in what way electric-power distributing companies, which are entirely private enterprises, are entitled to the privileges which the Right of Eminent Domain would give them. Under strict supervision abuses of the privilege might be avoided, but the much desired strict supervision is often a most difficult thing to secure.

NOTABLE progress has been made during recent months in tunneling on the Los Angeles aqueduct, according to the annual report of the engineers to July 1, 1910, recently issued. During May the Elizabeth tunnel was driven from the north portal 567 feet under direction of John Gray, and in April the heading from the south portal was advanced 604 feet under W. C. Aston. The latter run is claimed to be a new American record for tunneling. The difference between the accomplished results in these two instances practically represents the difference in working conditions and in the material passed through. The south portal drains by gravity, the water in the north end being pumped out to the tunnel entrance. The north end also required considerable timber support, with close lagging, whereas very little timbering was necessary in the south end, permitting more rapid progress. Another item of interest, and one seldom observed under similar conditions elsewhere, is that as these headings have advanced the cost per foot has decreased, instead of increasing, as would be the natural supposition. Up to the date of the report, 10,810 feet had been driven from the south portal and 10,705 feet from the north portal, leaving 5345 feet to be completed. Of this, about 3000 feet must have since been completed, if the miners have been able to keep up the rate of driving. The work being accomplished in the Elizabeth tunnel of the Los Angeles aqueduct, and that in the Laramie-Poudre tunnel, Colorado, is setting a rapid pace for those engaged in driving tunnels in any other region, which will be hard to excell.

A Great Mine

Among the famous ore deposits of the world is the Broken Hill, in the Barrier range, New South Wales. The most important property on this huge deposit of lead-zinc-silver mineral is the Broken Hill Proprietary. The company was organized early in 1885, and has since paid 153 dividends aggregating $42,447,000. In addition to these direct dividends derived from profits of ore production, stockholders in this fortunate organization have received $13,641,000 more from leases and interests in neighboring properties, share sales, and from other sources, making a total of profits amounting to over $56,000,000. The mining methods in vogue at Broken Hill were introduced by American mining engineers, or are the result of evolution of earlier American methods. Among the pioneers were W. H. Patton, of Comstock fame, and F. F. Thomas, formerly of the United Verde, of Arizona, and later of the Kennedy gold mines, California. These men introduced a number of American practices, new to Australia, and made it possible to work the great deposits in a safe and economical manner. The present manager of Broken Hill Proprietary is D. G. Delprat, formerly manager of large mines in Spain, where he introduced novel methods of stoping large orebodies without the use of timber. Mr. Delprat is a progressive miner, and believes in encouraging his men, not only to work but to think. In line with the latter idea he has posted about the works a card which asks employees to make any suggestion which in their opinion will facilitate work and reduce expense. Such communications, addressed to the manager, are deposited in a locked box, provided for the purpose. It is needless to add that suggestions coming through this channel from employees receive consideration, and the man submitting valuable ideas is not forgotten by the management.

The Factor For Safety

Many mining engineers, and more particularly the younger members of the profession, appear to consider it necessary, after having made a careful mine examination, to discount the results of their work in making up their reports. This 'factor for safety' ranges all the way from 10 to 30 per cent, or more, depending upon the degree of confidence—or the lack of it—that the engineer has in his own ability to arrive at correct conclusions. He obtains his information by the most painstaking methods, or he should do so, and his work, if properly done, ought to give accurate results. He has had caution, accuracy, and thoroughness drilled into him for years, and he undertakes his professional work with these precepts constantly in mind. Yet, after having accomplished the task of a mine examination in a manner to satisfy his most exacting ideas of what is proper in his conduct of this line of investigation, he discounts his report, that he may be 'on the safe side.' This is a proceeding which he has not been taught and which is not found in the curriculum of any college or mining school.

The entry of this 'factor for safety' in the mining report is not only an injustice to the intelligence, integrity, and care of the engineer, but is even a more serious injustice to his employer, whatever may be the relation of the latter to the property—whether he be the owner, a prospective buyer, or merely acting as an agent for either side. If the mine is sufficiently developed to make the collection of accurate data possible, this information forms the basis for a reliable report, and there should be no factors for safety introduced by the engineer making the report, except as to such portions of the mine as were either inaccessible or undeveloped. In describing such portions of the property a statement to the effect that an examination was impossible, owing to—giving the reason—should be made, and this should suffice.

The Deadly Strap-Iron

A fatal accident occurred on October 12 at the South Eureka mine at Sutter Creek, California, whereby two men lost their lives. Five men were being hoisted, three of whom were down in the skip, two riding on the draw-bar. It was the latter who were killed, their companions beneath them being unharmed. This accident was almost identical with one that occurred last spring at the Central Eureka mine, which joins the South Eureka. In that instance two men lost their lives in exactly the same manner and from the same cause. The projecting end of a length of strap-iron track, which, becoming loosened, turned upward, and it is believed was caught by the lip of the skip, and wrenched from the timber, to which it had been spiked. The loose strap of iron swept the two men from the draw-bar before they could secure a more firm hold, and they fell from a point near the 700-foot level to the bottom of the shaft, a distance of more than 2000 feet. As the shaft is sunk at an angle approximately 60 degrees, there was no possibility of their escape from death.

The main shaft of the South Eureka mine is but one of a large number on the Mother Lode of California which is sunk for the greater part of the way in a fissure or in 'swelling ground.' The rocks in and near the fissure swell upon exposure and cause the timbers of the shaft sets to move, rendering the use of heavy T rail extremely dangerous, as a movement of the timber sets is likely to result in causing the end of a rail to project above the end of that adjoining, and a rapidly moving skip is very likely to be derailed upon passing such obstruction. Strap-iron, being of lighter weight and of different cross section, bends more readily and has therefore been generally adopted for use in shafts of this type. While less dangerous than T rails the strap-iron tracks have already cost the lives of many men. The reason is to be found in the fact that the shaft timbers are permitted to shift for many a day, menacing the lives of the men constantly, until finally it becomes suicidal to permit them to longer remain without repairs. Moreover, the straps—originally three inches wide and three-quarters of an inch thick—are worn down by the passage of thousands of skip loads of rock, timbers, men, and supplies; the spike holes become worn by the vibration of frequently passing wheels, and corroded by rust. The spikes themselves are reduced in size from the same cause, until, finally, the end of the strap escapes from its fastening, slipping over the end of the spike, and then death lies in wait for the first unfortunate who may pass. This is no doubt exactly what happened at both the Central and the South Eureka mines. This element of grave and constant danger has long since been recognized, but the men become so accustomed to it they no longer fear, until a fatality occurs which results in repairs and rigid shaft inspection—for a time, until their temporary timidity disappears, when things drop back into the same old groove. It is to render such shocking accidents as these less numerous, and to prevent them if possible, that the Bureau of Mines was created, and we believe that its labors will result in a noticeably important decrease in the number of mine accidents and the percentage of fatalities.

Stamp-Duty on the Rand

For years past the stamp-mills of the Rand have led the world in output per stamp. Originally crushing from five to six tons per stamp each twenty-four hours, coarser screens and heavier stamps were introduced to increase the stamp-duty until it reached nine or more tons per stamp daily. Recently, at the East Rand Proprietary, experiments have been made of a radical nature, which may greatly change metallurgical methods, by vastly increasing the tonnage crushed per stamp. These experiments have been carried on at the Cason and Angelo mills, and it is stated present indications are that the stamp-duty will be increased to twenty-five tons daily per stamp. The number of tube-mills is to be increased to one for each ten stamps. These mills have 220 stamps each, and will therefore require, when fully equipped, forty-four tube-mills. It is contended that by this method of operating—crushing with stamps through three-eighths inch mesh, and sending this product to tube-mills, at the rate of twenty-five tons daily per stamp—the expense of power will be reduced fully fifty per cent. At this rate each of these mills will have a crushing capacity of 165,000 tons monthly, or a total for both of 330,000 tons per month. This, however, is considered as beyond the present capacity of the mines, which, by the way, comprise a very large area, but it is proposed to install a sufficient number of tube-mills to bring the output up to 200,000 tons monthly, which would be equivalent to over 6600 tons every twenty-four hours, and would be the largest tonnage output of any gold mine in the world, exceeding the tremendous output of the Homestake of South Dakota by 2600 tons daily.

An interesting problem is presented in contemplation of the ambitious plans of this Transvaal mine management, and that is the ability of the mines to supply this large tonnage continuously for a considerable period. At the beginning of 1910 the East Rand Proprietary Company owned 4312 claims, and early in the year opened negotiations with the Transvaal Government for the right to mine under 169 additional claims, consisting of township, water-right, and other lands. At the beginning of the year ore reserves were estimated at over 11,000,000 tons, having an average value of $5.75 per ton. The width of reef is variable, but as nearly as can be determined from consulting the latest authority on mining in the Transvaal, *Mines of Africa*, the width is from 24.4 inches to 29.2 inches, on which the total development exceeds 84 miles. To December 31, 1909, the total tonnage extracted had exceeded 7,928,000 tons. In any event, notwithstanding the great claim area, extensive development and vast ore reserves available, the constant production of 6600 tons of ore daily, as contemplated, is a proposition which will require all the skill, energy, and good fortune which may fall to their lot, but the Rand is a country of large possibilities.

Hints to Ore Shippers

By S. E. Bretherton

*Until within the last few years I was connected with custom lead and copper smelters—altogether for more than 25 years, acting as general superintendent and metallurgist, much of the time in charge of mining properties, shipping to the same or other smelters, which gave me an opportunity to view the situation from both sides. Mistakes would occur for or against either side, but these mistakes were mostly clerical; in fact, I don't remember of any firm with which I have been associated, attempting to cause improper returns to be made. No doubt in past years there has been crooked work at some smelters and custom sampling works, but this was an exeeption to the rule. The custom smelters do not have to resort to improper methods if they know their business. It is to be expected that they take the benefit of a doubt in their own favor, the same as in any line of business, and with this the miner does not find fault, if it be not carried to excess. It is sometimes diffieult to get those who are making their first shipments to understand the reasons for penalizing the different so-called refractory elements in the ore; such penalties being added to the regular charge for treatment. Part of the smelting business is knowing how to get the proper ores so that the metallurgist can make suitable mixtures and thus reduce the amount of flux to be purchased. Every pound of barren flux which has to be smelted, of eourse, displaces that much ore on which the smelting company would otherwise be able to charge for treatment. Smelter rates are published frequently in the technical journals. Some of the profits are made by mixing the excess zinc, barium, silica, or alumina of one shipper's ore with the elean ore sent in by some other shippers.

Taking moisture samples, although apparently simple, is really one of the most difficult matters. To ship and crush a lot of ore before taking the moisture sample would result in allowing moisture to escape before the sample was taken. To weigh a lot of lumps in the moisture sample would be wrong, as the moisture they contain would not be dried out at the temperature of the water-bath which is used for drying the moisture samples, so for convenience and safety the boy taking moisture samples usually selects more than the average of the fine, taking about 50 oz. from the freshly exposed parts of the ore pile as soon as possible after the lot has been weighed. The sample is immediately weighed, and dried for 24 hours, the loss in weight being considered as moisture. To satisfy the mine representative, on several oeeasions this method was checked by drying several entire wagon loads for a week on steel plates over the roasters with slightly higher results than the daily averages. Several times when purchasing copper ore from men experienced in other lines of business, it took some time to explain that after deducting the weight of the moisture from the ore before settling (the ore represented by the weight paid for should be as dry as the sample pulp on which the value is determined), that 1.3% copper had to be deducted from the wet copper assay, as reported on the assay certificate; and that 1.3% was deducted from the eopper assay when we sold our matte to the refinery. Occasionally the coarse ore eontains the most moisture, as when it is of a porous or spongy nature, and especially when it contains manganese.

The question of aceuraey in taking the regular sample to determine the amount to be paid is important. Some prefer hand-sampling, while others prefer automatic sampling. When the ore is sampled by hand, that is, by taking out a certain percentage for samples as the workmen remove the ore after it is crushed to a suitable size—not too small for smelting, the men are supposed to throw out ore of an average. Often they are careless and they require constant watching. This method of sampling is expensive. I like to have the mine representative on hand, for if he will constantly watch the lot being sampled it is a protection to the buyer as well as the seller. On the other hand, most automatic samplers are only suited for sampling accurately sueh material as concentrate, or ore, after it is crushed finer than is necessary or suitable for smelting in blast-furnaces, as explained in my article on automatic samplers in the *Mining and Scientific Press* of November 28, 1903.

With all the chances there are for making mistakes in determining the value of ore, it is remarkable how accurately its value is determined and how closely different sampling works that follow correct principles will check each other. I have shipped rieh ore, concentrate, and copper matte, sometiines containing 30 oz. of gold per ton, to the smelters at Pueblo, San Francisco, New York, and Salt Lake, always sampling and assaying before shipping, and it was seldom that we had to ask for a re-sample. Often we would call for a re-assay, as some of our contracts would not permit a settlement unless the assayers agreed within $1.25 per ton in the combined averaged differences of the metal value. When preparing the sample pulp for assay from ore containing metallic gold and silver, the shipper often thinks he is defrauded out of metallics caught on the screen, when quite as likely, he is not, for it is surprising how the metallics will grind up and work through the sieve with the pulp; but where there is any doubt, all particles remaining on the screen should have lead added, be cupeled, and the results, if any, added to the assay in proper proportion. All this has some bearing on smelter rates, as it is generally thought by the public that part of the smelter profits are derived from such sources, which is quite true, but not to the extent commonly supposed.

The question of 'salting' has also to be considered, the risk being nearly all against the ore purchaser and in favor of the ore seller. It would not be a difficult task for the shipper, or his representative, if he is given a chance, to drop, say 1% of gold or silver into the few ounces of the sample pulp near the end of its preparation (1% equals a fraction over 291 oz. per ton, so that 0.1% would equal 29.16 oz.,

*Presented to the American Mining Congress at Los Angeles.

equal in value to $583 per ton, if gold were added). It would be impossible to decrease the value in the same way by adding anything. There is another danger of salting, especially where automatic samplers of the ordinary type are used, by small rich lots of ore salting samples from large lots. Large portions, and perhaps all of a small rich lot of ore is crushed and rolled fine and treated all the way through as a sample. The metallies, tellurides, chlorides, etc., of gold and silver will gather in the crevices by being ground in and sticking to the machinery and are seldom thoroughly removed by cleaning before the same machinery is used to finish a sample representing one-twentieth of a lot of several hundred tons and of perhaps one-twentieth the value per ton. A salting of only 50c. per ton of the large lot sample would mean a heavy loss. This is one of the objections to handling small lots; another is that the labor and expense of sampling and assaying a small lot of ore is nearly as great as though the sample represented several hundred tons. Experience teaches that the loss in gold is much greater when smelting rich gold ore than when smelting ore containing little gold. In fact, there is often more gold recovered when smelting ore containing low gold value than is accounted for by the assays. In the usual schedule of smelter rates a lower price per ounce is offered for gold in low-grade ore than in that which is high-grade. The only reason I can give for this is that there is less gold on which to make a profit. The Western smelters do not get all this profit. They usually pay from $18 to $20 per ounce for gold and sell it for $19 to $20 per ounce when marketing copper matte, but get more for both gold and silver when marketing it in lead bullion. There are good reasons for this: the loss in gold being so much greater when refining copper matte than when refining bullion, the refiners have to buy accordingly.

The metallurgical loss on silver is much greater than on gold. Lead custom smelters, with good practice, make considerable on the gold and silver, but the custom copper smelter, bidding for silver ore in competition with the lead smelter, suffers a loss. It is the custom to pay for 95% of the silver content at the New York quotation, re-sell the same silver in copper matte, less 5%, which leaves the metallurgical loss (anywhere from 2 to 5%), an actual loss against the treatment charged. With copper there is a gain in a metallurgical way with a custom smelter, as the practice is to deduct 1.3% from the wet assay, the actual copper content. Suppose the ore purchased contained 2.6% copper, the smelter would deduct the 1.3%, equal to 50% in this case, whereas, the actual loss should not be greater than 5 or 6% of the real content of the ore. On lead, like silver, the metallurgical loss is much greater than with either copper or gold, which accounts for the smelting company not paying for more than 90% of the lead by dry assay (the dry assay for lead being made either by the regular fire assay, or 2% is deducted from the wet assay). For convenience, where the ore is not too refractory, lead assays are made by the fire method.

After considering the losses and gains on the metals to be marketed, such as gold, silver, copper, and lead, which have some bearing on smelter rates, take into account the elements which enter into the cost of smelting, such as manganese, iron, lime, and magnesia, on the credit side, and zinc, sulphur, silica, alumina, barium, and arsenic on the debit side. At some of the copper smelters, in Shasta county, California, silica is placed on the credit side, due to the fact that the copper ore in that vicinity contains little silica and a large excess of iron, so that the smelting companies have to make rates to suit local conditions. The shipper, when sending in a lot of siliceous ore, at, say $5 treatment per ton (neutral basis rate), is disappointed, if he is not experienced, when it comes to final settlement, for if the ore contains, say 75% silica, 13 alumina, and 2 iron, the alumina should be added with the silica, making 88% insoluble. (The metallurgist may later call for a fused silica for his guide in figuring ore mixtures, for the 'insoluble' deducted by the smelters as 'silica' may contain alumina and barium-sulphate, the latter more objectionable than the silica itself, which he has to figure in his calculation on a different basis.) Crediting 2% iron leaves 86% silica to be penalized, at 10c. per unit, this amounts to $8.60 per ton to be added to the treatment of $5 per ton, a total of $13.60 per ton for treatment. Such penalty creates a hardship on the shipper of siliceous ore, yet, on the other hand, if the same man sends in a lot of ore containing 10% silica and 60% iron, the excess iron over silica is 50%, which at 10c. per unit amounts to $5, which credit deducted from his nominal rate of $5 leaves no smelting charge. This is a high premium for the iron; but suppose the metallurgist has to purchase barren iron ore for flux, containing 64% iron and 4% silica. In practice, it requires approximately 2% of iron, or its equivalent, to 1% silica, the actual excess of iron would be only 56%, equal to 28% silica, in regular lead smelting practice. The smelter gets $2.80 from the 28% of silica penalty, whereas 64% iron usually costs double that amount. This helps to explain why there have been so many smelting company failures. The copper metallurgist has the advantage in being able to make a more siliceous slag, 1% iron being equal approximately to 1% silica, but if it is a small plant and the matte is shipped, instead of being converted locally to metallic copper, this advantage is mostly lost by the iron being shipped in the matte. It is difficult, in fact almost impossible, to explain all of these 'give-and-take' points to the shipper.

Now as to the penalties on sulphur or zinc. Barium is weighed with the silica usually as insoluble. Too much zinc causes trouble in three ways: first, by volatilization, carrying off silver; second, by helping to form incrustations on the walls of the furnace; and last, but not least of the troubles, making a viscous slag. By mixing the ore containing too much zinc with enough clean ore this trouble is avoided; but why should the shipper of ore containing excess of zinc, get the benefit of this mixing any more than the shipper of siliceous ore should get the benefit of ore containing excess iron shipped by some one else, or the benefit of the mixtures made at the smelters by

the experienced metallurgist, where the company must hold large stocks of ore, tying up much capital on which interest has to be paid, until such time as ore to make suitable mixtures can be secured?

Even in a mining district like Leadville it was necessary to carry a large ore supply, the average character of the ore, sometimes changing in a few months from an excess of silica to an excess of iron. Then silicious ore was shipped in from the southern end of the State. For years it was a case of 'dog eat dog' with the smelters, each one daily hoping the other would close down and quit the business first. The close competition among the Colorado furnaces for ore was a great benefit to the miner, but a serious matter to smelters. This unhealthy state of affairs could not last and the fight meant the survival of the strongest until there was left in Leadville only two lead smelters running in the fall of 1893, from the thirteen in and around Leadville in 1879. It was a wise move on the part of the conflicting smelting interests in the West when they agreed to combine into practically one company. It not only did away with competition—it did away with the greater part of the fixed expenses, such as numerous superintendents, metallurgists, ore buyers, engineers, etc., and reduced the management to a few of those who had the most ability combined with personal influence. The smelting combination thus formed enabled them to increase the smelting charges to the shipper, but not as much as one would expect, nor was it necessary. The advantages gained by having only to operate a few plants to treat the same amount of ore, the exchange of ore between the different plants to get suitable smelting mixtures, improving and operating only those plants which could treat the ore to the best advantage, are so great that the smelting combine can give the miners lower rates than were possible with too many independent smelters and still make good interest on the value of all the plants (both idle and operating), that went into the combine.

I do not wish any one to infer that I am defending any 'smelter trust.' On the contrary, it fell to my lot to be next to the head, and part of the time at the head, of smelting companies that had to compete with the organizers of the so-called 'smelter trust,' and the trust itself for years. Reasonable competition is necessary in all classes of business. There is still a limited field for smaller smelting enterprises where they are protected by long railroad hauls, or by distance from the railroad, especially if they adopt high concentration and ship out rich products.

There is one phase of the business the public does not appreciate to its full extent. That is the change in the value of metals. One would naturally suppose that if the prices go down and then up again, the averages would protect the purchaser, but such is not the case. High prices mean a greater number of mines producing and much larger ore stocks being carried on which to lose, than is carried in stock with low prices and small production. I remember at the American Smelting Works, at Leadville, in 1893, there was about the largest stock of ore on hand ever carried when silver took its remarkable drop in price, the price of lead also dropped in sympathy. Those who are in the custom copper smelting business had a similar experience in 1907. If the smelters and refiners could be assured of a stable price for metals, even if that price were low, they could afford to make the treatment charges lower. Under ordinary conditions there is a profit made on all the metals treated in addition to the regular reductions for treatment. There is also a profit on the penalties charged for sulphur and arsenic, not so much in lead smelting as in copper smelting; in fact, in some cases, one of the most serious troubles is lack of sulphur to save fuel and to form matte in the copper-matting furnace. There is no advantage in having arsenic in the ore under any circumstances, but with copper smelting the penalty is usually too high. Several years ago a friend of mine wrote me that the smelters were deducting about $6 per ton from the assay value of his ore for arsenic penalty and adding that much to the regular treatment of his copper ore. I explained to him by letter why they should not make such a charge. Afterward he wrote me that my letter enabled him to have the penalty on arsenic removed. Often the ore shippers themselves are to blame; they may not know all the points in connection with making a contract for ore settlements; they are expecting to be cheated and perhaps demand a higher price for some metal their ore contains than they are entitled to. If the shrewd ore purchaser allows it, he catches the seller on something else. What the mining and smelting industry needs is more uniform prices for the metals. This can only be obtained by the Government taking the matter in hand and publishing monthly a statement of total stocks on hand held by every one. This would prevent the large producers either under or over-estimating their stocks to disturb the market in order to create unnatural prices for their own benefit. The question of smelter rates must be settled between the seller and buyer.

The adjustment of penalties charged by the different smelters, and prices paid for the metals should also be left for the present to be settled between the miners or their representatives and the smelters themselves. Each locality is different and requires different rates. No doubt it would be to the advantage of the miners of each district to combine and employ a competent person to make contracts and settlements for them. A saving of only $1 per ton would be worth considering. The smelting companies would rather deal with a few who understand their business than a greater number who do not.

General Manager Scott of the Siamese Tin Syndicate, Ltd., in his report for the year 1909 of investigations made by him makes the statement that one prospect has been examined that looks promising, covering about 280 acres of ground with a depth of 34 ft. and averaging approximately 19c. gold per cubic yard, and expects a report favorably on an additional 350 acres upon which boring is now in progress. He believes the company may rely on at least £600,000 worth of tin that may be worked at a profit. There are other prospects, but only one or two have been worked at a profit.

Gold Mining in Randsburg Quadrangle, California—II

By Frank L. Hess

(Continued From Page 509)

Orebodies.—The gold deposits in the Yellow Aster mine are typical of those found in many other mines of the vicinity. There are three types: 1. Deposits along faults in crushed schist and granite. 2. Stockworks in granite. 3. Fissure veins, with more or less quartz. In only two or three other mines of the area is there more than one type of gold deposit, and no other has all three types. The three types, though distinct for the most part, in places grade into each other. Very little visible gold is found in the mine, and that little is mostly in small particles. There is a remarkable lack of other metallic minerals. A little pyrite and arsenopyrite, iron oxide derived from

Yellow Aster Mine and Mills, Randsburg, California.

them, and some scheelite are the only ones certainly identified, though it is reported that some pannings show a heavy mineral of a light-yellow color which may be wulfenite.

Fault Lodes.—The faults were probably caused by the stresses accompanying the intrusion of the granite. They are probably nearly all normal or gravity faults, but the amount of movement is not known in any ore-bearing lode. The movement has been, in each fault, in different directions at different periods, and these directions vary from vertical to horizontal. On the Rand level the main fault is followed by the Jupiter drift, running N. 80° W., with many minor curves and variations in its course. The gulch cuts through the fault at the Rand level, where the fault turns and runs about S. 70° E. The dip is from 27° to 44° to the north and east, but it is less toward the bottom of the workings, 300 ft. below the Rand level. The dip is wavy, as is the strike of the fault.

The fault is slickensided in many places, and accompanied by crushed material from 2 to 80 ft. thick. The greatest thickness is in the 100-ft. level. The rock is not all crushed fine, but the fault branches with finely crushed material along each part, and the rock between the lesser faults is badly broken. The fault cuts both schist and granite. In both rocks the comminuted material along the fault is so fine and decomposed that in many places it is almost impossible to tell whether the material is schist or granite. As would be expected there is great shattering of the rocks and many minor faults with much slickensiding. A great deal of work has been done along the fault. Various levels and stopes follow it to the top of the mountain, and below the Rand level four levels were worked. The amount of ore extracted decreased as the depth increased, and little was done on the fourth level. Below the third level the quantity of crushed material along the fault decreases considerably, iron and arsenical pyrites appear, and gold decreases.

Below the Rand level large chambers were taken out in granite lying in the fault zone. One square-set stope on the first (100-ft.) level was over 100 ft. long, 50 ft. wide, and probably 40 ft. high. The gold in this stope is said to have been coarse, in places reaching the size of wheat grains. The ore is thought to have averaged $10 per ton. Above the stope a sill of granite has been forced between the folia of the schist, which here has a dip of 30° N.E., and part of the sill has been taken out for ore. Where the granite is ore bearing it is soft, the biotite is bleached, and the feldspars sericitized. Masess of granite have been mined in the second and third levels, which are probably part of the same body that was mined in the first level. The workings on the fourth level were filled with débris and could not be entered, but a small square-set stope is reported to have been taken out of granite. Near the top, on the northwest side of the hill, several other faults, approximately parallel in strike to the northwest limb of the Jupiter fault but with different dips, have been followed by the workings. Two other fault zones have also been worked on the southeast side. One, which is called the K. P. fault, from the

*Abstract from Bull. 430-A, U. S. Geol. Surv., 1909.

name of a stope along it, is about 300 ft. southwest from the Jupiter fault. It strikes northwest and dips at various angles. Near its junction on the northwest with a large shattered granite mass the dip is 30° N. E. Toward the southeast the dip steepens nearly to 60°. Some ore has been taken out along its course, but it has not been a large producer. About 75 ft. farther southwest is another fault called the Oriental. In strike it is nearly parallel to the Jupiter fault south of the gulch, and the dip is in the same direction. It has been followed for over 1000 ft., and at the southern end it is very irregular in direction, is split up, and shows signs of either changing its direction or dissipating into a number of small faults. A stull-stope 5 to 18 ft. high, reaching nearly to the surface, has been taken out along it.

Stockworks in Granite.—The second type of ore deposit in the Yellow Aster mine is made up of large bodies of granite, which are shattered and impregnated with gold along narrow cracks forming complicated reticulations or stockworks. The biotite of the granite has been bleached and the feldspar decayed. Gold is not found in paying quantity where the granite is not largely decomposed, but on the other hand there is no assurance of gold where the granite is decayed. In the lower levels, where oxidation is not so far advanced, there is considerable arsenopyrite in the rock. On the Rand level two large square-set stopes, the 'East sets' and the 'West sets,' have been taken out from stockworks. They lie about 500 ft. southwest (into the hill) from the point where the Jupiter fault crosses the gulch and almost form a chord to the crescentic fault. The East sets have a length of 265 ft. and a maximum width of 95 ft. and 50 or 60 ft. high. They have a strike between N. 75° W. and N. 80° W. The sets have largely been filled with waste, so that the upper sets are not accessible, and the mine maps show no cross sections. The West sets are 340 ft. long, have a maximum width of 50 ft., and reach upward to the bottom of the glory hole, 115 ft., and strike nearly northwest. The two stopes are in the same mass of granite, 150 ft. of which lies between them. It is said to be a low-grade ore. Below the Rand level large square-set stopes which extend to the first level have been taken out in the granite mass.

Strong faults with a stiff clay gouge bound the northeast side of the granite in the West sets and dip 45 to 50° N.E. In places the gouge is damp, possibly from leakage of water in the open-cut above. The Nero stope, which extends from the Rand level to the first level, follows the fault. It is not known what the value of the ore taken from the stopes in the granite has been, but it is believed to have been from $4 to $5 per ton in the East and West sets and probably about the same in the other stopes. There have been places where the value was considerably greater, but the figures given are probably near the average.

Fissure Veins.—Lying within the curve of the crescent-shaped Jupiter vein, between it and the granite, are two nearly vertical veins known as the Jake Price and the Rand Vertical veins, striking about northwest. On the 100-ft. level they are 65 to 110 ft. apart, the Jake Price being the nearer to the Jupiter fault. On the Rand level there is little to be seen of the Jake Price vein. Above the first level the two veins lean toward each other so that they are only a few feet apart at the Rand level. The Rand Vertical vein runs above the Rand level and joins with the Jupiter fault. At the junction and above it some rich ore has been taken out. The veins have been stoped continuously from a point below the 200-ft. level to the Rand level, and the Rand Vertical for perhaps 50 ft. above to the Jupiter fault. Both of the veins are in narrow shear zones that lie mostly in granite dikes but also cut the schist. The cracks of the zone are considerably iron-stained, but no other mineralization is visible. There is some

Johannesburg, Kern County, California.

bleaching of biotite through several feet of granite along the vein. Parts of the veins have been rich, yielding ore worth over $100 per ton. The Rand Vertical, below the second level, follows a granite dike and has been followed downward by a shaft for more than 150 ft. In many places the dike is only 3 to 4 ft. thick, and at the depth mentioned it dips into the wall to the north. Several other fissure veins similar to the Rand Vertical and Jake Price are exposed in the glory hole.

Mining.—There are between 12 and 15 miles of drifts, tunnels, and shafts in the Yellow Aster mine, but at present practically all the work is being done in the glory hole, and it is the intention to work the mine hereafter entirely by open-cut. The grade of the ore mined is thus reduced, but it is estimated that it can be kept high enough to yield a profit. A tremendous amount of overburden must be removed and much nearly barren material must be milled, but the cost of mining is low.

Other Mines.—Across the valley, northeast from the Yellow Aster mine, are four mines opened upon a fault that strikes northwest and dips 30 to 75° N.E., with many local variations in dip and strike. A diabase dike, from 15 to 40 ft. wide and a little more than a mile and a half long, runs along the course followed by the fault. In some places it is cut by the fault; in others sills from the main dike run along the fault, and the fault shows that movement has taken place along it since the intrusion. The diabase both cuts and is cut by granite porphyry dikes. It is, therefore, contemporaneous with the porphyritic intrusions and with the faulting, having been later than the first breaking of the fault, but

movement in the fault continued after the intrusion of the diabase. The gold deposits of the mines along this fault belong to the fault-lode type. From northwest to southeast mines along the fault are the Little Butte, credited with an output of $35,000, and now unworked; the Kenyon, or '400'; the Butte Wedge, which, in conjunction with the Kenyon, is reported to have produced $500,000; and the Butte, reported to have produced $525,000. Still southwest of the Butte are the Philadelphia Wedge, Jenny Lind fraction, Hector, and Magpie claims. Some ore is said to have been taken from each of these. There is more quartz in the fault matter in these mines than in the Yellow Aster. The distribution of value is exceedingly erratic and the ore is ordinarily in lenses, which may be either rich or poor, large or small. One lens in the Kenyon was 10 ft. thick and averaged $100 to the ton. It was 40 to 50 ft. long. Other lenses are only a few inches thick and a few feet long. The material on either side, so far as can be told by the eye, may be precisely similar but almost or totally valueless. North of Randsburg on the claim known as the American, the principal workings are on a fault striking N. 20 to 30° W. and dipping 40° E. A claim farther north and others in the vicinity are in comparatively flat ground known as the Pumpkin Patch and are all along similar faults. They have produced a few thousand dollars in gold, but none are now being worked, as the paying ore near the surface was soon taken out. At Johannesburg the Phoenix (formerly the Val Verde) and the Pinmore are working upon fault lodes similar to those of the Butte and Yellow Aster. In the Phoenix both diabase and granite-porphyry dikes have been intruded along the fault. In the Pinmore the faulting is complicated. The mine is partly caved, and there are no maps, so that the system of faulting was not solved. Southeast and south of Randsburg the Rattlesnake, Gold Bug, Baltic, Blackhawk, Gold Coin, California, Nancy Hanks, Big Horse, Josephine T. G., Golden Link, Hard Cash, and some others are situated on similar faults and have produced more or less gold. In the Baltic ores said to carry about $7 per ton were taken out in one stope, which was 24 ft. high and 60 to 70 ft. broad. Scheelite is said to show in most of the pannings from the mine, and a ton was taken out in one place. It is also found in other claims. The lode on the Buckboard claim 2½ miles in a direct line southwest of Randsburg, may be classed with the fault-lode type of deposits, though it shows characteristics of the fissure-vein type. The deposit is along a fault with a dip varying from nearly flat to 35° N. 40° E. The fault is slickened in places. A fine-grained light-colored dike, with no porphyritic crystals, follows the fault so far as exposed on the upper side of the vein matter. The dike, though somewhat broken, is not much crushed. In places it is 4 ft. thick and at other places pinches out. A small, more basic dike shows in a few places. The vein matter is quartz, and apparently replaces the schist crushed by the fault. The quartz is everywhere impure and porous, but in general is comparatively white. At one place about 200 ft. down the incline from the mouth of the shaft the vein is 15 ft. thick. In other places it pinches or degenerates into mere stringers in the schists. There are many small pseudomorphs of hematite after pyrite or arsenopyrite. A thousand tons of ore from the Buckboard was hauled to Johannesburg for milling tests and is reported to have run $6 per ton.

Other Stockworks.—The only gold deposits of the stockwork type in the quadrangle besides those of the Yellow Aster mine are on claims adjoining the Yellow Aster properties on the northwest. So far little or no ore has been taken from them. The granite is said to carry $4 or $5 per ton. To pay, it would have to be worked on a large scale; and as water would have to be obtained—a very expensive undertaking.

Other Deposits of the Fissure Type.—The mines of the quadrangle which work fissure veins are in what is known as the Stringer district, along the southeastern side of the Rand mountains, from 1½ miles south to 4½ miles southwest of Randsburg. They are comparatively small mines, working veins which, though generally narrow, are in places rich. The district receives its name from the narrowness of the veins. The vein upon which the Sunshine and La Crosse mines are situated is the best known. The Sunshine is on the south side of a shallow valley and the La Crosse is a few hundred feet west, on a small hill. The vein strikes N. 80° E. and is said to dip 5 ft. south of the vertical in a depth of 450 ft. The country rock is gray mica-albite schist, which strikes N. 10° E. and dips 70 to 80° E. The vein is in places 8 or 10 in. thick, but is ordinarily less. From 2 to 6 in. is the average thickness. Quartz crystals have grown from the sides and the combs have grown together and interlocked until the vein is nearly solid. In only a few places are there vugs in which the quartz crystals retain their individuality. Gold is visible in the vein in many places. The largest aggregates of gold seen in the quadrangle were taken from the 350-ft. level of the Sunshine mine. Two pieces, thought to weigh about 3 oz. each, were made up of small crystals of gold. The vein is crossed by a number of faults which offset it a short distance and by others which, as far as prospecting at that time showed, cut it off completely at both ends. Other veins of the same type occur in the Stringer district on the Winnie, Napoleon, Santa Ana, Pearl Wedge, Merced, Royal, Corona, Sidney, Yucca Tree, Bully Boy, Golden Link, and other claims that are not worked. The Napoleon is reported to have yielded nearly $1000 per foot from a shaft 100 ft. deep, but this seems to have been its richest part and it was not being worked when visited. The Winnie was the first of the Stringer claims discovered. At one place the quartz was 2 ft. thick and gave $140 per ton on the plates. This was both the thickest and the richest part of the vein. Where worked in November, 1909, the vein was split into four or five branches, from 1½ to 3 in. thick and spread through 3½ to 4 ft. of schist. The ore here yielded about $50 per ton on the plates. The quartz is said to show a small amount of scheelite upon panning. In the Gold Bug claim the scheelite occurs in small lenses in the gold ores—the scheelite itself not carry-

ing gold—and is not so badly crushed as the gold ore. In the Sidney mine scheelite of a bright buff color occurs in veins with gold, but it was seen only where the vein had been more or less disturbed. Gold occurs in the vein close to the scheelite. In the Corona claim, three miles south of Randsburg, on the 50-ft. level, a lens of quartz 5 in. thick contained about an inch of albite feldspar in the middle. A sample taken from this part of the vein was crushed and panned and gave a prospect of gold, equivalent to $25 per ton.

The veins in the Stringer district are all more or less disturbed by faults. On the Bully Boy, two miles south of Randsburg and three-fourths of a mile west of the Sunshine mine, a vein which was rich at and near the top is cut off 75 ft. below the surface and has not been found again. On the Corona, Sunshine Fraction, and Sidney claims the veins are also badly faulted. The Gold Coin and Stanford claims, three-fourths of a mile east of the Sunshine mine and nearly two miles southeast of Randsburg, have a combination of both fissure veins and fault lodes. Along the fault in silicified crushed material there are lenses of rich ore carrying visible gold. Besides the fault lode there are a number of narrow veins, some of which are little wider than a knife blade, but in places they reach a thickness of 8 in. The veins in some parts carry $120 per ton in gold. The richest parts are said to be where there is most iron oxide.

Outside of the Stringer district, veins on the St. Elmo claim 5½ miles southeast of Randsburg, should also be classed as fissure veins. The veins cut granite. The St. Elmo dips 78° N. 60° W., and is 4 to 10 in. thick. It is reported that $45,000 was taken from a small open-cut between 10 and 15 ft. deep. Several shafts were sunk in search of other ore, and some stoping done on the veins, but apparently no large bodies of ore were found, as the mine has not been operated for three years or more. The ore is quartz carrying visible gold and is said to have been rich. Scheelite is said to have been found in pannings of the crushed ore, but none was found in a specimen tested by the writer. The mine is in comparatively level ground and no other paying gold ore has been taken out nearer than the Blackhawk mine, three miles northwest, though there is a narrow, short gold-bearing vein a mile north by west on the Murphy claim. This property is situated in the Atolia scheelite belt, and the vein is practically parallel to the scheelite veins. It strikes east-west and is vertical. A shaft 20 ft. deep has been dug on it, and enough gold was taken out to pay for the labor.

Summary and Theory of Origin of the Gold.—The rocks of the Randsburg quadrangle may be summed up as follows: granites of different textures and compositions, covering about five-tenths of the quadrangle, occur in the south and north; mica-albite and chlorite-albite schists, of unknown age and believed to be of sedimentary origin, with some interbedded quartzite and limestone, occupy over one-tenth of the area and form the Rand mountains; somewhat metamorphosed sediments, probably of Paleozoic age, including many beds of limestone, occupy less than one-tenth of the quadrangle; lavas, probably of Tertiary age, composed of rhyolite, andesites, basalts, and others, occupy more than two-tenths of the area; sand and other unconsolidated fragmental coverings hide somewhat less than one-tenth of the rocks of the quadrangle.

A large crescent-shaped granitic intrusion, four miles long and one-half mile wide, cuts the schists of the Rand mountains on the south side of Randsburg. Near this, and probably connected with it, are many porphyry dikes of widely varying composition.

The rocks are extensively faulted, and the faults near the Rand mountains are believed to have been largely caused by stresses accompanying the intrusion of the granite. Some granite porphyry dikes were intruded along the faults, after the fault-lines were established, as there is much crushed material alongside the dikes. There has been some movement in the fault since the intrusion of the dikes, and they have been more or less shattered by it. In other places the strike of the porphyries is across that of the faults, but nowhere are they known to cross the faults without displacement. Most of the faults and fractures due to the intrusion of the granite strike within the northwest and southeast quadrants. The principal gold deposits lie in the schist area, rather closely connected with the granite. They may be divided into three principal groups: (1) fault lodes, deposits along faults in crushed schist and granite; (2) stockworks in granite; (3) fissure veins, with more or less quartz. All three types occur in the Yellow Aster mine. The mines north and east of Randsburg are of the fault-lode type.

Although stockworks form some of the most important deposits in the Yellow Aster mine, no other mine has produced much ore from them. In the Stringer district, lying south and southwest of Randsburg, the working mines are all upon narrow fissure veins which have a maximum width of 2 ft. and a maximum length of 500 ft. All are badly cut by faults. The ores in the fault-lodes and stockworks are greatly oxidized where productive, and all shafts are comparatively shallow.

In mines there always should be certain rules respecting the use of explosives and the foreman should be charged with the duty of seeing that these are strictly enforced to the letter. The cartridges should always be kept in safe places removed from shocks of all kinds and especially from the detonators; they should not be fitted with the detonators except directly on the spot where they are to be used and only just the number required for immediate use should have the detonator attached, for it is always dangerous to remove the detonator from a cartridge. Where this has to be done, no precaution should be neglected and the cartridges thus removed should be stored in a safe place. If a cartridge with the detonator attached has become frozen the detonator should only be removed after the cartridge has been thawed, and in this last operation altogether special precautions should be taken.

Surface Indications of Ore-Shoots in Depth

By William H. Storms

The following is written in the hope that others who may have observed the phenomena here described, and have given the conditions some study, may throw additional light on the subject. I have endeavored to express my ideas as plainly as possible, for it is not always easy to explain clearly to another what may seem a very simple proposition. The theories advanced are not altogether new, and many engineers and geologists doubtless have observed some of the conditions hereinafter referred to. The adoption of arbitrary laws or rules to govern the judgment in the valuation of mines and mineral deposits, particularly those that are undeveloped, is dangerous and is likely to lead one into serious error. Yet, when after years of observation in many regions, widely separated, it is noticed that certain topographical conditions are almost invariably found to accompany the occurrence of rich ore deposits, it seems proper at least to submit these observations to the criticism of others who have had similar or even better opportunities for observing the facts, and in this way, by the collation of the evidence submitted by numerous observers to, perhaps, learn whether or not there are any rules that may be applied to undeveloped mines which would be of value in guiding those in charge of mining operations at new properties.

The observations here set forth are particularly the result of a careful study of conditions on the Mother Lode of California, but I have, with equal care, applied them to mines elsewhere in South Dakota, Colorado, Arizona, Nevada, Mexico, and Central America, where I have had opportunity to personally study conditions, and I must say I have not as yet found the place where the more important 'rules,' if this term may be permitted, will not apply.

My observations, particularly on the Mother Lode of California, for over 100 miles, have led me to the following conclusions as to the superficial or topographical conditions which may be considered indicators of the occurrence of ore-shoots beneath the surface:

1. A smooth hillside, or nearly level, or plane surface, without gulches or gullies, or other depressions **crossing the strike** of the Lode is essential.

2. Gulches or natural depressions crossing the strike of the Lode, or vein, are the physical expression of disturbance beneath the surface, and it is rarely, if ever, that an ore-shoot will be found to extend from solid unbroken ground beyond such surface evidence of disturbance. It is important to notice the relation of vein outcrop to these gulches, breaks, or depressions, particularly where there is more than one vein. For instance, where the belt is wide, including several veins, the irregularities of the surface on the foot-wall side of the belt will be found to have a direct influence on the veins in the immediate vicinity (on or near the foot-wall), while having no evident effect on a vein on the opposite side of the belt, near or at the hanging wall. This rule, of course, applies to the occurrence of depressions on the hanging-wall side of the belt, the influence of which is not noticeable on the foot-wall side. However, gulches or depressions which in their course extend entirely across the belt will be found to have a direct influence on every vein occurring in the belt in its vicinity. These cross-canyons, or gulches, are particularly pronounced in their effect, no ore-shoots passing through them without much disturbance, and usually a complete discontinuance of pay-ore. Occasionally such gulches mark a fault-line, particularly if the gulch has steep sides—broad flat depressions being more likely to mark a flexure in the rocks, and not necessarily an abrupt fracture and displacement. Should the fault or flexure have a dip, one way or another, from the vertical, the ore-shoot may take a similar trend or pitch along the fissure in which it occurs, but eventually the shoot will be found to terminate when the region of disturbance has been reached, whether it be vertically beneath the break, appearing on the surface or in depth at some distance to one side of it.

3. A gouge at the surface is desirable, whether quartz be present or not, as the gouge is indicative of a line of weakness and of movement which has taken place, usually subsequent to the formation of the vein. A vein of payable ore may exist below, however, when there is neither vein nor gouge at the surface, nor any other evidence to indicate such occurrence of ore beneath. The South Spring Hill mine near Amador City, supplies an example of this somewhat unusual condition. There the apex of a vein was discovered at contact of black clay slate and amphibolite schist at a depth of 500 feet, at which level the vein began as a mere wedge of quartz, but which widened rapidly with depth. This shoot produced $1,500,000. The surface topographical conditions were not unfavorable to the occurrence of an orebody, notwithstanding that there was no evidence of one to be seen.

4. The occurrence of gouge at the surface is by no means an indication to be relied upon of the occurrence of a payable ore-shoot below. Experience in a number of places has demonstrated this.

5. Often, and it may be said generally, a seepage of water may be found at some place along the surface outcrop of the fissure containing ore. This, like the gouge, cannot be implicitly relied upon as positive evidence of the occurrence of ore beneath the surface, for water will issue with the same facility from a barren fissure, from cracks, from zones of fracture, and from the contact of a dike with the enclosing rocks or from the dike itself, as from a fissure containing the richest ore. It is well to remember, nevertheless, that every pay-shoot is, or has been, accompanied by water, which came into it from below or from the walls, following the fissure, and in many places confined to the channel by selvages of clay or gouge. If the water rises to the surface, it will seep or flow out at the lowest places along the outcrop, at which points these outlets are recognized as seepages or springs. In many places

the vein-water fails to reach the surface, or perhaps it flows only during the rainy season, and for a short time thereafter. It may be concluded, then, that a spring or seepage of water is the evidence of a vein, a fissure, zone of fracture, crack, or dike, or even a contact of two rocks, beneath the surface, but it cannot be accepted as *prima facie* evidence of a pay-shoot beneath. On the other hand, pay-shoots, or veins containing them, do not always indicate their proximity by the issue of springs of water at the surface, for some very valuable ore-shoots are known not to have been accompanied by such water seepages or springs, at least not within historic period.

6. Where a series of branching or nearly parallel veins occur it is seldom that a pay-shoot will be found immediately back of another on a parallel fissure—they generally occur *en echelon*. While the former principle, as it seems, may usually be depended upon with much assurance, the latter is by no means invariable. In other words, a pay-shoot in one vein is not certain, by any means, to be followed closely by another in a neighboring parallel vein.

7. There is no means of determining, without actual development, at what distance a pay-shoot will be succeeded by another in the same vein, or in an adjacent parallel vein, nor at what depth a pay-shoot will occur.

8. Mineralization along the surface, as indicated by the extensive decomposition of the country rock for a considerable distance on either side of a fissure is an excellent sign of the existence of strong veins or bodies of ore below. There are exceptions to even this rule, but such mines as those of the Utica group at Angels; the Kennedy, near Jackson; the Keystone, at Amador City; and the Bunker Hill, near the Keystone, are a few of the many excellent examples of extensive mineralization at the surface where valuable mines have been developed. It is important, however, to recognize the fact that the Eureka Consolidated mine, at Sutter Creek, and a few other noted mines, possess this characteristic in surprisingly moderate degree.

9. A quartz outcrop is not essential to the existence of a valuable mine, nor is a quartz cropping a reliable indication of a body of pay-ore. Some of the poorest mines on the Mother Lode of California have huge white outcrops of barren quartz, and some of the best mines on the Lode have little or no outcrops at all.

10. There is no means by which the value of ore beneath the surface, as yet undeveloped, may be even approximately determined, regardless of all signs at the surface, favorable or otherwise. Only actual development can make this condition known.

11. Strike and dip in veins is generally considered as unimportant, but on the Mother Lode, and to a great extent elsewhere, the ore-shoots are larger and often richer where the veins flatten in dip, being narrower and poorer in the steeper portions. To this, like most of the other conditions, there are some exceptions, but the greater number of places conform to the conditions described, not only on the Mother Lode, but generally elsewhere.

In a general way the conditions above described are found to apply throughout the length of the Mother Lode, and to many other districts as well. Some of the more noted instances are the Princeton mine in Mariposa county; the Jumper group, at Stent; App group, at Quartz; the Rawhide mine; the Bonanza mine, at Sonora; the Soulsby and the Confidence mines in Tuolumne county; the mines of Carson hill; the Utica group, at Angels; and the Sheep Ranch mine in Calaveras county; the Zeila and the Kennedy-Argonaut group; South Eureka, Central Eureka, Eureka Consolidated, Keystone, Bunker Hill, and Plymouth Consolidated mines in Amador county. All of the mines named are famous and have produced many millions of dollars.

Other noted examples are the Yellow Aster, in Kern county, California; the Homestake group, South Dakota; all the mines of the Comstock Lode, Virginia City, Nevada; and in this connection it may be said that John A. Church and George F. Becker each have called attention to the relation of ore deposits to surface topography of that famous Lode; the Camp Bird, Revenue, Atlas, Tomboy, Smuggler-Union, and Liberty Bell mines in the San Juan region of Colorado; the Independence, Portland, Mary McKinney, El Paso, and a score of other mines in Cripple Creek district, each illustrates the more important principles above described.

These are mostly gold mines, but the rules apply with equal force to mines of silver, copper, and lead, such as the Broken Hill, New South Wales; Mount Morgan, Queensland, Australia; the Bunker Hill & Sullivan, in the Coeur d'Alene, Idaho; Dos Pilares, near Nacozari, Mexico; and to the original mine of the Espirito Santo, near Cana, in the Darien, South America, and also the Rosario in Honduras. These, and many others, answer to practically every requirement of the 'rules,' as expressed in the foregoing.

That the theories will apply with equal force to bedded deposits, such as those of Leadville, I am not sure, though I know that to some extent they are not at variance with conditions in that district, nor with the bedded deposits of the Black Hills of South Dakota.

The most important lesson to be learned, it seems to me, is from the negative side. While it may be impossible to tell how good a mine may prove to be with ideal superficial conditions, it seems a safe proposition to 'steer clear' of mines situated in gulches crossing the strike of the vein, or in a country cut by a succession of short ravines. There are few good mines within the range of my experience, situated in such places as these, though there may be important exceptions, of which I have no knowledge.

This has been written, as I said in the beginning, in the hope of interesting others to the extent of giving to those engaged in the industry the benefit of their observation along these lines

Phosphor-bronze wire is employed in the manufacture of screens that are to be subjected to contact with acid which corrodes brass and steel wire screens.

A Modification of Pachuca-Tank Practice

By Amos J. Yager

Having seen various articles in your journal on the subjects of pulp agitation and zinc-dust feed in connection with the cyanidation of silver ores, and believing that there are some interesting developments on these lines, I give you the following data: In this plant the usual custom in grinding is followed, namely, preliminary crushing in rock-breaker and stamps (20), then tube-mills, one 4 ft. 6 in. by 16-ft. Allis-Chalmers mill and one 8-ft. Hardinge conical mill. Classification is accomplished with Dorr classifiers and thickeners, followed by pneumatic agitation in Pachuca tanks, 13 by 55 ft., filtering on two Oliver continuous slime filters, 11 ft. 6 in. by 12 ft., and precipitation with zinc dust in Merrill press. The crushing, classsification, and settling of the ores here present no unusual features, but in the matter of agitation and precipitation I think practice here has developed some new points which will be of interest to the profession.

Device for Handling Zinc Dust.

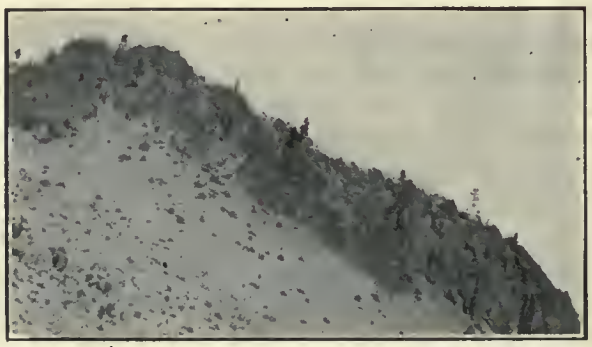
Agitation.—While Pachuca tanks are recognized as a simple, cheap, and, to a certain extent, efficient means for the agitation and aeration of pulp, they fall considerably short of what might be desired in the matter of aeration, most of the air escaping in large bubbles at the top of the column pipe with no benefit to the pulp. Observing this, efforts were directed to overcome the defect by cutting off the column pipes as follows: Out of three Pachuca tanks the column pipe in one was cut off at one-quarter distance from the top and raised, all the air thereby being brought into more general contact with the pulp from a point one-quarter distant from the top of the tank, and a reduction in the value of tailing became immediately apparent. The column pipe in No. 2 Pachuca was then cut in two in the middle and the upper half raised, resulting in still better aeration and a still further reduction in value of tailing. Pachuca No. 3 was left with column pipe full length. With the tanks in this condition several charges were run in each, the average tailing from No. 1 being 0.05 oz. per ton lower than from No. 3 and those from No. 2 being 0.16 oz. lower than No. 1, or 0.21 oz. lower than No. 3, the unaltered tank. The theory being thus apparently confirmed, a second series of five charges per tank was run with the column pipes as above described (No. 1 one-quarter off, No. 2 one-half off, No. 3 full length), resulting in average tailing as follows: from No. 1, 1.90 oz. per ton, from No. 2, 1.84 oz. per ton, and from No. 3, 2.09 oz. per ton. In all cases after 18 hours agitation. Subsequently all column pipes were cut in the middle and the upper portions raised, resulting in a corresponding reduction in the value of tailing. The cutting of the pipes has the further advantage that it is possible to commence the agitation of a tank when it is only half charged; also agitation is more easily started when for any reason it has been necessary to temporarily cut off the air; and agitation from the middle of the tank tends to prevent the settling of sand. The maximum power required for agitating a 100-ton charge of 1½ solution to 1 of pulp is 4 hp. Leaving the Pachucas the pulp goes direct to the Oliver filters, which easily handle 200 tons per day between them in a satisfactory manner, considerably exceeding the rated capacity. The solution is then precipitated by the use of zinc dust in a Merrill press, to which it is fed by gravity flow.

Precipitation.—The zinc was originally fed with the Merrill zinc-dust feeder, consisting of a 12-in. belt conveyor, 10 ft. long, operated by floats, and discharging into a cone, where emulsion was supposed to be made by the use of air. Owing to the irregularity of the operation of the belt and the uneven distribution of zinc dust on it, and the fact that the cone failed to make a perfect emulsion, a large percentage of the zinc settling and caking on the sides of the cone, the whole apparatus was abandoned, and the following equipment made, which is now in use. This equipment consists of a receiver having a diamond-shaped cross section (as described by J. S. Colbath in *The Engineering and Mining Journal* of February 26, 1910), this taking the solution direct from the press, measuring the flow, as indicated by a register attached to a tripper, and also regulating the quantity of zinc required. The receiver operates the tripper above mentioned, which makes an electric contact each time the receiver dumps. The contact current passing through a coil-magnet operates the zinc-feeder, which has a ratchet attachment for the purpose, and which is situated at the clarifying tanks, 400 ft. distant from the press. The feeder is operated on the Challenge principle, the feed of zinc being further regulated by a gate on the hopper. The zinc dust is discharged into a launder and flushed direct into a miniature tube-mill, 4 by 14 in., charged with pebbles and run at a speed of 60 r.p.m. This makes a perfect emulsion, which we find indispensable; has materially reduced our consumption of zinc, and resulted in producing a high-grade precipitate, running 80% silver, whereas formerly our precipitate ran only from 35 to 50%. This scheme has been in operation several months with excellent results. It is automatic, and the cost of operation is practically nil, the tube-mill being operated with a ¼-hp. motor.

An Interesting Stockwork

By I. F. Laucks

Several miles from Wenatchee, Washington, in a fruit raising country, is a rather remarkable gold property. The mill belonging to the property stands in the midst of a fine orchard. This same orchard is planted on the extension of the formation which is being mined. Probably few mines or mills are situated in such pleasant surroundings. The property is in Quilchuck canyon, on the west side of the Columbia river. The gold-bearing formation is a large dike, cutting across the canyon, several hundred feet wide, and said to be traceable for fifteen miles in length. Outlying portions in one place give a total width of over a thousand feet. At the point where it is being mined it stands above the surrounding country from 300 to 500 ft. The dike is a light-colored, acid rock, probably rhyolite. Its weathering renders exact identification difficult. On its flanks are sedimentaries, sandstones and shales, which are probably of Tertiary age. About a mile from the



Outcrop of the Orebody.

dike, up the canyon, is a seam of lignite which was mined some time ago. The dike has been much faulted and fractured, the faults being of small throw, several feet, for the most part. Quartz veins and stringers of all sizes, from a fraction of an inch to several feet in width, running in all directions, have filled an older set of fractures. These have again been faulted and fractured, and in some cases a new set of veins has been formed. Most of the quartz is rusty, and so frequent are the veins and stringers that the general color of the dike rock over large areas is red, stained by the interspersed quartz. Some of the stringers are high in gold, and all of them seem to contain gold. Pieces of dike rock, without any visible quartz, also contain gold in profitable amount. This combination of dike rock, and the innumerable reticulated quartz stringers, all containing gold in varying amounts, constitutes the ore of the property. There are several quartz veins large enough and of value enough to constitute a good prospect in themselves, but the plan is to work the dike as a whole. Conditions are favorable for cheap mining, as practically all there is to be done is to shoot the rock down and run it to the mill. The mill feed so far has all come from the loose rock around the sides of the dike, of which there is an enormous amount.

The mill at present consists of six Nissen 1800-lb. stamps. They fall 106 times per minute, with a 7-in. drop. Crushing through a 50-mesh slotted steel screen, 6 to 7 tons per 24 hours, and through 30-mesh, their capacity is estimated at 12 to 15 tons. The height of discharge is only 2 to 3 inches. Cams, shoes, and dies are of chrome steel. The stamps were designed for large capacity, and are used as crushers only, no inside amalgamation being attempted. The pulp is run over plates and canvas tables at present. The gold is very fine and fine crushing is necessary to a successful saving. The illustration gives some idea of the amount of weathering and fracturing which has taken place. The highest point here shown is about 500 ft. above the millsite.

THE PREMIER DIAMOND MINE

According to the *Rand Daily Mail*, the Premier diamond mine is situated on the farm Elandsfontein No. 85, approximately 25 miles east of Pretoria, near the top of the watershed dividing the Elands and Pienaars rivers, and was discovered by T. M. Cullinan, the present chairman of the company, in November, 1902. The pipe is bounded by hills of an average height of 100 ft., principally of a sandstone and quartzite formation, and these form the rim rock of the pipe. The area of the mine is equal to 3570 claims of 900 Cape square feet each. In English measurement this represents 3,561,300 sq. ft., or say 78 acres. The mine is being worked in levels or terraces, 50 ft. in depth, and in view of the area of the pipe, and the hard nature of the rim rock, it will be possible to continue the open workings to a depth of 1200 or 1500 ft., which will represent approximately 500,000,000 loads of 16 cu. ft., or say 40 years' work calculated on an output of 12,000,000 loads per annum. Nine bore-holes have been put down within the pipe area to depths varying from 300 to 1000 ft., and the diamonds extracted from the core obtained show a favorable yield throughout. It being the policy of the company to start operations without delay, two temporary washing gears were erected, comprising respectively, three and eight pans each. Work was commenced with the former in April 1903, and with the latter in January 1904. In view of the facilities afforded for working on a large scale, however, arrangements were subsequently made for the erection of an up-to-date direct double treatment plant capable of washing 20,000 loads of 16 cu. ft. per day of 24 hours, and work with this gear, which is the largest of its kind in the world, was commenced in November 1905. Up to the end of May 1908, the No. 1, 2, and 3 gears had treated 16,696,588 loads, from which 5,725,426½ carats of diamonds were recovered, equal to 1 ton, 3 cwt., 1 st. Among many other large stones, the mine has yielded the largest known diamond in the world. This stone is of the best quality, and weighs 3025¾ carats. It is now numbered among the Crown gems of King George IV of England.

The stone is a common measure of weight in many countries of Europe. The English Imperial Standard stone is 14 pounds avoirdupois.

The Cost of the Goldfield Mining Boom

By Augustus Locke

Eight years ago the gleaming desert in which Goldfield is situated was uninhabited, inaccessible, and little known. The sudden upbuilding within this desert of a large mining community, together with a mature and great mining industry, has involved a most unusual application of human energies. In general, the psychology of mining is peculiar. This, I suppose, is due to the fact that, more than in any other industry, there is room in mining for the imagination. The fortunes of mining undergo sudden and wide variations. The powers of the best developed mine are, to some degree, hidden: the results of next month's and of next year's work are, to some degree, unknown.

The City of Goldfield, Nevada.

As a result of this uncertainty, always present, the unskillful see the industry in caricature, and an exaggerated hope of brilliant success fixes their thoughts. Such views, developed to an extreme degree, originally pervaded Goldfield. In its truest sense, the camp underwent a mining excitement. Indeed, the peculiar story of the camp is intimately woven with the story of this excitement. There were a multitude of difficulties in the way which would have turned aside or long delayed other enterprises; but here they were overcome easily and promptly by the impact of the powerful enthusiasm which accompanied the boom.

Effective as it surely was, this enthusiasm was not less illogical than it was powerful. It constituted a huge and awkward force which denied the use of reason. In its blind activities, it did much good and much harm. To estimate accurately in dollars what gains and what losses it accomplished is impossible. It is, however, possible to investigate the matter qualitatively. I propose to indicate where the gains and losses came, and to arrive at a judgment as to the debits and credits. As preliminary to the understanding of the Goldfield boom, it is necessary to realize that it consisted of two unlike parts. The first of these was the 'maelstrom' within the camp. As has been suggested above, this took the form of tremendous activity; in essence, it consisted largely of a rapid circulation of money. Money passed from hand to hand with unusual speed. It was easy to get and easy to spend. The second part was the external boom—that seductive force which caused grocers in quiet New England villages to send their good money into the maelstrom. In one way this part was similar to the first, for it encouraged easy expenditure; but in another way it was fundamentally dissimilar, for it offered no ready means of winning the expenditure back. I do not, of course, contend that the internal boom was insignificant, or that it was not primarily responsible for the external boom. I wish merely to emphasize the fact that much of the excitement within the camp was a revolution, not a progress. Much of the stir was self-neutralizing. Big gambling gains and losses, rapid changes in ownership of real estate, numerous transfers of mining stock—these, in themselves, signified little; the individual had an excellent chance to win back on Tuesday what he lost on Monday. These facts being taken account of, it is evident that the essential features of the boom may be covered in a consideration of the following: (1) The building of the town of Goldfield; (2) prospecting and developing; (3) sale of mining stocks; (4) moral effect of the boom condition.

In 1907 Goldfield had a population of 20,000 and a yearly ore production of 100,000 tons. In 1910 it

has a population of 5000 and a yearly ore production of 300,000 tons. At the earlier date the construction of the town and the development of the principal orebodies had been completed. The excess of people was therefore not required either for construction or for development. If it be assumed that the population needed varies with the tonnage produced, the actual population was something like twelve times as great as was demanded by the genuine needs of the community. In other words, eleven-twelfths of the people were on hand because of the boom. In reality the camp had from the day of its discovery been, in this meaning of the words, overpopulated. As a result, it was overbuilt. The average number of vacant buildings is about one out of three, enough in certain localities to produce a decidedly deserted appearance. There are, moreover, a considerable number of incompleted buildings. The slump in 1907 left them, with their unclad rafters, to be a permanent evidence that some persons changed their minds. The decrease in the effective selling value of real estate since 1907 is probably 75 per cent. Prices, at that time, were raised greatly above cost, and they are now much below it. The assessors' valuation of real estate in Goldfield a year or so ago was two and one half millions. It is easy from these figures to make a rough estimate of the real estate loss.

Not less certain than the fact that the desert town was overbuilt, is the fact that the region about it was overprospected. A primitive race, making it a matter of religion to dig holes, could scarcely dig more pitfalls in an age than the prospectors of Goldfield dug in five years. There are holes in the tuffs, holes in the loose wash, and holes in the summits of rocky peaks. To the mind of the excitement-stricken prospector, it did not occur that an investigation of the croppings for a distance of 100 ft. down from the apex of a hill would often render as much information as to its value as the sinking of a shaft for a like distance. In 1907, something like 200 shafts produced 100,000 tons of ore. In 1910, about 20 shafts are taking out 300,000, of which amount 5 are taking out 90%. A close calculation of the cost of fruitless prospecting is not possible. An approximation of the probable maximum is, however, sufficient. Very likely the expenditure did not exceed one and one-half million dollars. The total real loss, then, through real estate depreciation and fruitless prospecting was probably between three and four million dollars. These losses were concerned with the internal boom. The losses concerned with the external boom were of a very different sort, and resulted chiefly from purchases of mining stocks. There were about 200 companies promoted in Goldfield. Almost invariably they had a capitalization of 1,000,000 shares. Each company sold, on an average, one-half of its capital stock. The average price realized is unknown; but likely was 30c. The companies which have since had great success are included in this average, but as their original selling price was low, they bring up the average little or none. The money invested, then, in the initial purchase of the mining securities of Goldfield was something like $30,000,000. These figures indicate that the external boom was several times as costly as the internal boom. So far the losses have been expressed in money. An additional and very substantial loss, the injurious moral effect of the boom condition, cannot, of course, be so expressed. The most striking effect of this sort was high-grading. Indeed, high-grading was not less a cause than an effect. Moreover, it was an effect not only of the boom condition, but of other conditions as well, chief among which was the richness of the ore. Yet the peculiar state of mind which accompanied the boom must be regarded as an essential condition.

The Beginning of the Goldfield Consolidated.

Not over three and one-half years ago the high-grader in Goldfield was a 'perfectly good' and respected citizen. He who refused to high-grade was over nice and scrupulous, and many a man who would scorn to steal money, stole ore. Much astonishment has been expressed that such a condition should have existed. In reality its explanation is simple. The ultimate cause of the condition was the unusual excitement accompanying the hope of extreme success. This excitement was dominant. It eclipsed usual ideas and unsettled customary morality. Goldfield got into the habit of high-grading during the days of leasing. Good miners were then not easy to get unless they were given the opportunity to high-grade. When a lease was fast expiring, it paid better to let the miner who was taking out $200 worth of ore, have $20 of it for himself, than to take out no ore at all. So high-grading was for a time actually countenanced by the owners of the ore. For the average man, the criterion of

morality is custom. What is usual, and what the neighbors approve, is right. In Goldfield, because of the peculiar and general mental attitude, nearly everyone approved. Moreover, as Goldfield was isolated, the influence of outside opinion operated slowly. In a populous locality, the average of morality is maintained by the diffusion of ideas. But ideas diffuse very slowly over two or three hundred miles of desert. These are the reasons why high-grading became extensive, and why it was not in bad repute. There is another bad moral effect, less conspicuous, but not less important. Goldfield has seen the making of sudden fortunes; it has had the taste of extreme hope. Not one man from each thousand is destined to have great financial success. Yet 900 out of 1000 are mentally unfitted by conditions such as existed at Goldfield, for the unromantic labors which by fate they are destined always to pursue. It is difficult to get down to business and take ordinary profits, when for a year you have been dreaming of ten hundred per cent.

The effects which have now been considered are the important losses which resulted from the boom. But there were important gains as well. The mines have produced about $40,000,000. Some of the prospecting, and some of the stock investment was, therefore, very fruitful. But how much of the success was due to the boom? A useful method of arproaching this question is to consider in what way the result would have been less successful had the methods of ordinary business been applied. It is certain that the calm calculations of ordinary business would never so suddenly have established a comfortable town and a great mining industry. It would never have spent money on frenzied prospecting. Nor would it have built houses for a whimsical population which next year might migrate. But for the boom, we might still be buying water by the gallon, and extinguishing fires by primitive methods. Above all, we might still be ignorant of the existence of the Hayes-Monette orebody. In short, the boom benefited the camp by giving it the impulse for sudden development. To the owners of the productive mines, this sudden development was of enormous advantage. It is a notable fact, however, that the people who furnished the money for the boom were not those who reaped the benefit from it. The people who paid $30,000,000 for Goldfield stocks are not the owners of Consolidated. Many declare that we must have booms to develop mines. It would be more correct to say that we must have booms to develop mines at top speed. If this is an argument in favor of booms in mining, it is likewise an argument in favor of booms in other industries. It is entirely certain that, whatever the industry, the visionary attitude is very costly, and that the application of common sense is immeasurably more efficient. For the average citizen booms of any sort are excellent things to keep away from.

Minnesota furnishes from St. Louis county alone about three-fifths of the iron ore produced in the United States; the shipments during 1909 amounting to 29,282,526 tons.

A CIRCUIT TESTER FOR BLASTERS

There has always been much difficulty in detecting unexploded charges, particularly in floor shots, and until recently the blaster has had to depend on his eye to determine whether all of the holes had fired or not. This is at best an unsatisfactory method because, in a number of instances, it has been found that the wires and tamping from the hole were not blown out although the dynamite had exploded perfectly. Although the difficulty of finding a missed hole after the blast has been fired still remains, it is now possible for a blaster, with care, to determine with a great deal of certainty that each of the electric fuzes in a blast are in good condition before the shot is fired. A device known as the du Pont galvanometer or a circuit tester has been invented and placed on the market, which not only indicates whether an electrical circuit is closed or not, but also indicates, within practical limits, the amount of electric resistance in the circuit. A blaster may connect the two leading wires to the galvanometer after the holes are all connected up and the galvanometer will indicate not only whether the circuit is complete or not, but also if there is leakage through bare connections, etc., the number of electric fuses connected in series. For instance, if a blaster has 30 holes, in each of which there is an 8-ft. electric fuse, by referring to the table furnished with the galvanometer, he will see that the total amount of resistance is 33½ ohms. If the needle on the galvanometer now indicates close to that figure, he may be perfectly sure: first, that none of the electric fuses are broken; second, that there is no leakage of current through the bare ends of the connecting wires; and, third, that the leading wires are intact. If a wire of one of the electric fuses has been broken in tamping, the blaster will get no motion of the needle when he connects it to the two leading wires. By going over the bare connections over the holes, it is possible for him in a few minutes to determine which electric fuse has the open circuit. It frequently happens that the leading wires become frayed and the insulation removed in places, and this bare wire may fall over an air or steam pipe or a rail, thereby producing a short circuit through the pipe or rail. When the blaster tests his leading wires on the du Pont galvanometer under these circumstances, it will immediately show a short circuit, and the blaster, knowing that the resistance should be calculated from the number of electric fuses he has connected in series, instantly sees that something is wrong and does not attempt to fire the blast until the wires are lifted clear from the iron. In looking for a break or broken wire in a large floor blast, the instrument can be attached successively to the double lines of bore-holes at the ends so that the line containing the break is quickly found, after which the electric fuses in each bore-hole are gone over separately. It is, of course, not possible to determine positively after a blast has been fired whether the protruding wires from any bore-hole are connected to a live electric fuse or not, as the end wires are usually stripped and crumpled together by the blast when it fires.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Cyanide Problem

The Editor:

Sir—Replying to 'Cyanide Problem' in the issue of August 13, it may be assumed that the premise in this case is "an ore, consisting of a quartz gangue, in which occurs pyrite in abundance, with a relatively small amount of galena, blende, chalcopyrite," gold, and a complex silver-antimony compound; and that the desideratum is, to extract that amount of the several metals or minerals, contained in this ore which will show the greatest profit over cost of operations. The primary conditions to be confronted are that direct amalgamation of the ore, and doubtless, amalgamation at any time, is prohibited by the presence of galena, blende, and the complex silver-antimony compound in the ore; that direct cyanidation of the ore is impracticable, due to the presence of galena, blende, complex silver-antimony compound, and other cyanicides; that any roasting treatment of the ore is prohibitively high, due to cost of fuel and other considerations. Under the conditions imposed we are confined to the process of cyaniding the ore, and as a secondary condition to the use of this method of treatment, we must 'eliminate' the cyanicides, antimony, galena, blende, etc., or at least render them 'innocuous.' To 'eliminate' the elements in the ore detrimental to cyanidation, naturally implies their removal by some mechanical means; and to render them 'innocuous' implies a change from their present state of association to a state not detrimental to the action of the cyanide in dissolving the gold and silver contained in the ore, namely, a chemical change. Now we must decide upon which method or combination of methods should be followed to 'extract that amount of the several metals or minerals contained in the ore, which will show the greatest profit over cost of operations.' As agents for eliminating from the ore, the antimony compound, galena, blende, etc., we may employ classifiers or concentrators. As an agent for rendering the antimony 'innocuous' we may add caustic alkali to the ore; or, we may crush the ore to such a size that a minimum amount of antimony and a maximum amount of gold and silver will be exposed to the action of the cyanide. In regard to the latter proposal I have read that, in Borneo, under the direction of Alfred James, good extraction of gold was obtained from an ore containing considerable antimony and arsenic, by breaking the ore to a size, varying between that of a lemon and a walnut, and treating with a very dilute solution of cyanide. In regard to the second proposal, the alkali, in combining with the antimony, also combines with the oxygen of the air; thus if the alkali-antimony compound be formed in the cyanide solution, the potency of the solution for dissolving would be diminished by the paucity of uncombined oxygen in the solution, as present in air. In regard to the first proposal, there does not appear to be any reason whatsoever that the pyrite, chalcopyrite, blende, galena, antimony-silver compound, and gold should not be removed from the gangue of the ore by concentrating tables, to almost any degree of refinement desired. Now, neglecting for purposes of discussion the last proposal, we must determine the comparative economies between crushing the ore to concentrate, followed by cyaniding the concentrate, and crushing the ore to cyanide, the addition of the alkali preceding cyanidation, or between either of these methods and a combination of them both. Naturally it is not possible here to point out the limit to which any one step in a series of steps composing a method of extraction should be carried or what combination of steps should form a method. But, provided the third proposal be not applicable, from what data we have at hand, it would seem that crushing, followed by concentration, followed by treatment of the tailing with alkali, by agitating the alkali with the tailing by compressed air, followed by cyanidation, would give good results. As must be evident, the above is but a 'speculation' upon the problem given, and is, in fact, an expression of the method of solution proposed for a similar problem, once expected to be confronted, but which finally was not encountered.

LEE FRASER.

Punta Arenas, Costa Rica, September 21.

Standard Mill Construction

The Editor:

Sir—Mill construction after more than a half century of practical experience, it would seem, should have been reduced to almost an exact science, but there are still seen the same divergence of opinions as to what is proper, or improper, construction as there was twenty or more years ago. As a consequence there is no standard of mill design. In the greater or more important features of mill design and construction there is more uniformity of idea than in the lesser details. Most engineers agree that concrete battery foundations, when properly made, are superior to those of wood, but there is still a great difference in the ideas of constructing engineers as to the best form of mortar block, the proper place and the manner of setting the battery posts, and in the method of anchoring the mortars. Anvil blocks are not, as yet, in general favor, and in some mills have even been removed after trial. The position of line shaft is one of the matters in which there is still divergent opinion. Some—perhaps the majority—favor placing the line shaft low down and back of the battery post, others place it in front of the line of mortars and beneath the amalgamating tables, still others preferring to place it on the cam-floor in front of the mortars. This horizontal pull on the cam-shaft seems to me the most undesirable of any of the several positions, notwithstanding the claims of some others to the contrary. In concentration mills is seen the same diversity of arrangement of the various machines. To some extent this is controlled by the needs of treatment due to difference

of the ores, but there is much difference without real cause. Surely there must be some 'best way' to arrange mill machinery, and it would be interesting to know what it is.

MILLMAN.

Nevada City, California, October 15.

Standardization of English

The Editor:

Sir—I note the criticism offered by C. O'Brien in your issue of September 10. He is in error: my use of the word *be* was no Cornish localism but the subjunctive mood as expressive of the conditional. While "familiar with the lingo of the Cousin Jack," I may confess to having learned to speak our language at a great distance from the 'old county.' However, I do appreciate Mr. O'Brien's friendly comment and I am glad to see that he is interested in the subject. The pleasant tilt in which I have recently engaged before the Institution of Mining and Metallurgy here in London has, I believe, caused some of my British friends to "sit up and take notice." It is of no great importance whether my views are accepted or rejected, but it is of first-rate importance that engineers should use the language, and especially technical terms, in a thoughtful way.

T. A. RICKARD.

Hardening and Tempering Drill Steel

The Editor:

Sir—Since the Steel Trust has controlled the supply of drill steel a very inferior article has been sold to the miners. The hardware merchant will tell you that the agents of the Trust simply brand the steel to suit the order, and you have to take what you get and look pleasant. Some time ago I had a quantity of this steel marked 'Canton,' which would check and crack despite the most careful treatment by experienced men. It would crack under the hammer in forging, and if not in the forging it would check in hardening and tempering. We finally learned a method that was fairly successful. It will surely be appreciated by the unfortunates who have to use such steel. It was as follows: Heat the steel to a bright yellow color and hammer into shape before it becomes black. Let cool. To harden, heat to a low red color—as low as possible to harden (you can prove this with a file)—dip vertically in the water to a depth of an inch below the surface, moving it around in circles for about twelve or fifteen seconds; by that time the steel will be chilled and hardened clean through. Now brighten on a soft pine board, sprinkled over with coarse sand or slag from the forge. The heat from the shank of the drill will generally be sufficient to draw the temper to a yellow or copper color, as may be appropriate for the rock to be drilled.

If the heat in the steel itself is not sufficient, it can be held over the fire and brought to the proper degree of heat and color to obtain a good temper. There will be little trouble with the steel if this course is followed closely.

In tempering a pick, if it is allowed to come down to a blue, two or three times repeatedly before the final plunge it becomes very tough and will stand the hardest usage. Try it.

The blacksmith shop should be moderately dark to get the best results. If there is a strong light it is difficult to judge the heat of the steel.

J. A. MACDONALD.

San Francisco, October 14.

Expert Milling

The Editor:

Sir—Not long since I secured a job as amalgamator in a gold mill. I proceeded with my work as I had been taught by a millman who knew the business from the breaker to the tailing-sluice, and who knew it well. After working about the mill as assistant to the millwright for a few weeks I was given a shift on the batteries, for which I had really hired. I was shown a heavy coffee cup containing the quicksilver to be used on my shift. From that cup I took the 'quick' which I fed into the mortars. For some days, or rather nights—I was on night shift—I got along all right, but one night I found the outside plates getting hard. I threw in more 'quick' and dressed the outside plates. After midnight I had to hunt up the quicksilver tank and get more 'quick' as my supply was exhausted. I used nearly four times as much as the boss millman had set out for me. In the morning he noticed that the iron flask had been disturbed and inquired of me about it when I came on shift in the evening. I told him I had found it necessary to feed more silver, and took it from the flask. He told me he had given me all the 'quick' I was expected to use and sent me to the office with a time check. There are no doubt many of your readers who will not believe this, but it is true nevertheless.

BATTERYMAN.

San Francisco, October 13.

Indications of a Mine

The Editor:

Sir—I read in the *Mining and Scientific Press* of October 1 that a man who signs his name 'Missouri' is skeptical that anyone can judge whether a mine will be good or bad before it is developed, or even after it is fully developed. I differ with this person 'from Missouri,' and can 'show him' that it can be done—even long before it is fully developed. A great many claim that mining is all chance. Well, it is to some extent, but while developing a mine there are 'signs' which, if one understand them, tell whether the mine will be good or bad. Of this fact I believe I can convince any reasonable person. 'Missouri' says if a man can tell, he would like to know. There are lots of people who would like to 'know how' if they could get such knowledge for nothing.

R. VINCENT.

Grass Valley, California, October 13.

[The original proposition referred wholly to surface indications and not to developed or partly developed mines. Elsewhere herein will be found a contribution on this interesting and important subject.—EDITOR.]

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Cross-ties to the number of 123,754,000 were purchased by the railroad companies of the United States in 1909 at a cost of $60,321,000. The chief wood used in this work was oak, which constituted approximately 45% of the total. The purchases by steam roads formed about 93%, as compared with 94 in 1908 and 1907.

The first ore from the Missabe range was shipped from the Mountain iron mine over the Duluth, Missabe & Northern railroad in 1892. The total shipments during that year amounted to 4248 tons. Since that time the Mountain iron mine has produced 17,200,000 tons. At the present time there are 92 producing properties on the Missabe range from which during 1909 were extracted 28,174,000 tons.

Tar vapors and other heavy carbon-hydrogen compounds which are the product of distillation of coal under certain treatment burn slowly, and in order to burn them nearly completely they must be kept a comparatively long time within the furnace. To fulfil this condition the furnace must be provided with a large combustion space. Such furnaces, however, are objectionable for obvious reasons. The best remedy probably is to avoid the formation of all these slow-burning volatile compounds by using the principle of the low rate of heating of fresh fuel.

To prevent any air-space in loading a hole for blasting, the cartridge should be split and then pressed carefully to the bottom of the hole with a wooden tamper. The cartridges should thus be pressed against one another, avoiding all shocks and taking good care that no earth or dust shall fall between them; the tamping should be done with sand or ordinary dry earth for the first six inches by pressing lightly with the tamper and then with clay upon which more force may be used in the ramming. Great precaution should also be taken in handling the fuse of electric detonators, for any deterioration of these articles may cause a delay or greater celerity in the explosion, or may make the shot miss fire altogether.

During the session of 1909 the Legislative Assembly of the Province of Quebec enacted some amendments to the Quebec Mining Law which are important. Under the new provisions a miner's certificate must be taken out which is valid from the date of its issue to the first January following. The price of the certificate is $10. Any holder of a miner's certificate may prospect on public lands, whether surveyed or not, or on private lands where the mines are reserved to the Crown. Nevertheless, if such holder of a miner's certificate wishes to prospect on private lands, he must first give good and sufficient security, subject to the Minister's approval, for any damage he may cause the surface owner through his prospecting.

In pouring concrete columns there is always a danger of the formation of pockets, due to large stones being caught between the reinforcing members and between the steel and the forms. Even with the greatest care this cannot be entirely avoided, especially when the columns are long and have spiral reinforcement. Such pockets, if large, may seriously affect the strength of the columns, and it would therefore seem desirable to make a thorough examination of them as soon as the forms are stripped, sounding them for holes beneath the surface, and not being satisfied with a mere superficial inspection.

Manufactures now form, for the first time in the history of our commerce, more than one-half of the total exports of the United States. In the 8 months ended with August, the figures of the Bureau of Statistics of the Department of Commerce and Labor show that out of a total exportation of $1,027,000,000, manufactures amounted to $542,750,000, or 52.8% of the whole. One year ago, out of a total export of $989,000,000 in the 8 months, manufactures contributed $475,000,000, or but 48%; 2 years ago their share was $472,000,000, out of a total of $1,075,000,000, or 44% of the total; 10 years ago, taking the figures for the entire year, manufactures formed 35½%; 20 years ago, 21%; and 30 years ago, 15% of the total exports of domestic merchandise.

Wash out the boiler at least once every month and more often if feed water is bad. Do not allow mud or scale to accumulate in boiler and do not allow oil or grease to enter boiler; these foreign substances may cause over-heating and burning of plates and result in a bag, rupture, or violent explosion. A solution of soda ash or a small quantity of kerosene fed continuously into boiler is often beneficial in preventing or softening scale; when these substances are used, open blow-off cock once or twice a day. If kerosene is used, great care must be exercised to see that it is entirely gotten rid of by allowing a draft to blow through the boiler before bringing a naked light to the boiler or allowing anyone to enter the boiler, as an explosion may ensue or the fumes may overcome the person entering.

Most mechanical stokers are designed so that the coal is fed into the furnace gradually, and therefore the rate of heating is slow. The result is that a comparatively small amount of combustible is driven off as volatile matter, and it consists chiefly of easily burning gases, most of the carbon being left and burnt on the grate as fixed carbon; very small amounts of tarry vapors are distilled, whence the success of most mechanical stokers in burning smoky fuel. As an example, on a well-operated chain-grate stoker, it takes perhaps fifteen to twenty minutes to heat the coal through to the same temperature range of 2400°F., which takes only two or three minutes in the hand-fired furnace. In general, the success of these mechanical stokers lies not in the fact that they consume smoke but that they burn the coal without producing much smoke at all.

Special Correspondence

MELBOURNE, AUSTRALIA

Chillagoe Mines.— Electrolitic Smelting & Refining Co. — Conditions at Broken Hill.—Gold Output.—Mount Lyell.

The Chillagoe company is one of the most important enterprises promoted in Australia in recent years. It was mainly through the reports of A. Stewart, formerly general manager for the Broken Hill Proprietary company, that this company was evolved from the syndicate stage. The reports by Mr. Stewart on the large areas held by the company in North Queensland gave high assays for copper in several of the concessions obtained. The result was that a company with a considerable working capital was formed and £373,000 was raised in debentures for the purpose of constructing railways and building a nest of smelters at Chillagoe. As showing the way in which such enterprises may be begun, the company, although it had not ore developed sufficient to keep the whole of the smelters at work, had to expend under the debenture deed a large sum in building the smelters. Up to the present time the showing developed has not warranted the expense and a great deal of the outlay could have been saved. The mines at Chillagoe, whatever they may have promised at the surface, have generally been disappointments. One of them, the Zillmanton, is now being worked, but it has only about 40,000 tons of ore proved. When the capital of the company is seen to be £451,000 exclusive of the debenture debt of £573,000 on the Chillagoe railway it can be seen that the enterprise has fallen far short of all mining prospects as indicated by its capitalization. Never a dividend has been paid and two reconstructions have been made, and now the company is emerging from a mining venture into an important industrial concern. The backbone of the company is the railway and the possibilities of expansion of the customers' side of the enterprise. So with Chillagoe mines so unsatisfactory the company has recently spent £400,000 in extending its railway system to the Ethridge field. This is one of the most important private enterprises undertaken in Australia, for it means bringing under the control of the company the area of 11,000 square miles full of mineral possibilities. There are many gold-bearing veins in the district containing a certain percentage of refractory ore. In saying this it is not intended to assert that the company has actual possession of the country, but that its railways and works mean that the areas are dominated by it, and that any inflow of population must swell its revenues. The bulk of the debentures and a large proportion of the share capital has been subscribed in London, and it is the sincere wish of every Australian that the development of the Ethridge will bring a return to the company. This could be assured if private enterprise were in no way hampered by socialistic ideas in Australia. As it is the company is so far out of the way of politics that it seems to have a large amount of freedom from all political influences. Besides that, it has not done well so far, and the socialist does not want the State to be burdened by anything that does not pay. He only wants the plums in the dough.

United States refiners are to lose the copper refining contract of the Mount Lyell company, Tasmania, which for many years has gone to Baltimore. The Electrolitic Smelting & Refining Co. at Port Kembla in New South Wales is the successful applicant on this occasion. This concern is the only organization of the kind in Australia, but it has already achieved a name for the purity of its copper. That it should be able to beat all competitors when tendering for the refining work is a fact of no small interest. Australians patriotically are delighted to see these works expand. A considerable amount of additional capital will have to be sunk to provide for the Mount Lyell work, but this money will be at once forthcoming. The real proprietors of the works are the Mount Morgan company, which is now vying with the Mount Lyell company in its output of copper. The bargain is a good one because the Mount Lyell blister copper contains silver, whereas Mount Morgan blister copper does not. So metallurgical operations will be facilitated. Unrest at Broken Hill is still causing anxiety. The trades unions there know that their agreement with the mines for a scale of wages expires at the end of the year, and their desire is to be able to present a case to the Federal Arbitration Court which will induce that body to increase wages. The mines are said to be consolidating their strength, but past jealousies have not altogether vanished. The Broken Hill Proprietary Co.'s mine is still closed and 1900 men consequently are out of employment. The company will not work with lead at the present price. The other companies are believed to be willing to renew the existing wage agreement for five years if the men will consent, but there is a strong agitating element in labor circles which is opposed to any renewal.

The gold yield of Australia shows no signs of improvement though evidences at some of the leading centres are somewhat more cheerful. In Charters Towers, Queensland, some of the deep mines and the outlying districts promise better. In Victoria the alluvial industry is depressed and yields are lower than usual as deep ground is being developed but in Bendigo and in some outlying parts of Ballarat some of the neglected areas are being worked with encouraging results. Any further development in this direction will check the falling goldfield and find employment for out-of-work miners. The Australian gold yield for the past eight months of this year compares with the previous years as follows:

	1908	1909	1910
	Fine oz.	Fine oz.	Fine oz.
January	46,143	40,756	52,057
February	57,732	40,175	42,228
March	58,786	75,489	64,370
April	35,838	49,611	30,622
May	69,682	44,465	49,979
June	61,253	71,209	56,284
July	46,625	42,616	41,218
August	63,726	54,182	45,040
Total	439,785	418,503	381,798

The Mount Lyell mine as a copper producer retains its pre-eminence in Australia. The way in which the ore has maintained its richness in the company's North Lyell mine and has continued in the schist has astounded mining men when the contraction of the shoots at above 750 ft. are remembered. But the 750, 850, and 1000-ft. levels have been veritable store houses of wealth. So the expectation was that the shoots being so well defined and showy would not diminish at 1100 ft. The ore is found on the contact of the conglomerate rock and the schist and one big ore-shoot at least has failed to turn up at the bottom level, while an intermediate level 50 ft. above has only alighted upon a small vein. It looks as if an orebody ranging for over 30 ft. in width has tailed out. The other shoots that have been cut at depth show some sign of contraction so it has to be admitted that developments at 1100 ft. are not altogether satisfactory. While this is so the company is doing a good deal of prospecting at the Mount Balfour field, some little distance away from Mount Lyell, with moderate results. The copper ore is rich but in a quartz gangue and has to be proved to carry down. Then the company has its superphosphate enterprise which has been a high success the sulphuric acid being manufactured from the low-grade pyrites from the Mount Lyell mine itself and from a splendid deposit of pyrite close to Zeehan in Tasmania.

Litigation of the most extensive nature is pending over the patent rights to the so-called flotation processes. The pioneer was one Potter, a brewing chemist and his 'hot acidulated solution' patent has been upheld by the High Court of Australia. Then there is the Elmore vacuum patent, the Minerals Separation (Cattermole patent), and the De Bavay 'surface tension' flotation process. The Broken Hill Proprietary Co. uses the Potters process, the Sulphide Corporation, the Minerals Separation, the Zinc Corporation the Elmore, and the Amalgamated Zinc the De Bavays.

Potters people are attacking the Minerals Separation company and the Sulphide Corporation the Minerals Separation is tackling the Amalgamated Zinc (De Bavays), which holds an option over the Potters, and the Elmore people are understood to be proceeding against the Minerals Separation company. The right thing to do of course would be for the contestants to amalgamate, but they are all cock-sure. The prize in front of the winner is immense, and lawyers and patent agents don't, as a rule, advise a non-fighting attitude.

TORONTO, CANADA

Cobalt Mines. — Porcupine. — Gowganda. — Government Geological Work.

The principal feature lately in connection with Cobalt has been a discovery on the Little Nipissing, which has had the unusual effect of sending the stock up several points on a generally quiet market. The discovery was made 800 ft. out under the lake at a depth of 236 ft. in the drift off the winze, which is now 50 ft. farther down. The vein is 2 ft. wide with a 7-in. pay-streak yielding rich ore. The find is in the Keewatin formation, and in view of the results of development in this formation in the Temiskaming this is regarded as favorably significant. The latter company has also been coming into favor recently, good ore having been extracted at the 500-ft. level. The anunal report of the Kerr Lake is somewhat of a disappointment as foreshadowing a reduction in the dividend rate unless production is increased. The net revenue of the year ended August 31 was $1,542,194, and the expenses $343,974, leaving a balance of $1,198,220 out of which dividends were paid amounting to $1,050,000. The surplus of $148,220 shows a decrease of $480,827, as compared with the previous surplus. The total production of silver was 3,046,295 oz., and the total cost of production 13.72c. per oz., the mining cost being 7.54c. per oz. At the Ophir the shaft is down 300 ft. with a 10-ft. sump, and active work has been started cross-cutting at the 300-ft. level to pick up the veins opened on the 200. The Hargrave is driving a drift from the main workings of the 375-ft. level on No. 3 vein to reach an orebody which has been worked on the Kerr Lake up to the Hargrave line, yielding rich ore. Shipments are being continued from No. 1 vein. The Provincial shaft No. 2 now down 200 ft. is being sunk 75 ft. farther. J. Reddington, formerly of the Coniagas, is in charge of the mine which will shortly make shipments of high and low-grade ore. The Trethewey has declared a 10% dividend being the first payment this year.

The Porcupine camp is attracting more attention just now than Cobalt, several important transactions in claims indicating that large capitalists are being interested having been reported though details are not available. A recent investment by a syndicate of British capitalists is stated to involve about a million dollars. At the Crown Chartered mine development is progressing rapidly. A crosscut is being run at the 70-ft. level to pick up a rich vein found on the surface. On the Armstrong-McGibbon property immediately adjoining a vein with a good showing of gold has been found, which has been traced across the Crown Chartered. Several of the mine-owners are now ordering machinery in view of the approach of cold weather which will render it possible to bring in heavy loads over the winter roads. The owners of the Vipond have purchased a plant which is now on the way, and the Foster, the Dome, and others are arranging for equipment.

Activity prevails at the Gowganda camp. The Reeves Doble, the shaft of which is down 215 ft., has bought about 20 tons of machinery including a mill with four Nissen stamps. The plant is not in operation, but when it starts is of sufficient capacity to supply some of the other properties with compressed air. The company has bought 15,000 tons of milling ore ready for concentration. The Millerette is preparing to put in a concentrator. The Boyd-Gordon is getting out good ore. Several finds at the Bartlett have been reported as the result of trenching operations. The latest discovery averages two to four inches in width and contains 3000 to 4000 oz. ore. There are also good reports from the Elk Lake district, where the Moosehorn and Silver Alliance are both preparing to make shipments of high-grade ore.

The exploring expedition sent by the Quebec Government included J. C. Gwillim, professor at Queen's University, Kingston, and A. E. Barlow, of McGill University, Montreal, has returned with a large assortment of mineral specimens after spending over three months in the wilds. These will be assayed and tested, and until the results are known and reported the members of the party are disposed to be reticent in expressing any definite opinions as to the mineral value of the region, beyond a general statement that some of the rocks appear to be highly mineralized. M. B. Baker, professor at Queen's University, commissioned by the Ontario Bureau of Mines to report on the alleged discoveries of coal on the Metagami river in northern Ontario, has found them to be practically valueless commercially, being merely a poor quality of lignite, much broken and folded, and non-continuous. Work at the Brazeau coal mines in Alberta to the west of Edmonton, in which the Canadian Northern railway is extensively interested, has been suspended. The reason is that the plans of the railway for a line to reach the coalfields were not approved by the Canadian Railway Commission, and that they could not therefore proceed with the construction of the road. The mines have been closed until spring.

GOLDFIELD, NEVADA

Bullion Output.—Consolidated Improvements.—Florence.—Combination Fraction.

A statement of John L. Considine, the Nevada State license and bullion tax agent, who has been in Goldfield on official business, declares that the bullion production of the Goldfield district for the past quarter was nearly 50% greater than for the preceding quarter, and that of the Tonopah district exceeded the prior similar period by approximately 100%. He predicts that the current year will establish a new record in both districts for the volume of their bullion output. The Goldfield Consolidated Mines Co. is reported to have been treating at times lately a tonnage closely approaching 900 tons per day with the usual high recovery of gold. New installations of hoisting and other machinery and construction of new departments, are nearing completion and all will be finished before the end of this month when some heavy items of expense will be eliminated and important economies effected in the use of the new departments, particularly by the aid of the storage battery plant. This will obviate the possibility of extended interruptions in operating hoisting machinery and lights through the shutting off of the power supply from the main line that brings the current from Bishop creek. Electric storms in the mountains through which the line passes have frequently caused the burning out of transformers and brought about a complete cessation of all such operations for several hours at a time. The storage battery plant will carry a normal load of 2500 hp. and will permit of the continuous lighting of all parts of the plant and the working of hoists for several hours without any power from the main supply line. The management is now preparing to install three new electric hoists, that at the Clermont to be of 250 hp., and those at the Mohawk and Laguna to be of 150 hp. each. These will replace steam power at the Mohawk, compressed air at the Clermont, and a small electric hoist at the Laguna. Other new departments in course of construction include an electrical supply building, transformer houses of large capacity for distributing the power to various points, a new and enlarged refinery building at the mill, a round house for the engines of the company's standard-gauge railroad, and a complete assay office and chemical laboratory. The recently exposed orebody on the 1000-ft. level of the Clermont is said to be maintaining its early promise and the drift has progressed for over 100 ft. in ore along the strike of the vein. The relation of this ore-shoot to that originally found on this level, farther to the north and east, has not yet been determined but the ore,

averaging around $65 per ton and containing many seams of high grade, is pronounced to more nearly resemble that of the Mohawk, particularly that of the rich stopes above the 500-ft. level, than the general run of Clermont ore. Raises will be driven from this level to demonstrate the extent of the new discovery. A good showing is being made in the orebody exposed between the Mohawk and Red Top shafts and now opened on the 600-ft. level, 150 ft. below the point of first discovery. Some of the richest ore mined recently on Consolidated territory has come from the upper levels of the Combination mine in territory west of the main workings and near the January. Excellent results have attended the opening of the great Hampton vein on the deepest levels and at a depth of more than 100 ft. below the floors of the Hampton stope.

The Florence Goldfield company has completed the work of enlarging the main shaft to the bottom, a depth of 530 ft., and the shaft has been re-timbered throughout. Pipes have been extended to the bottom from the compressors and machine-drills will at once proceed to sink the shaft to a depth of 1000 ft., opening stations and installing skip pockets and ore-bins at intervals of 50 ft. Two automatic skips of three tons capacity are being installed and are interchangeable with cages. Waste will be hoisted from the deeper levels to those above and will be used in back-filling the abandoned and worked-out stopes. The mill is treating from 140 to 150 tons per day and while the mill heads have been below the normal it is announced that treatment is being effected at a low cost and a satisfactory profit being made. From all parts of the mine ore will be hoisted through the main shaft directly to the bins and the aerial tramway will be abandoned as ore from the Little-Florence lease workings and those of the old Rogers lease can soon be trammed to the shaft on two or three levels. Work is in progress at the northern part of the Florence near and under the workings of the bonanza Reilly lease where a large body of good milling ore has been exposed on the 350-ft. level.

The Combination Fraction continues to treat from 50 to 80 tons per day at its leased mill and development in the mine is said to be yielding satisfactory results, particularly on the 500-ft. level. A report that the Nevada-Goldfield 20-stamp mill, leased by the Fraction company, was to be taken from that company and leased to the Jumbo Extension company was apparently inspired by the New York firm of brokers who have been conducting a bull campaign in this stock and who were raided a short time ago at the instance of the postoffice authorities. It is said that the estimates of ore in the Vinegerone fraction are greatly exaggerated.

BUTTE, MONTANA

International Smelting Co.— Anaconda. — East Butte. — Boston & Corbin.

According to talk of mining men who have smelter arrangements with the International Smelting Co. and allied smelting interests like the Amalgamated, the fight between the International and the American Smelting & Refining Co. is more bitter than the public has been understanding. With the erection of an International smelter in the Ely district, as contemplated, every field of the A. S. & R. except Colorado will be invaded by the new smelting company. Colorado is not an inviting field for the Cole-Ryan interests, as ore production has fallen off so greatly there that the Guggenheims can operate only three of their seven furnaces in that State. The International and its allied interests now have the big smelter at Anaconda, one in Great Falls, the new plant at Tooele, Utah, the Calumet & Arizona at Douglas, Arizona, and the Cole-Ryan plant at Cananea, Mexico, these covering the entire field from which the American Smelting & Refining Co. draws its ores. When the latter had a clear field its charges for ore treatment were high, allowing a profit of $4 to $6 per ton. The excessive smelter charges made many enemies among Western miners, and the International interests have a big advantage in that fact alone, while its smelting plants are all new and modern. With these advantages the International will be satisfied with profits of $1 to $1.50 per ton, and its purpose evidently is to prevent the American Smelting & Refining Co. from renewing any of its old and highly profitable contracts. The days of enormous smelting earnings are over. The best contract the American Smelting & Refining Co. has left is that of the Utah Copper Co., and it is said that the profits made by the smelting company are enormous and would shock stockholders of the Utah Copper if they knew their extent. The International interests expect to treat about 5000 tons per day of custom ore. At a profit of only $1 per ton it would amount to $1,825,000 in one year. It is expected that this will represent the tonnage the American Smelting & Refining Co. will lose, upon which it has been making a profit, at $5 per ton, of $9,125,000.

B. B. Thayer, president of the Anaconda Copper Mining Co., is in the city inspecting the properties of the company. Mr. Thayer has only just started his work of inspection and therefore is not in a position to give out any information as to the condition of the mines, although he did say that he expected to find them all in excellent shape. "The copper market conditions are slowly improving," he said in reply to a question, "and I don't believe it will be many months before the market is nearly normal again. The consumption of copper today is the largest in the history of the world, and in both England and Germany the demand is increasing. All the large producers have recognized the necessity for a little ease up in the production and this is already having the effect of considerably reducing the surplus. This together with the increase in the consumption will mean that it will only be a few months before the surplus is practically wiped out. The copper market of the future looks bright and when once the mines get back to their normal output I don't believe a necessity for a curtailment will arise again, at least not for a long time anyhow." The St. Lawrence mine of the Anaconda group is to go deeper. A crew of men is now engaged in sinking the shaft to 2300 ft., which is 200 ft. below the present level. Although the mine is not hoisting any ore, quite a force of men is at work between the re-timbering of the shaft and the shaft sinking. The work of securing a good foundation for the new ore-bins to take the place of the ones which fell down a short time ago, has been proceeding rather slowly and it is believed now that at least two months will elapse before the St. Lawrence will be in a position to resume operations.

One of the furnaces of the Pittsmont smelter of the East Butte company has been closed, due to the fact that the Butte-Ballaklava and Ticon companies are not shipping the ore to the smelter they formerly did owing to the actions brought against these companies by the Anaconda company which caused considerable curtailment in the output of the mines of the companies named. Previous to the forced curtailment of the Butte-Ballaklava and Ticon mines the two concerns shipped in the vicinity of 6000 tons of ore per month to the smelter. The one furnace now being operated at the Pittsmont is treating some custom ore and only enough from the company's own mines is being hoisted to keep the furnace up to its capacity. Development is going on quite extensively and a large amount of ore is being blocked out, but no attempt is to be made to increase the production until there is an improvement in the market conditions. It is stated on very reliable information that the East Butte is earning more than operating expenses, which is considered very satisfactory under existing conditions. There is no authentic information yet forthcoming from the Butte & Superior as to how the bonds are being taken or whether W. A. Clark has consented to accept the offer of the directors to treat a certain quantity of ore provided he will take his full quota of bonds as allowed him in proportion to the amount of stock he holds. Mr. Clark appears to be acting in the matter in a kind of indifferent manner, due no doubt to the fact that when he offered to put a large amount of money into the treasury of the company his offer was rejected as the conditions were not con-

sidered acceptable. At the time in question he promised to treat the ore of the company if given him and guaranteed a certain net return, much greater, it is said, than the company was receiving from the treatment of the ore at the Basin concentrator. Mr. Clark has a lease on the concentrator part of the reduction works formerly owned by him but dismantled after being purchased by the Amalgamated Copper Co. The ore from his Elm Orlu mine is not nearly enough to keep this concentrator supplied.

The Boston & Corbin company which operates in the Corbin district, has enough money in its treasury to carry on development for a year without shipping a single ton of ore. However, it is believed that the company will ship regularly in the near future as some fine orebodies have been opened. The management is highly pleased over cutting the Bertha vein on the ninth level. It was discovered 250 ft. farther east than any ore yet found on the upper levels and is said to indicate that the ore-shoot on the ninth level should be at least 1500 ft. long as against 550 ft. on the third, 900 on the fifth, and 1250 on the seventh. On the upper levels the vein averaged from four to five feet in width, whereas on the ninth, so far as opened, it is about 11 ft. wide. The force in the Barnes-King mine and mill has been increased from 25 to 40 men. The Keating Gold Mining Co. in the Radersburg district, which is at present shipping ten cars of ore per week to the Pittsmont smelter, expects to double that amount in the very near future. The development is reported as encouraging. Some copper ore of a high grade has recently been found, but there has been no decrease in the gold value.

NEW YORK

Influences on the Market.—Inspiration.—Calumet & Arizona-Superior & Pittsburg Consolidation.—Cactus.

The elements which have been retarding market progress, uncertainty as to the action in regard to the tariff, the coming Supreme Court decisions, the political campaigns in progress in the various States are still making their weight felt, though there are many strong indications of real recovery the moment conditions will permit of a broadening of market operations. The volume of trading on the New York Stock Exchange is increasing materially and there is much impatience expressed generally that such a deadlock as exists at present should maintain an unbroken hold for so long. In the mining markets the October report of the Copper Producers' Association was received with much acclaim, as a demonstration of the success of the curtailment policy. A decrease in surplus of 20,087,536 lb. compared with stocks on hand September 1, showing a net increase as compared with January 1, of 7,027,603 lb., has already given courage to the producers and strengthened their theory as to the stabilizing of the metal market. This better feeling created has been reflected in the stock issues and some strong advances have been made. Many followers of the copper list lost heavily by reason of the Ely Central collapse.

It has been evident for some little time that there were some developments in Inspiration. An advance of over three and a half points was made without apparent crowding and without any concurrent news from the mines. The shares sold above $10 and the issue was the feature of the market. It now transpires that a deal has been completed for the $2,000,000 of stock remaining in the Inspiration treasury, and another step toward a final merger of the porphyries made at the same time. The 200,000 shares of stock mentioned was taken at par, $10, which was considerably above the current market price at the time, by a group of copper interests, including Hayden, Stone & Co., who act for the Guggenheims and who were active in the promotion of Utah and Nevada Consolidated, and who now look after the financing of Ray Consolidated and Chino. Thompson, Towle & Co., who have acted for the principal financial interests in Inspiration heretofore and in Mason Valley, also have a large share in this underwriting. The trade is important, not because of the amount involved, but more particularly because it marks the growing community of interests in copper. Every important step, in the financing of the principal developing coppers, made during the past year has been directly in line with plans for eventual huge consolidations or toward such a growing common interest as will in the end render the copper merger a mere outward formality. The deal just described brings the Inspiration, which adjoins the Miami, at Globe, Arizona, and the Mason Valley at Wabuska, Nevada, definitely into the Utah Copper Co. family. In looking over the important developing coppers there is hardly one left now which is not definitely allied with some one of the larger copper interests, and it is easily seen that by process of elimination such group of producers is being constantly reduced. Inspiration's treasury is provided for at least two years to come, and the immediate plans are for the erection of a 5000-ton concentrating mill to go into operation as quickly as possible. Developed ore is said to amount to 10,000,000 tons, with a probable tonnage estimated at 40,000,000 to 50,000,000 tons.

It will be remembered that when the producers were conferring in London, a share in the negotiations was at all times credited to the Rothschilds; the latter holding control of the Rio Tinto of Spain, and being parties to the curtailment agreement, part of which was mentioned so encouragingly and so diplomatically denied almost in the same breath after the conferences were closed. Evidently the Rio Tinto management is curtailing in all directions. Production has been cut some 15%, and now dividends are reduced from 30s. per share six months ago to 25s. for the current distribution, which is practically in the same ratio.

In the annual report of the Rio Tinto Company, Ltd., the directors take a very hopeful view of the situation and express the belief that working in conjunction with the American producers, the curtailment policy now in force will soon strengthen the industry and remove the depressing element of overproduction. The output for the year is estimated at 4,480,000 lb. of copper. A special meeting of the stockholders of the Braden Copper Mines Co. has been held and the issuance of the $2,000,000 second-mortgage bonds authorized. Of these one-half are to go to the shareholders at par and the proceeds devoted to immediate enlargement of the company's plant. The balance of the bonds are to be held until operations warrant further expenditures; among other things, the contemplated erection of a leaching plant. There is some harsh criticism made of the Federal Mining & Smelting Co., which controls the lead-silver output of the Coeur d'Alene aside from the Bunker Hill & Sullivan property. As in the case of the Granby, the shareholders have been in receipt of dividends regularly, but have had very little information, only to wake up to a situation where diminished ore reserves compel the development of new ground or an eventual cessation of profitable work. This is not in itself so much ground for complaint, since every mining property must sooner or later reach this stage, but while the present report of the Federal Mining & Smelting Co. is ample in detail, it conveys the true state of affairs to the shareholders a little tardily. In the meantime, not only the ore reserves, but the working capital has diminished and the developing of new properties must call for the expenditure of considerable sums. In the case of the Granby it cannot be said that the recent resignations cleared the air. The public impression seems to be that such resignations were accepted in the interests of peace. The reports on the property have not been at all satisfactory, and the undertaking of the management to acquire and exploit new ground in the hope of finding new orebodies is recognized as highly problematical. For the present at least, Granby must be counted as having but a few years of life, after which its splendid plant will be without ores. The salient fact emphasized in these occurrences is, that if the shareholders were vouchsafed the important vital information to which they are entitled, there would be fewer disgruntled stockholders and little or no necessity for humiliating resignations under fire.

Conditions at the Greene Cananea are improving. The long task of rebuilding the scrap heap turned over by

William C. Greene is almost completed and the company is now paying its own way. When everything shall have been done that is planned, it is hoped to get copper costs down to 9c. per pound. The reconstructed plant of the Greene Cananea will be ready to handle the Miami concentrate by the time shipments can be made and the output of the Sierra de Cobre property recently purchased from the Phelps-Dodge interests will be increased so that the plant can be kept running at capacity. James Douglas, of Phelps, Dodge & Co., and L. D. Ricketts, of the Greene Cananea, have just completed examinations and reports upon the Calumet & Arizona and the Superior & Pittsburg. These reports are to be used as a basis for a merger to be worked out consolidating the two mines. There has been some friction, it is said, as to the ratio of exchange between the larger holders in the two companies, Calumet & Arizona owners demanding four shares for one, the Superior & Pittsburg interests offering two shares for one. To adjust these differences an independent report was decided upon. When the consolidation was first considered it was thought the Chemung would be included, but as yet there has been no definite announcement in this regard.

The Eastern holders of Cactus stock are somewhat dismayed by the recent developments at that property as outlined in the report of C. W. Pritchett, consulting engineer. The market effect has been a decline to 61c. from a high figure of $7 in January last. The Cactus is ten miles distant from the Miami. The orebodies as described by Mr. Pritchett are fairly large in area, but have not held in depth. It will require some months of drill work to fully determine whether Cactus is to make a mine or not. The apparent failure of the work so far does not mean that the property is to be classed wholly as a disappointment, as only a small part of the Cactus territory, which consists of 650 acres, has been systematically prospected. The deal between John T. Milliken, of St. Louis, and the Consolidated Gold Fields of South Africa for the sale of a controlling interest in Mr. Milliken's Golden Cycle mine at Cripple Creek has been definitely declared off. However, Mr. Milliken and his associate, Thomas H. Rea, of Chicago, have succeeded in interesting the Consolidated Gold Fields people in the new camp of Porcupine, having sold them two claims aggregating 320 acres. At the same time the Consolidated Gold Fields has greatly broadened its field of operation by acquiring a large interest in the Oro Grande company at Guanajuato, Mexico. The Oro Grande is a recent organization of the Securities Corporation, Limited.

LONDON

Consolidated Gold Fields Groups. — Consolidated African Copper Trust.—Bechuanaland Exploration Co.—Penhalonga Company.

One of the most interesting groups of gold mining companies owned in London and operating in New Zealand is that of the Consolidated Gold Fields of New Zealand, which was formed in 1896 to acquire properties in the Reefton district of New Zealand from David Ziman. The chief mine operated by this company is the Wealth of Nations; the Progress and the Blackwater mines were floated as separate companies. Ernest W. Spencer is general manager for the group of mines. During 1909 the Wealth of Nations treated 15,577 tons of ore yielding bullion worth £22,481 by amalgamation, and the cyanide plant treated 9590 tons and produced bullion worth £5877. The total yield was £28,358, or 36s. 5d. per ton, and the cost was £12,408 or 15s. 11d. per ton, leaving a profit of £15,950 or 20s. 6d. per ton. The reserve on December 30 was estimated at 36,000 tons, but Mr. Spencer points out that the ore is difficult to measure. During the year a tube-mill was erected, but the accessory slime-plant was not completed until after the close of the year. The company also owns the Golden Fleece and Humphrey's Gully mines, which are let to tributors, and £2916 was received from this source during the year. In addition £14,005 was received as dividends from the subsidiary companies. The net profit for the year was £29,607, out of which £4004 has been written off for depreciation, and £12,118 has been distributed as dividend, being at the rate of 5%. Since the close of the year two other dividends of 5% each have been paid. The Wealth of Nations is a small mine and it is advantageously worked, but it is not quite big enough for the capital, £242,377. The directors call attention to the fact that the founder's share will soon be drawing one-quarter of the profits; according to the articles of association the founder takes 25% of the profits after 100% has been paid on the ordinary shares. So far 82½% has been paid in cash and 10% in shares in the Progress mine, and the directors are in favor of exchanging the founder's share for 80,000 ordinary shares. During the year L. Ehrlich has been elected a director, and E. T. McCarthy is acting as David Ziman's alternate on the board during his absence in New Zealand.

The Progress Mines, referred to above, is a subsidiary of the Consolidated Gold Fields of New Zealand and was floated in 1896. During the last few years the development has not been sufficient to keep the mill, in which there are 65 stamps, fully employed. During 1909 the battery treated 35,414 tons, producing gold bullion worth £42,978, and the cyanide plant treated 25,025 tons of sand with a recovery of bullion valued at £9052. The total receipts were £52,030 or 29s. 5d. per ton, and the working cost was £46,423 or 26s. 3d. per ton, leaving a profit of £5606 or 3s. 2d. per ton. Other expenses were administration £4977, taxes £2394, depreciation £4336, and expenditures on development £4572. On the other side of the account are dividends on Blackwater shares, £4346, and items of interest and profit on the sale of shares, and the final result of the year's operations was a loss of £1894. The year commenced with a balance in hand of £28,141, so a dividend of 5%, absorbing £13,750, has been paid and £12,496 carried forward. The smelter for the treatment of concentrate, slime, and accumulated residues was completed toward the close of the year. This material contains a good deal of arsenic and antimony and requires careful roasting.

The Blackwater Mines, another subsidiary of the Consolidated Gold Fields of New Zealand, is fulfilling the promise made on flotation in 1906, and the developments and the results of metallurgical work are highly satisfactory. Milling commenced in August 1908. During the year 1909, the ore sent to the mill was 29,955 tons and gold worth £66,712 was recovered by amalgamation; the cyanide plant treated 19,635 tons and produced gold worth £6569. The total yield was worth £73,281 or 48s. 11d. per ton, an increase of 10s. per ton over the figures contained in the report for 1908. The cost at the mine was £25,221 or 16s. 10d. per ton, leaving a profit of £48,060 or 32s. 1d. per ton. Out of this, London expenses, rates, and taxes were paid, and depreciation and development were allowed for, so that the net divisible profit was £36,853, and, after deducting £6744, the adverse balance a year ago, £30,109 remained to the credit of profit and loss. The dividend absorbed £12,498, being at the rate of 5%, and £17,610 was carried forward. The ore reserve on December 31 was 69,000 tons; owing to the irregularity in the width of the vein it is not easy to make an estimate of this. The country rock also causes difficulty owing to its friable nature. The tube-mill started work in August 1909 and the slime plant was completed later. The latter has not yet got to work owing to lack of power, and a gas plant is being provided to make up for the deficiency of the water-power on which the mine depended.

The Consolidated African Copper Trust was formed in 1902 to acquire a number of copper properties in various parts of Rhodesia and adjoining countries belonging to the Consolidated Gold Fields of South Africa, the London & Johannesburg Trust, and other groups. The control was in the hands of the first named. So far the chief subsidiary flotation has been the Edmundian Copper Co., which was formed to acquire the mine of that name over the border in Mozambique territory. The Consolidated African Copper Trust has been in financial difficulties for some time owing to the development of properties taking more money than was expected and owing to difficulties at the Edmundian due chiefly to faulty construction of plant. In order to put the company on a sound basis a scheme of recon-

struction has been proposed, and accepted by shareholders, whereby the London & Johannesburg Trust guarantees £75,000 of new capital and acquires the control. By this scheme the shareholders take 558,000 new shares of 5s. each in exchange for a similar number of £1 shares; 300,000 new shares of 5s. each are being offered for subscription and will be absorbed by the guarantors or the shareholders, the subscribers having a call at par on an equal number of shares for two years; 160,000 shares are being issued in satisfaction for loans advanced and 80,000 are being held in reserve. The loans were advanced for the purpose of developing the Umkondo mine and for keeping the Edmundian company going. The future policy as outlined by H. A. Piper is to keep the Edmundian mine in order, and to bring the Umkondo and Alaska properties into a shape suitable for flotation. Mr. Piper, though dissatisfied with the Edmundian plant, thinks highly of the mine. As regards the Umkondo, which is in the Victoria district, faults and dikes have interfered with development, and capital is required for further work. The reserves are estimated at 90,000 tons averaging 8%. The Alaska property contains 300,000 tons of 3% ore and a flotation method of concentration is to be adopted. A number of samples will be crushed and treated by several methods to ascertain which will give the best results.

Another development company concerned with copper properties in South Africa is the Bechuanaland Copper Co. This company was formed in May 1909 by the Bechuanaland Exploration Co. to acquire the license to work the Bushman, and other claims, 120 miles southwest of Bulawayo. The license is held from the British South Africa Co., which takes 50% of the profits. The capital of the company is £135,000 in 270,000 shares of 10s. each. The purchase price was £10,000 in cash and 30,000 shares; 120,000 shares were offered to the public, and were underwritten partly by the promoters and partly by L. Hirsch & Co., whose consideration was a call at par on the remaining 120,000 shares. The properties are situated on old workings and operations have been confined so far to the Bushman. The development work was started by S. C. Dyer and afterward let on contract. E. Jorissen is the consulting engineer. During the year ended May 31, 2382 ft. of work was done on eight shafts and four levels. Mr. Jorissen shows that the sulphides have been distributed throughout dolomite and quartzite by means of veins of pegmatite and that the ore is found in lenses. In many places galena has replaced the copper sulphides; calcite, graphite, and oxides and carbonates of copper are also found. He reports that the copper content varies, and he is of opinion that while the conditions are generally promising, much more prospecting and development will be required before the economic value of the deposit can be ascertained. As regards the graphite, this is found to exist in large enough amounts to give it a commercial value.

In a recent letter I gave an account of the condition of Penhalonga company which owns gold properties in the Umtali district of Rhodesia and is in the control of the Anglo-French-Farrar group. I mentioned that shareholders had not responded to a scheme for reconstruction based on the recommendations of H. A. Piper, the consulting engineer, and C. R. Pinder, the late manager. Another proposition has now been put before shareholders and adopted. This is a drastic reconstruction for both the debenture holders and shareholders. The capital of the new company is £110,000 in shares of £1 each; of these 66,450 go to the debenture holders, in the proportion of 1 share for each £3 debenture; 13,750 are allotted to present shareholders at the rate of 1 for every 20 shares in the old company; 27,500 are being offered to shareholders at 10s. each to present shareholders; and the remaining 2300 will be held in reserve. The issue of 27,500 new shares was guaranteed by some of the leading shareholders, so the success of the scheme was assured. This will provide working capital to the extent of £13,750, and the company has assets sufficient to bring the available funds to £21,000, the amount considered requisite for the further carrying on of development.

SALT LAKE, UTAH

Ohio Mill. — Bingham Butte Mining Co. Consolidation. — Bingham Mines Co.—Mining Suits.

The unusual records for tonnage which have been made by the Ohio mill have all been eclipsed by a recent day's run in which 2096 tons were put through. The rated capacity of the entire mill, only one-half of which is equipped, is only 2250 tons so that this one-half is handling almost as much as the entire plant was designed for. As pointed out in a recent letter the Ohio is well designed for crowding but there is some doubt as to whether the process is not being carried too far. The Bingham Butte Mining Co., of Bingham, has been reorganized as the Montana Bingham and equal exchange of stock in the two companies made. The reorganization was merely a matter of form. This company is driving an adit in the hopes of opening the Quinn fissure which cuts through the Utah Copper pit. It has been driven 400 ft. to date and it is expected to cut the fissure within the next 200. The work on the adit of the Utah Metals Co., which is allied to the Montana Bingham, is progressing at the rate of about four feet per shift, one day's work recently covering 13 ft. 8 in. The 1000-ft. level of this property is being cleaned out for the purpose of prospecting some of the fissures cut on the upper workings. Work at the Old Jordan, which was closed down while all of the machinery was given a thorough overhauling, has been resumed. It is generally understood that it is the intention of the company to increase production from the mine and that the capacity of the zinc plant at Midvale will be enlarged accordingly.

The moving of the buildings of the Bingham Mines Co. has been completed and Copper Center gulch is now open to the Utah Copper Co. as a dumping ground. The removal of the buildings makes it necessary for the company to extend the Niagara adit as a working entry and it will be about three months before the mine is shipping again.

Arguments in the case of the Silver King Consolidated *v.* Silver King Coalition have been begun in the local Federal court and the end of the long-drawn-out case is in sight. The suit is for an accounting for ore illegally extracted by the defendant company and involves about $5,000,000. Defendants have admitted that the ore was extracted and the only question seems to be as to the amount of damages. The case will be appealed in all probability. A similar suit has been brought by the Moscow Bonanza against the Moscow. The shaft of the latter is within a few feet of the boundary line with the Moscow Bonanza and the latter company alleges that ore has been taken from its property and hoisted out of the shaft. The Cedar Talisman has made a discovery of 50% zinc ore on the 125-ft. level. The vein will be followed up to the surface and down to the 500. The Consolidated Mercur has issued its annual report for the fiscal year ended June 30. It shows a total production for the year of $613,148.92, net profits of $16,537.08 and cash balance of $91,566.89. The mill treated an average of 638 tons per day, mining costs were $1.48, and milling costs $1.15, total expenses being 1c. per ton more than the previous year in which 50,000 more tons of ore were treated. The principal reason for the small profits is the decrease in the value of the ore. The showing is a good one considering the many difficulties that have been met.

The Escalante mine, fourteen miles southwest of Modena, is closed for the second time on account of water in the shaft. The original shaft was abandoned after a 300-gal. pump had failed to lower the water more than one inch in 24 hours and on the advice of an engineer the new shaft was started. This has struck water on the same level as the old and the mine is closed, at least temporarily. After the expenditure of $300,000 in development the Log Cabin, in Marysvale, has made its first find. A 30-ft. vein has been cut which assays $8 to $10 the entire width. The discovery was made at a vertical depth of 1000 ft. so that good stoping ground is assured. The mine manager and superintendents of the properties in the Tintic district recently visited the new power plant of the Centennial-Eureka on the invitation of Robert A. Brown, the superintendent.

General Mining News

ARIZONA

COCHISE COUNTY

The adit on the Santa Fe claim of John A. Duncan opened a vein of copper ore when in 80 ft. on a contact of limestone and diorite. The property is in the Paradise district and the ore assays 7% copper with $4 gold.——The east drift on the 200-ft. level of the Calumet & Arizona is in 90 ft. and it is the intention of the operators to start cross-cutting if the shoot is not picked up soon.——Development at the East Side mine, six miles from Bisbee, is opening a good grade of ore. The property was re-opened last March after a period of inactivity. Operations are being carried forward from the two shafts that were previously sunk on the claims. The ore under development averages $25 per ton. ——A new boiler and compressor has been installed at the Apache camp of the Copper Queen company and the work of prospecting the ground is being rushed. There are about 40 men at work on the claims and the results are said to be excellent.

GILA COUNTY

(Special Correspondence).—The winze on the 500-ft. level of the Telfair shaft at the Arizona Michigan property is down 100 ft. Up to a depth of 70 ft. the winze was in the foot-wall of the vein, but for the last 30 ft. vein matter has been cut and the winze is now in an almost pure hematite. A drift is being driven east on the vein at the level of the collar of the winze and has progressed to date 95 ft. from the Telfair cross-cut. This drift is kept close to the foot-wall of the vein and is also cutting some hematite stringers which are impregnated in places with copper carbonate. It is the intention of the management to drive west on the vein and also to cross-cut to the vein matter at the bottom of the winze.——The diamond-drill at the 660-ft. level of the Superior & Globe shaft is at a depth of 310 ft.——Structural work at the Miami plant is practically complete with the finishing of the sampling plant and some steel work on the power-house. Attention is being mainly directed to the installation of power and milling machinery. The underground development for the week has amounted to about 300 ft. The three churn-drills are still operating on the Climax. St. Johns fraction, and Flat Top claims and are making 20 ft. per drill per shift of twelve hours.

Globe, October 17.

MARICOPA COUNTY

A 6-ft. vein of copper ore has been found on the Wilson group in the Salt River mountains near Phoenix, and an open-cut is being driven along the vein. The ore also assays several dollars in gold.

MOHAVE COUNTY

Work is being centred on the new shaft at the Ruth mine in the Silver Creek district, and it is expected that the big orebody will be opened in a short time.——The Needles Mining & Smelting Co. is getting things in shape to begin shipments of ore from the Banner mine in the Stockton Hill district and the Tennessee mine at Chloride. The former will ship about one car per day and the latter two, for the present, the properties being under development that will eventually mean a much larger tonnage.—— The Tom Reed shipped a $45,000 gold bar early in the month, the result of a three-weeks run of ten stamps.—— The stope from the second level of the C.O.D. mine has opened some exceedingly rich ore assays of several thousand dollars per ton being obtained.——The 4-stamp Nissen mill of the Dixie Queen Mining Co. has been completed and will be in operation in a few days. The company has been developing the property for several years and has a large tonnage blocked ont ready for the new plant.——The Home Pastime Mining Co. has been organized to complete the development of the Home Pastime group of claims in the Mineral Park district. The company is capitalized for $250,000 and will begin work immediately on the property.

PINAL COUNTY

Two churn-drill holes at the London-Gila property near the boundary of the group have cut copper oxide ore and the drill has been moved to the central portion of the ground.——J. Parke Channing, who is consulting engineer for the General Development Co., has recommended that this company give up its option on $2,000,000 worth of convertible bonds of the Ray Central Copper Co. The original option expired last March but since then has been extended to December 1. The option price of the bonds was 80 and $100,000 worth have already been taken. J. A. Lewisohn is president of the General Development Co., and it is thought that the turning down of this option will result in the resignation of the Lewisohn interests from the board.

YAVAPAI COUNTY

After ten years of idleness the Jessie mine at Chaparal is being re-opened and put on the producing list, a carload of ore having been recently forwarded to the Humboldt smelter. The Jessie has an excellent record for production in the early nineties.

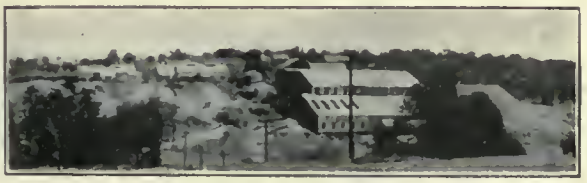
YUMA COUNTY

The first consignment of ore from the Wardwell-Osborne group seven miles east of Parker has been forwarded to the Humboldt smelter and teams are busy hauling ore from the mine to the railroad. B. H. Bennetts, manager for the Consolidated Arizona Smelting Co. operating the smelter at Humboldt, has been in the Parker district for the past few days contracting for the ores from that neighborhood. ——The shaft at the Silent King group near Alamo springs has been sunk to a depth of 80 ft., the ore averaging about $75 per ton and the owners are planning on installing a gasoline hoist.

CALIFORNIA

AMADOR COUNTY

Seventy-five men have been laid off at the South Eureka mine near Sutter Creek while the shaft is being repaired and new rail laid for the skip. It is thought that this work



South Eureka Mine and Mill.

will take about three months to complete. Earl Liversedge and Vaso Vuscovich were thrown from the skip a few days ago and killed by falling to the bottom of the shaft. The former was a shift boss and the latter a skip tender, and the accident was caused by the skip striking a piece of loose iron at the 700-ft. level.

CALAVERAS COUNTY

(Special Correspondence).—The Lightner Mining Co. of Angels Camp has asked for a writ of prohibition in the Appellate Court at Sacramento to restrain the Superior Court of Calaveras from trying the damage suit of James V. Coleman against it for the recovery of $150,000, the value of a large amount of ore which he alleges said company extracted from his ground. Mr. Coleman has been pressing his suit for trial for some time and the company has been persistently seeking delay. The case was set for October 24 when an appeal was taken by the defendant to determine whether the case shall be tried next Monday or not. Mr. Coleman charges that delay is sought in order that the company may sell and thus avoid the judgment which it anticipates.

Angels Camp, October 17.

INYO COUNTY

(Special Correspondence).—A. J. McCone, of Reno, and W. H. Landers, have purchased and taken over the gold mine of the Reward Mining Co., situated ten miles from Independence, and four miles from Citrus station; they have

also purchased the Brown Monster property in the same district. The Reward mine is equipped with an air-compressor and drills; also a 20-stamp concentrating mill to which a cyanide plant is to be added. In the mine are 20,000 tons of ore estimated to assay $15 per ton. The property is to be operated by the purchasers and work will begin with a force of 40 to 60 men as soon as arrangements are made for electric power. The former owners were Philadelphia men.

Bishop, October 15.

MARIPOSA COUNTY

The Bullion Mining Co. has opened a shoot 150 ft. long on the American Eagle group near Exchequer which assays $32 per ton. B. R. Binns is superintendent.

NEVADA COUNTY

A 13-ft. vein is being opened on the Florida property on the south fork of the Yuba river that contains a high percentage of concentrate with a fair amount of free gold.——A. S. Wall, of North Bloomfield, has opened a good prospect of pay-gravel on his claims in that district. The raise from the adit driven in the bedrock has broken through into the gravel which pans well.

SHASTA COUNTY

(Special Correspondence).—The Balaklala company is running one furnace on ore from the Balaklala and Bully Hill mines, and the Cottrell fume-controller is giving excellent satisfaction, and work is to be resumed at the Balaklala mines.——The Mammoth Copper Co. is meeting with good results in the development of the Summit mine, important reserves having been recently developed, while the diamond-drill is exploring new ground.——Thomas W. Lawson, president of the Trinity Copper Co., recently informed stockholders that work would be resumed when copper advanced to 15c. According to the last report it requires $8500 per year to conduct the affairs of the company, although the property has been idle for two years.——The mill at the Victor mine is rapidly nearing completion and will be in operation within 30 days. Good ore is being extracted. The mine adjoins the Midas at Harrison Gulch, one of the best producers of high-grade ore in the county. The manager of the Midas mine last week discharged 20 miners on the charge of high-grading. Two of the men were detected in the act by the underground foreman. The superintendent estimates that $5000 has been stolen from the 600-ft. level in the past month.

Redding, October 15.

SIERRA COUNTY

The Lucky Strike group of claims three miles northeast of Forest is to be developed by a company which has been organized by A. Max. The holdings cover a strip 4500 ft. long and 600 ft. wide and include two parallel veins from the outcrops of which good assays have been obtained.——The breaking into the old workings of the North Fork property in re-opening the old incline to tap the Uncle Sam vein has stopped the work for the present on account of the foul air and gas in the old drifts. A blower is to be installed and operations resumed in a few days.——Eugene Brown and L. C. Hendry are sinking a shaft through the lava cap on Lucky Dog ridge to tap the north extension of the Eureka vein.——The Lucky Dog gravel mine which was bonded to F. W. Roher, lessee of the Omega, will be worked next spring in conjunction with the Omega.——A small hydro-electric plant has been installed at the mine of the Blue Channel Mining Co. for lighting purposes. The water was turned on and everything found to work satisfactorily.——The contractors at the Monte Cristo gravel mine are making excellent progress and have only about 40 ft. left to complete the work. Some of the old workings which were filled with water were tapped with a bore-hole and operations were stopped for a short time till that part of the mine was drained.

TUOLUMNE COUNTY

(Special Correspondence).—The Black Oak mine has been unwatered and sinking was commenced on October 17, with a crew of 12 men. The shaft is 1600 ft. deep and, it is understood, will be sunk to the 1800-ft. point.——The work of erecting a building for the 10-stamp mill to be installed at the Duffield mine, near Arastraville, has been completed. An electric motor to operate the air-compressor has been put in place.——A small mill is to be put up on the Old Dominion mine, the property of A. Baier and George Grant, situated near Columbia.——The old Mexican mine, near Jamestown, worked with great success in the early days by Mexicans, has been reopened by Miller & Roscoe.——Sinking has been temporarily discontinued in the Hancock shaft at Karnac and cross-cutting commenced at the 100-ft. level to tap the vein, which at a depth of about 50 ft. changed from vertical to 45° pitch. A mill is to be installed, the machinery for which is on the property.

Tuolumne, October 18.

COLORADO

CHAFFEE COUNTY

A new lease by local parties has been taken on the Belle of Granite mine, and work is again starting on this old property which will lead it back to the active list. The mine has been idle for several months, due to difficulties between owners and lessees. The property has produced a great deal of high-grade ore, in the mining of which all low-grade material was thrown on the dump in the belief that it was unprofitable. The new lessees, after thoroughly prospecting and sampling the dump, find that it contains ores assaying $10 to $40 per ton, all of which can be profitably milled. The mine is equipped with a 20-stamp mill and pipe-line. The dump will be run through the mill, as well as a large tonnage of ores of low value which are blocked out in the mine.

LAKE COUNTY

The end of the third quarter of the year finds the Leadville district in better shape than it has been since the slump of 1907. This condition is due to several incidents that have happened since the beginning of summer, among them being the opening of the great fissure vein of the Cleveland in the granite. This alone has been the means of a number of properties in the neighborhood resuming work and the starting of several new shafts: the connecting of No. 2 shaft of the Resurrection with the Yak tunnel, the sinking of the shaft beneath the tunnel-level, and the hoisting of ore and waste to the surface instead of hauling it out to the portal, a distance of nearly four miles. The finding of carbonate of zinc continues to interest many miners and much prospecting is being done for this new class of ore in other parts of the district outside of Fryer and Carbonate hills. It has been found in some claims on Iron, Breece, and Rock hills, and it is more than likely that it will be found in all parts of the district. Whether it will appear in such immense bodies as is in the Maid of Erin, Henriette, Adams, Wolftone, Waterloo, Morning Star, Evening Star, and Big Chief, and also hold up to the grade of 45 to 50%, development alone will decide. Another good discovery of carbonate of zinc is reported from the Stevens shaft, on Rock hill, ore being opened in three different parts of the property that assays 45 to 50% zinc. Shipments are being made from this find.——The Sugar Loaf adit has been completed to the 2700-ft. station, and it is still going forward at the rate of 100 to 125 ft. per month. The objective point of this adit is the Dinero vein, which soon will be reached, and is expected to yield large bodies of ore. Numerous veins and stringers have been cut in the course of development, the most promising of which will be prospected when the Dinero has been reached.——The Colonel Sellers promises to be a heavy shipper at no distant date, as driving soon will begin from the 400-ft. level to the upper orebodies, which are known to be large and of good value. Steel ore-bins are being erected and other improvements made. The company expects to ship in the neighborhood of 350 tons daily.

PARK COUNTY

The new pyritic smelting plant recently put in operation at Fairplay is successfully operating, and is treating a good

tonnage of ore, coming principally from the mines along the north and south forks of Mosquito creek. The Moose and Dolly Varden mines on Mount Bross, are also shipping to this smelter. The Mosquito district now has four producing properties which furnish practically two-thirds of the mineral output of the county. The building of the smelter has had a stimulating effect upon many properties here, most of which are low grade and in a condition of non-production because of a lack of reduction works, the ores being of too low a value to withstand shipment to distant smelters. Several former producers are now expected to become active again, and the outlook for a larger mineral product this year than in any former season is good.

TELLER COUNTY

A rich seam between three and four inches wide has been opened in a 4-ft. vein on the 1000-ft. level of the Trilby property in the Cripple Creek district. The streak contains both free gold and sylvanite and assays over 30 oz. gold per ton. There are seven shoots now opened in the Trilby workings and shipments are being forwarded regularly.——Fogleman & Lee, operating on blocks 14 and 15 of the El Paso ground, have opened a shoot on the third level north of the shaft that assays $30 to $35 per ton.——Carl Johnson, lessee of the Maggie claim between Raven and Bull hills, recently shipped two carloads of ore that assayed about $35 per ton.——Lessees operating in the American Eagles shipped 12 cars of ore during September which assayed $34 to $194 per ton and averaged $55, the total amounting to approximately $16,000.——The output from the Cresson property during September was 2500 tons of $25 ore.——In the suit over apex rights brought by the Work Mining & Milling Co. against the Doctor-Jack Pot, the decision has been rendered in favor of the latter.——F. L. Smale and associates have secured an 18-months lease on the east half of the Last Dollar property.——G. E. Copeland, of Victor, has opened a 30-ft. vein on the 350-ft. level of the Montrose mine and is shipping 30 tons of hand-sorted ore per day which averages $25 per ton.——The compressor plant at the Ophelia was burned October 10 and pipe-lines are being laid from the Callie and Little Clara mines.

IDAHO

IDAHO COUNTY

The machinery for Grangeville mine which was recently taken over by Portland operators has arrived in Elk City, and is being forwarded to the mine. The equipment consists of a Joshua Hendy hoist, 500-ft. capacity, Knowles sinking pump, Ingersoll-Rand compressor and drills, and five 1500-lb. stamps. It is expected to have the plant in operation within the next month. Underground the shoot has been proved to be about 300 ft. long and 8 ft. wide. S. J. Fore is manager.——Adit No. 2 on the American Eagle ground about 200 ft. from the present stopes has opened the shoot which assays $17 per ton at that point.——The cross-cut on the Gold Bug group in the Tenmile district has opened a shoot of free-milling ore.

MISSOURI

JASPER COUNTY

(Special Correspondence).—In various parts of the district systematic prospecting is being carried on. In the extreme northern part near Neck City a number of drill-holes have been sunk on the Weaver farm and a good discovery of zincblende reported. Five out of seven holes are in pay-ore, the mineral ranging from 158 to 175 ft. in depth.——Activities have been revived in the old South Carthage mines which were rich silicate producers about ten years ago. The burning of the Central pumping plant stopped operations there, the ground being flooded and left untouched since that time. Mallory & Co. have recently prospected on the old Kiheka lease and found lead three feet below the surface. At 16 ft. silicate was struck and continued to 25 ft. The silicate ore here is particularly high grade and efforts are to be made at once to open these rich old producers as it is known that the ground is still rich in ore.——Another old camp which is active after an idle period is the Lehigh field. The United Zinc Co. has bought large leases just north of the camp and has done considerable prospecting. The results of the efforts have been carefully kept secret but it is known that some excellent discoveries have been made and the ground will be further opened. The company has made a number of sub-leases and several derricks are going up. Hand-jigs are used for the present.——Another discovery of importance was made recently by a Joplin company on an abandoned lease of the Granby company on Smelter hill. A number of companies worked this land and four shafts are down but the success was indifferent.——The Oronogo Circle Co. has just made a rich find of 'Steel Jack' in the roof of a drift at 230 ft.——Many companies are hastening the completion of their milling plants during favorable weather. Among the companies building is the Empire Zinc Co. which is erecting a large 350-ton mill in the disseminated zinc belt west of Joplin. The ore is an extension of the deposits of the Sampson and Muskingum mines. The tract worked by the Empire company is the old Miles land and previous to the erection of the mill systematic drilling was carried on around an old shaft.——Another new plant will be added to the west Joplin camp by the erection of the 400-ton mill by the Falls company on the former Black Cat lease. Following the removal of the former mill the present company began a thorough prospecting with the sinking of three shafts and driving two connecting drifts ——In the Webb City camp several new plants are being built. On the Centre Creek land the Prudential company is building a 200-ton mill on a sub-lease from E. Tyree. Three shafts have been put down disclosing ore in sheet formation at 190 feet.

Joplin, October 15.

NEVADA

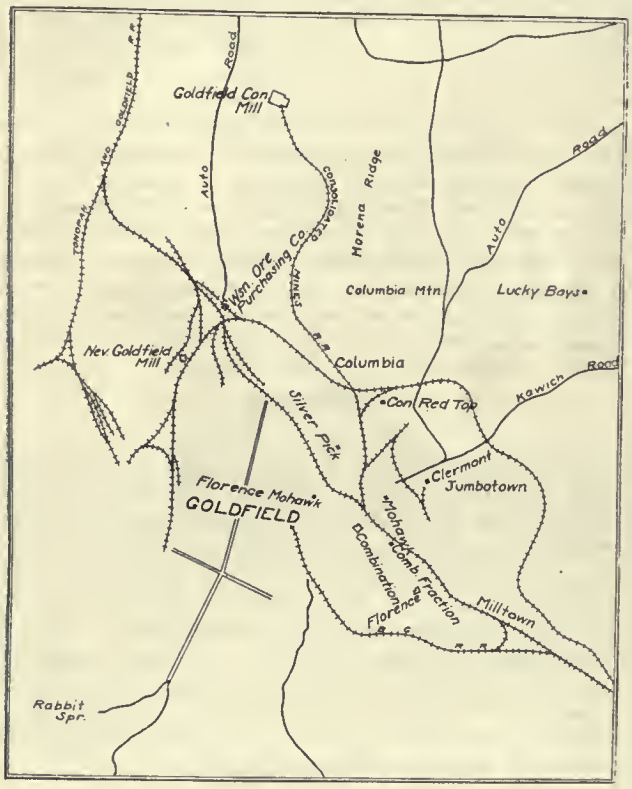
CHURCHILL COUNTY

The Nevada United Mining Co., operating at Copper Reid camp, High Cloud district, thirty-five miles southeast from Lovelock, has driven a 3050-ft. cross-cut, gaining a depth of 1000 ft. from the highest surface point. A lode of zinc-bearing ore was intersected at 1300 ft. from the portal, this ore assaying about 8% zincblende. The last 250 ft. of the cross-cut passed through lode material; 25 ft. of this is ore assaying 2½% copper; then 35 ft. of leached gangue; beyond this is 90 ft. of massive pyrite ore. John T. Reid, manager for the company, under whose direction all the work has been done, counts on being able to supply a big tonnage of iron ore required as a flux, as well as a good tonnage of copper and zinc ore. However, the company is not yet ready to ship ore. About 700,000 gallons of water per day is flowing from the cross-cut. The company has spent about $220,000 on development and equipment.

ESMERALDA COUNTY

(Special Correspondence).—The Goldfield Consolidated Mines Co. shipped to the smelters in September 123 tons of ore valued at $748.45 per ton, or a total of $92,060. This ore was taken chiefly from the new workings on the 1000-ft. level of the Clermont mine, where the average value of the product from new drifts was 2.26 oz. gold per ton. The drift has followed the vein for over 100 ft., but after being in ore of excellent grade for 35 ft. the quality showed a material depreciation although the management is still encouraged with the showing and it is believed that with the present developments alone the discovery is a most important one. In character this ore more nearly resembles that of the main Mohawk ore-shoots than it does the ore of the vein first opened on the 1000-ft. level of the Clermont, farther to the north and east, and contains seams of the typical Mohawk ore, with the characteristic breccia, talc, and splashes of telluride. The best grade of ore continues to come from the Clermont, that most nearly approaching the new orebody on the 1000-ft. level having been taken from the 600-ft. level.——The Florence Goldfield company is treating 150 tons per day, shipping concentrate. It is said that a satisfactory profit has been realized from a comparatively low-grade product but that the mill heads have advanced of late owing to the im-

proved quality of the ore coming from the stopes opened in the northern vein on the 350-ft. level and followed for a considerable distance to the south from the territory of the old Reilly lease. Laterals will be driven on the 600-ft. level to explore territory that has been highly productive above the 500, particularly on the main Florence, the Engineers, and the Little-Florence veins. One of the strongest ore-shoots of the Florence was developed by a winze 60 ft. below the 500-ft. level on the Rogers lease, adjoining the Little-Florence and at the southern extremity of the Florence hill, but the heavy flow of water prevented extensive work at this point to which a drift will be driven as soon as practicable on the 600-ft. level.——At its leased mill the Combination Fraction company is treating 50 tons per day with a satisfactory recovery of gold. The annual report of this company is awaited with interest, but it is not thought probable that a dividend will be declared at this time as the company has been under heavy



Goldfield District.

expense for development and mill repairs and although the treasury is known to be in a prosperous condition the relatively small amount of ore treated in late months, owing to water shortage, must of necessity have curtailed the company's earnings to a considerable degree.——By a recent decision of the District Court in the case involving the Diamondfield Black Butte Reorganized Mining Co. it was determined that the treasury stock held by the Registration Trust Co., as trustees for the mining company, had been illegally voted at the stockholders' meeting and that the Patrick faction had been duly elected directors of the company. The Manning contingent has not announced whether or not it will take an appeal to the Supreme Court, but L. L. Patrick and his associates will proceed to endeavor to raise funds for the development of the claims which have already yielded about a quarter of a million in shipping ore and have a large tonnage of excellent milling ore exposed on dumps and in the workings. Lessees are still making occasional shipments of rich ore from near the surface.——Development on the Yellow Tiger continues on the 700-ft. level and water difficulties have been eliminated at this depth.——Two shipments of $50 ore have been made from the Nevada Eagle, three miles west of town, and there is a good showing of ore in the raise above the 250-ft. level.——The Grizzly Bear Mining Co., operating a lease on Consolidated ground, has been idle with the exception of keeping water out of the 1200-ft. shaft, the deepest in the district. It is possible that operations may be abandoned as the Consolidated has refused to extend the lease, which expires February 1, 1911. Only low-grade ore has been found in driving at a depth of 1170 ft. The project was backed by Parisian bankers.

Goldfield, October 15.

HUMBOLDT COUNTY

The Crawford Leasing Co., in which C. P. Crawford and others of Salt Lake City are interested, has taken a 2-years lease on the Mayflower group of claims in National camp, and will proceed with development. Mr. Crawford spent two weeks in the district this month.

NYE COUNTY

(Special Correspondence).—John B. Barker, J. P. Burns, and P. Chandler have secured a two-years lease on the Capricorn property on the east slope of the Funeral range about sixteen miles from Rhyolite. This property has yielded in the past several shipments of rich silver ore, mainly in the form of chloride.——The Keane Wonder management has purchased a Sullivan compressor and several machine-drills, and is installing a 75-hp. engine to operate them. An addition of 20 stamps and cyanide plant is to be built at the mill and it is probable that the line of the Nevada-California Power Co. will be extended to the mine, the steam plant being retained as a reserve.——The lessees on the Diamond Bullfrog on the east slope of Ladd mountain are getting better results than any of the lessees who have operated in the Rhyolite district for some time. They have shipped several carloads of ore that have yielded over $50 per ton. The property is opened by a 400-ft. shaft and over 600 ft. of driving has been done. The last carload of ore was shipped to the Eclipse mill which is being fitted with an automatic sampler for custom work.

Rhyolite, October 15.

(Special Correspondence).—The Sand Grass shaft of the Tonopah Mining Co. has been sunk to a depth of 525 ft. and is still in the later andesite. In the last week in September the desert mill of the Tonopah Mining Co. dropped continuously 99 of the 100 stamps, crushing 3550 tons of $20 ore.——Work at the new surface plant of the Tonopah Belmont at the Belmont shaft is proceeding slowly, due to the tardy arrival of machinery and structural iron. The east drift on the 1100-ft. level has passed through the faulted zone and is again in the earlier andesite. The work of sinking the shaft from the 1100-ft. level to the 1200-ft. has been resumed.——The Tonopah Extension is making rapid progress on the south foot-wall cross-cuts from the main west drifts of the 500 and 600-ft. levels. These cross-cuts are to prospect the 3-ft. vein of high-grade milling ore that a similar cross-cut on the 400-ft. level opened recently.——The MacNamara reports a new discovery of high-grade shipping ore on the 300-ft. level. From one to two feet of this vein is being sacked underground.——In the West End two new raises to the west on the 400-ft. level have cut the main vein and stoping will begin shortly. ——The new discovery fifteen miles east of Tonopah has been bonded to George Wingfield for $2000 in cash and $100,000 within six months. The value of the property now is merely guess work as the deepest work is a 15-ft. hole.

Tonopah, October 14.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The main shaft of the Deadwood mine in the Mogollon district was sunk 12 ft. during the week and has reached a depth of 480 ft. The framework for the mill is nearing completion and the machinery for the plant is being delivered, some of the heavier parts having arrived within the past few days.——The concrete dam at the intake of the pipe-line being laid by the Ernestine Mining Co. has been finished and all the trenching with the exception of some rock work has been completed. The 4-in. pipe for the line has been delivered and a large crew of men is busy on the line.——The production at the Socorro mine is approaching 150 tons per day and

it is probable that this will be increased in a short time.——Preparations are being made to resume work at the Trilby group.——Considerable new machinery, including a hoist and pump, has been ordered by the Mogollon Gold & Copper Co. to facilitate the work at the Cooney group.

Mogollon, October 15.

UTAH

BEAVER COUNTY

(Special Correspondence).—The Utah Mining, Milling & Transportation Co., made up of Boston stockholders, has large holdings lying south of the Moscow, usually referred to as the Hub and Lady Bryan groups. Considerable development has been done at two shafts which are 1600 ft. apart. The new shaft, which is the one farthest southwest, is to be the centre of operations. The small gasoline hoist and air-compressor are being replaced by similar machines of greater capacity. This shaft has a depth of 300 ft. A cross-cut has been driven from the 200-ft. station a distance of 150 ft. to an orebody on an east-west vein. There has been 100 ft. of driving and some cross-cutting which show the vein to be 30 ft. wide, the ore from which contains about 50% iron, with lead carbonate and silver. The dip of the vein is toward the shaft; hence, to open the orebody from the 300-ft. station will require a much shorter cross-cut than the one at the 200. High-grade red oxide of copper has been found in a bedded vein in the limestone, the planes of which are cut by the lead-bearing fissure. Shipments of lead-iron ore have thus far amounted to eight or nine cars, and two cars of copper ore have been shipped. It is said the cuprite shipments assayed 10 to 12% copper. John Thomson is in charge of the work, and C. T. Birchard, of Boston, president of the company, was recently at the property. The ore has to stand a wagon haul of seven miles to Lahoe station. The Commonwealth is opened by a 1400-ft. adit which takes a westerly course through a limestone country. Extensive development from this adit as a base has resulted in opening several east-west fissures and a number of north-south veins which occur in the bedding planes of the lime. The driving from the adit on the bedded veins has resulted in opening the east-west fissures. The bedded veins are mostly a copper ore, while lead seems to predominate in the fissures. However, this rule is subject to a good deal of variation. Three of the bedded veins have been opened, each of them having a dip east of 45°. On one of the east-west fissures is a 125-ft. incline winze, which follows the pitch of the oreshoot. Many high-grade samples of lead and copper ore have been taken out, but no general averages are obtainable. The property is equipped with a gasoline engine which drives an air-compressor. R. B. Kenyon is superintendent, the president of the company being N. A. Dunyon, a mining engineer of Salt Lake.——The Western Pumping Association, comprising most of the mine operators of the Star district, has installed a pumping plant in the valley, from which a supply of water is pumped to practically all the mines of the district.——The South Utah Mines & Smelters is the name of the corporation which now controls and operates the Cactus mine and concentrating plant at Newhouse, with E. H. Lundquist as manager. After an inactive period of a year operations were resumed within the last six weeks, with over 200 men on the payroll. It is proposed to mine and concentrate about 800 tons of ore per day, though as yet only 500 to 600 tons are being handled. The concentrate product is being shipped to the International smelting plant at Tooele. The ore consists mainly of chalcopyrite in a monzonite gangue. After passing through a crusher at the mine the ore is hauled to the mill-bins in cars that travel on a standard-gauge track. At the mill it is first sized by 16 m.m. trommels, the oversize of which is reduced to pass 16 m.m by a Gates gyratory crusher. The 16 m.m. undersize is passed successively to 9, 5, 2½, 1½, and ¾ m.m. trommels; the ¾-m.m. undersize going to hydraulic classifiers. All sizes from 9 to ¾ m.m. are jigged, and those from ¾ m.m. to slime treated on tables. The table feed consisting of the undersize of the ¾-m.m. trommels passes through the hydraulic classifiers; the overflow from the latter goes to Callow tanks, the thickened pulp of which passes to vanners. All the tailing from the 9 to 5-m.m. jigs are re-crushed in the fine rolls; and those between 2½ and ¾ m.m. are reground in Huntington mills, the product of which is elevated to ¾-m.m. trommels, whose oversize goes to jigs and the undersize to hydraulic classifiers. The table middlings are re-treated on middling tables. The jigs handle all from 16 to ¾ m.m. The undersize of ¾-m.m. screens, except slime, goes to the tables, the slime being handled by Johnston vanners. All table tailing and vanner tailing pass to waste dumps. The mill is operated by electric power derived from the power plant at Beaver. E. E. Meyer is engineer at the mine; R. Madson is mine superintendent; R. W. Bruner is mill superintendent. The buildings and accommodations for workmen, including club-houses and reading-rooms, are among the best of all the mines in the State.——The Harrington-Hickory property of the Majestic Copper Co., is undergoing further development, under direction of A. D. Moffet. The ore here consists largely of lead and silver, with some copper. The main shaft is 600 ft. deep. At present driving is in progress from the 600-ft. station to cut under the orebody which is opened by the 500-ft. level. As is characteristic of the Star district the veins of the Harrington-Hickory consist of fissures, and of orebodies in the limestone closely associated with the fissures.——The Utah-United Mines Co., whose property lies north of the Old Hickory, is sinking its shaft below the 385-ft. point, and the plan is to sink to the depth of 500 ft. and establish a level there. On the 360-ft. level many varieties of copper ore were found. A. J. McMullen has been directing the affairs of this company for several years.

Milford, October 15.

JUAB COUNTY

A new gasoline-driven air-compressor has been installed at the claims of the Tintic Mines Co. in North Tintic as the workings have reached ground in which hand drilling is not economical. The shaft is down over 250 ft.——The installation of new pumps at the Centennial Eureka has been completed and one unit placed in operation. This is handling over 400 gal. of water per minute so there will be no need starting the second unit till wet weather sets in.——The connection between the raise from the 1000-ft. level and the shaft has been made with good results, the alignment being almost perfect.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—At the Spokane State fair the West Kootenay ore exhibit won the interstate trophy, while the Ainsworth display won the district cup.——Ore shipments from the Big Bump mine of the Salmon River Mining & Milling Co. will begin within a week or ten days. There is nearly $300,000 worth of ore blocked out in the property. It is the present intention of the company to erect a 20-stamp mill probably in the spring. The mill will be built near the company's mine at Erie.——A German syndicate has bonded a group of 12 claims in the Sheep Creek district through Alvo von Alvensleben of Vancouver.—G. G. S. Lindsey, at one time president of the Crows Nest Pass Coal Co., has examined the mines of the Sheep Creek district and is taking data and a number of samples of ore east with him, which may result in capitalists being introduced to the district.——Two feet of ore has been uncovered on the Tiger property at Ainsworth assaying 30 oz. silver and 75% lead. A small force is at work on the new find.——The Geological Survey of Canada will issue a geological and topographical map of the Lardeau and Phoenix districts this winter, the culmination of several seasons field-work.——A conference is being held at Victoria between Premier McBride, L. C. Gillowan, and Louis Hill, of the Great Northern Railway Co., at the termination of which it is hoped that arrangements will have been perfected for the reopening of the Kaslo and Slocan railway recently damaged by fires.

Rossland, October 15.

Universities and Mining Schools

H. D. Pallister, M.E., of the Case School of Applied Science, formerly mining engineer with the Chisos Mining Co., Terlingua, Texas, and later instructor in mathematics at the Chase School, has been appointed instructor in metallurgy at the School of Mines, Pennsylvania State College, and Victor Ziegler, B.A., of Iowa University and M.A. of Columbia, instructor in geology and mineralogy.

A number of changes in the faculty of the College of Engineering at the University of Wisconsin have marked the opening of the college year. One of the important additions to the faculty is F. W. Doolittle, who succeeds C. H. Burnside as Assistant Professor of Mechanics. Mr. Doolittle holds the degree of Bachelor of Arts from Princeton and Civil Engineer from the University of Colorado. Mr. Burnside has resigned to accept a position at Columbia. J. C. Steen, for a number of years superintendent of the machine shops, has resigned and will be succeeded by A. L. Goddard, M.E., '96, Wisconsin.

J. A. Holmes, head of the United States Bureau of Mines, addressed the students of the College of Mines of the University of California, and on the evening of October 19 he spoke to the association which is studying the problem of disposition of sulphur dioxide formed in copper smelting. Mr. Holmes spoke of the problems to be studied and emphasized the fact that the Bureau would endeavor only to undertake work which is beyond the scope of a single company, both in the conservation of life and natural resources, and in improvement of metallurgical processes. He stated that a number of cars were to be sent to the various coal-mining districts equipped with men and apparatus to demonstrate mine-rescue methods and first aid to the injured. The work of testing various explosives and experimenting with coal dust will be continued at the Bureau's headquarters in Pittsburg.

The Ohio State University at Columbus has issued Bulletin No. 32, Volume XIV, a commemorative bulletin, descriptive of the Department of Civil Engineering. It was intended to publish this brochure nearly two years ago upon the thirty-fifth anniversary of the founding of the department, but a number of causes prevented the work being completed at that time. It reviews the history of the University and gives short sketches of the past and present instructors. Especial emphasis is laid on the prac- summer school work and a number of half-tones show -ative views of the students during this portion of equipment used. A list of the alumni, expense for development attendants is given and the out- treasury is known to be- -argement of the department to meet atively small amount of co- institution. Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

LEASE OF MINE

The lessee of a coal mine bound himself by the lease to operate the mine in the usual or practical way of mining, to build a tip house and make such other improvements as would be necessary in the operation of the mine to pay the lessor a royalty of 10c. per ton on all the coal mined The lessor, a corporation owning a general store, agreed to sell the lessee and his employees all goods and supplies at the same price charged its own miners. It also agreed to furnish the lessee a sufficient number of cars to handle the output of the mines. The lessee entered upon the operation of the mine and before the expiration of the first year had become indebted to the lessor in a large sum in excess of what the mine yielded. Thereupon the parties entered into a new contract, whereby the lessee was to pay the lessor out of the sale of the coal from the mine $100 per month until such excessive indebtedness had been paid in full. It was also provided that if any one of said payments should become due and unpaid the lessee would surrender to the lessor certain property used in operating the mine, unless such default was occasioned by a strike. The contract also provided that in the event of failure of the lessee to make such payments, he thereby sold, granted, bargained, and conveyed all his property to the lessor for the sum and amount of such indebtedness, and in such event the original lease was to be null and void. Some time after the execution of this new contract default was made in the payment of the monthly installments and the lessor took possession of the mine and of the lessee's property and refused to permit him to operate the mine. Thereupon the lessee brought an action for a cancellation or reformation of the last contract on the ground of fraud and for damages for depriving him of the possession of the mine. The lessor admitted that such contract was obtained by fraud and that the lessee himself was a party thereto and not in position to demand equitable relief. The evidence showed that the second agreement was prepared by the president of the corporation, the lessor; that the lessee was uneducated and unable to understand the contract; that the president told him at the time that it must be executed to show the settlement of the amount due; that the lessor had a lien on the lessee's property to secure its payment and that it in no way affected the original contract or lease. It appeared also that the president wanted to and did use the second contract for the purpose of inducing third persons to purchase his stock in the corporation because of the unprofitableness of the mine and the mining business, and that he did thereafter show the contract to such third persons and sold his stock to them. It was accordingly decided that the lessee was not a party to the fraud, that he was entitled to a reformation of the contract and to a return of his property and the possession of the mine, and that the lessor was only entitled to a lien on such property for the amount due, enforcible only after the expiration of the lease. But the lessee was entitled to no more than nominal damages because it appeared that the mines had been operated at an actual loss.

Phenix-Jellico Coal Co. *v.* Grant, (Ky.) 125 Southwest. 165, Feb. '10.

COMPETENCY OF MINE BOSS AS AN EXPERT WITNESS

Where a mine boss testified as expert witness on behalf of owner and operator, and had, in answer to questions, qualified himself to speak as expert in an action for injuries from falling rock in the mine, it was competent to show that such boss had been three times tried and convicted for neglect of duty as mine boss, to develop facts tending to rebut the conclusion of expert competency.

Princeton Coal Mining Co. *v.* Howell, (Ind.) 92 Northeast. 122, June '10.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JEROME B. LANDFIELD is in San Francisco.

CLAUDE T. RICE has been in San Francisco.

W. C. MENDENHALL has been in San Francisco.

EDGAR RICKARD has sailed from New York for London.

HOWARD D. SMITH was in St. Louis on his way to New York.

JOHN A. RUNNER, mining engineer, is in Lovelock, Nevada.

J. A. HOLMES and H. FOSTER BAIN visited Coram, California, Tuesday last.

S. E. BRETHERTON is in Plumas county, California, on professional business.

CHARLES B. E. DOUGLAS has left San Francisco for Bolaños, Jalisco, Mexico.

J. P. KEENE has returned to Woodland, California, from a trip to British Columbia.

GELASIO CAETANI left on the *San Juan* October 15 for Nicaragua for a three-months trip.

E. F. BURCHARD is on his return trip to Washington, D. C., from an extended tour through the West.

GEORGE W. PAYMAL, of San Francisco, is spending some time in the vicinity of Winnemucca, Nevada.

J. B. FLEMING is at Fairview, Nevada, to design and direct the construction of the Nevada Hills mine.

WILBUR H. GRANT is working on the geological survey of the Santa Eulalia properties in Chihuahua, Mexico.

D'ARCY WEATHERBE will spend the winter at the Kolchan mines in East Siberia preparing for dredging next season.

E. V. DAVELER, superintendent of the Phoenix mine at Sierra City, has been in San Francisco on professional business.

HENRY HAY has accepted a position with the Engineering Department of the Consolidated Gold Fields of South Africa, Ltd., at London, E. C.

JOHN COOPER has resigned as mine superintendent of the Mexico Mines of El Oro in order to further his railroad interests in the State of Zacatecas.

E. HARMS, superintendent of the Torreon smelter, Torreon, Mexico, is on a trip for a month through Colorado, Utah, and Montana, visiting smelters and mines.

CARL SCHOLZ is in Europe to purchase apparatus for equipping the Illinois Mine Rescue Stations and to make investigations for the United States Bureau of Mines.

SUMNER S. SMITH has accepted a position as mining engineer with the United States Bureau of Mines and will leave San Francisco for Pittsburg, Pennsylvania, October 24.

ARTHUR LAKES and ARTHUR LAKES, JR., have removed their offices to 701 Gas & Electric building, Denver, where they will continue their practice as mining and metallurgical engineers.

ELI T. CONNER has opened a temporary office at 516 Traler's National Bank building, Scranton, Pennsylvania, in order to properly care for important professional engagements in the Lackawanna and Wyoming regions of Pennsylvania. His office in the Real Estate Trust building, in Philadelphia, will be open as usual.

C. H. SHAMEL, of Seattle, Washington, sailed on October 11 from San Francisco for the Philippine Islands. He will spend four months investigating the mining, geological, and agricultural features of these islands. Afterward, he will spend some time in China and make brief stops at the Malay Peninsula, Ceylon, and Hindustan, returning by way of Europe. He will return to Seattle in the fall of 1911, and resume his practice of law and his work in the law department of the University of Washington. While in the Philippines his address will be care of Elk's Club, Manila, Philippine Islands.

HANDLING GRAVEL ON THE PUGET SOUND

The demand for gravel for use on the highways, as well as for concrete is daily increasing everywhere. Along the Pacific Coast the gravel is obtained from large pits on the shore of Puget Sound, about 30 miles by water from Seattle. The barges are loaded, towed by tugs and delivered alongside a pier at Seattle. A simple, although unique system, has been intalled by the Richmond Beach Sand & Gravel Co., of that city, for unloading the gravel from the barges to elevated storage bunkers, from which wagons are loaded by gravity, as well as railroad cars for transporting gravel to other points. The elevated bunkers are constructed on pile footings at the head of a narrow slip on the water front.

Fig. 1. Gravel Bunkers at Seattle.

The first illustration shows a recent view of these bunkers. Along both sides of this narrow neck of land are large warehouses on wharves extending out to the harbor line. Between each wharf and the slip is a pile trestle carrying a railroad track, and these tracks connect at the shore end of the slip with the main line of the Great Northern and Northern Pacific railroads. The gravel barges are unloaded with the use of a clam-shell bucket swung from a stiff-leg derrick mounted on a trestle over one of the railroad tracks, the gravel discharging into a Jeffrey receiving hopper elevated at the end of the bunkers, or directly to cars on either track. Nearly all of the gravel, however, is delivered to the storage bunkers for local distribution in wagons. The derrick is operated by a double-drum hoist geared to a single-phase, alternating-current, variable speed, 60-hp. motor. The bunkers are 20 by 120 ft. and provide a storage capacity of over 1000 cu. yd. They are divided into 24 bins thus enabling the various sizes of gravel to be handled independently. The gravel passes from the receiving hopper through a distributing plate feeder, which is also constructed to deliver sand to a Jeffrey steel drop-pan conveyor, which extends over the entire length of the bin on the longitudinal centre line of the latter. A roof is provided which covers the bins and conveyor line. The conveyor line is 130 ft. between centres, traveling at 70 ft. per minute, geared to a single-phase, alternating-current, continuous-speed motor. Each pan section of the conveyor is 18 in. wide, 24 in. long, and 6 in. high carried on two axles supported by two pairs of flanged wheels placed at the ends of every pan and traveling on a pair of rails on a frame spanning the bins. (See Fig. 2.) Only one of the axles extends to the chain, allowing the pan to pivot freely, between the two strands of chain. The rails are in sections hinged over each bin so that any section may be swung out of the way. This conveyor is so designed that when each pan reaches a delivery point where a section of trackage has been taken out, the rear end of the pan automatically drops down and the load is discharged into the bin below. As the conveyor proceeds, the pan returns; the separate pieces of track swing back, in no way interfering with the movement of the conveyor. The floors of the bins are sloped to a row of outlet chutes along both sides. A roadway is built around the bunkers at the level of the street in front of the slip that wagons approaching and leaving may not interfere. The chutes are set to deliver into the wagons and are each controlled by a gate operated from the latter. Barges loaded with gravel are delivered to the plant as frequently as the market demands. The gravel is unloaded from them at the rate of 100 tons per hour and the supply drawn from the bunkers as required. Under normal conditions, the derrick will deliver from the barges to the elevated hopper at a rate of 60 cu. yd. per hour. The Jeffrey conveying system was designed to handle the gravel as rapidly as it flows from the hopper, its rated capacity being 80 cu. yd. per hour.

TABLE OF CONTENTS

EDITORIAL

FREIGHT congestion is already beginning to demoralize traffic. On the Baltimore & Ohio Southwestern there has been a virtual blockade. Severe shortage in the Chicago and dependent coal markets is anticipated this winter, since far less than the normal amount of coal has been moved during the summer.

ALASKA and the Morgan-Guggenheim syndicate are so much in the public eye that we take special pleasure in presenting this week pictures of the famous Bonanza copper mine and of the Copper River & North-Western railroad. Fortunately the controversy that has waged over coal matters has not involved the copper mine, and construction on a large scale has gone steadily forward. Such substantial work as is being done in the Copper River country deserves, as we hope it may achieve, success of a commensurate order.

ABANDONMENT of the Braceville, Illinois, mine is one of the penalties resulting from the long-continued strike and the methods used by the men in fighting. The engineers and firemen having been withdrawn, it is now found unprofitable to attempt to recover the mine. The Braceville was the largest mine in Grundy county, shipping 221,504 tons of coal in 1909. The Braceville Coal Company employed 430 men and was an old and successful corporation. The mine itself probably would have been closed shortly in any event, as the ground was nearly worked out, but the loss from its premature abandonment must be charged to the waste involved in our present methods of fighting and settling labor disputes.

DIRECT smelting of ore assaying 2.62 per cent only of copper, and gold and silver to a total value of less than a dollar per ton, is being regularly carried on at the works of the Balaklala Consolidated Copper Company in Shasta county, California. When account is taken of the situation of the mine, the necessity of bringing in coke from China, Germany, or some point from which charges are equally great, and the fact that the project was organized at a time when copper sold at a price much above that which has obtained since the plant was open, great credit is due Mr. R. T. White, the manager, and his associates. That so small and heavily handicapped an enterprise should expend the money necessary to develop on a large working scale the Cottrell process of fume precipitation, speaks well for the professional standards of the men in charge. Their success will leave others much in their debt.

ANNEXATION of Korea by Japan has materially changed conditions in certain particulars. The extra-territorial rights of foreigners naturally have disappeared. Old concessions and enterprises undoubtedly will remain undisturbed; indeed since the Japanese have been in Korea they have afforded established enterprises every reasonable facility in the way of additional concessions of forest, rights of way, and other things legitimately necessary to success. In Japan proper, as is well known, foreigners cannot own land and foreign companies are not given concessions to mines. Just how this rule will be applied in Chosen, as Korea is now to be called, has not been made clear. That foreign capital will be given some opportunities is probable, but until the terms are made known, promotion is at a standstill.

EXTENSIVE mine development for some particular metal is sometimes surprising if not always disappointing in its results, as, for instance, the effort of a miner in the Black Hills of South Dakota who industriously prospected his claim for wolframite which he failed to find, though he did discover gold in surprising amount, taking out over $70,000 in a few weeks. In California work has been done to develop copper ore which found little copper, but did discover a great deal of zinc sulphide, though nothing has since been done to develop it. Other similar instances might be cited which tend to show that prospectors do not always find what they expect, and that they frequently fail to take advantage of and turn to the best use the discoveries they do make.

SIBERIA and its placer mines are like to attract more and more attention. The Northeastern Siberian Company, Ltd., has been one of the most discussed enterprises in that country. Its whole career has emphasized the need of better understanding between the Russians and those, Americans and others, who would take part in development of Siberian mines. The story of the 'confiscation' of gold by one of the officials has been frequently repeated, and it is a pleasure to present this week Mr. John Rosene's statement completely exonerating the Russian officials of any blame in the matter. Better acquaintance will prevent such misunderstandings. Siberia needs the American and English engineers and financiers who are disposed to undertake mining there and we, for our part, need perhaps more patience and less suspicion of those whose ways are not as ours.

PHILIPPINE dredging fields have heretofore been worked almost entirely by small native and New Zealand dredges. This is not surprising when account is taken of the limited amount of definite knowledge of the extent and richness of the ground, the exposed position of many of the dredging sites at Paracale, and the relatively small amount of capital locally available for investment. New Zealand dredges are much smaller and less expensive as to first cost than are those of the California type. They have been erected on such terms that the machine could be paid for from the returns, in other words, the manufacturers have found the capital, and under these conditions they naturally have done the pioneer work in the Philippines. There is undoubtedly a legitimate field for their permanent operation and many and more accurate data are needed as to their ultimate economy. In the columns of our London contemporary, *The Mining Magazine*, a discussion of the relative efficiency and economy of dredges of the California and New Zealand type, has raged for some months. It is now announced that the Philippine Exploration Company is to buy an American dredge. This, with the one starting next year at the Kolchan mines in Siberia, and another to be erected in Burma, should give additional data on the operation of California dredges under foreign conditions.

CHINA and its future have been much in the public mind recently, but apparently it would be well to take into account more of China at the present. Last April we had the pleasure of publishing an account of the Tayeh iron mine written by Mr. A. J. Stetzer, and in this issue we present an account of the Pinghsiang Colliery which, with the Tayeh mine, furnishes the raw material for the steel works at Hankow. The account is written by Mr. Karl P. Swensen, one of the young Americans who are, as teachers in mining schools, assisting our neighbors to an early conquest of their great natural resources. The account of these works has especial interest to the Pacific Coast States of America, since a considerable part of the pig iron used in Western manufacturing comes from these far away furnaces. Incidentally, much coke is also imported from there, since when loading a ship with pig iron there would be much vacant cargo space unless a lighter material were also shipped. The coke used to reduce Shasta County copper ore comes in part from Hankow. Recently the Chinese Engineering & Mining Company, Ltd., has arranged to enter the San Francisco market with coal so that northern as well as southern China is now sending fuel to our Western States.

SOUND common sense characterized the address of Mr. E. H. Gary, delivered before the American Iron & Steel Institute at Chicago recently. He pointed out that great progress has been made in this country during the last decade in the direction of improving the methods and morals of men. There has been, from time to time, reason to criticise the conduct of individuals connected with the management of large affairs, and the dividing line between right and wrong, between honesty and dishonesty, must be more definitely pointed out. The dishonest people in all departments must be driven from all positions of power and influence. It is not so important to consider the merits or methods of the individuals who have been prominent in the crusade for the betterment of conditions, indeed the criticisms themselves have not always been well founded, but they have resulted in benefit, and it is time for everyone to take a decided stand in favor of right conduct in matters concerning the great economic questions which involve the life, health, safety, and happiness of the whole people. In all this Mr. Gary has voiced the real sentiments of sober-thinking Americans.

Essentially his message is the same that Mr. Roosevelt has been delivering, and it would be well to note that the head of our largest business enterprise, and our most astute politician, to give Mr. Roosevelt no higher title, are together in this. Holders of 'undigested securities' must not mistake effect for cause. The public has stopped buying not so much because of 'threatened legislation hostile to corporations' as because dishonesty in high places has shown the need for regulative measures to make investment safe.

Mine Rescue Cars

An interesting feature of the campaign against mine accidents that will be waged this year in the United States, will be the use of mine-rescue cars. The Illinois Commission has ordered three and the United States Bureau of Mines six, of which the first has just been delivered and started west. The cars are re-constructed Pullman sleepers, courteously furnished at nominal cost by the Pullman Company, which has shown great interest in the work. Aside from living quarters for the men, shower baths, and office facilities, there will be a gas-tight chamber in which men may be trained under working conditions in the use of rescue apparatus. It is proposed that each car shall work in a limited district, being at all times subject to call in case of accident. Between times the car is to travel from mine to mine, stopping a week or more at each to train a crew of local miners. This plan of taking the instruction to the men rather than of attempting to get the men to come to fixed stations, will, it is thought, operate to more quickly educate a large body of men in the new methods and tactics. At the same time the engineer in charge of each car will become personally familiar with the mines in his district and will thus be prepared to act intelligently in assisting the local and company officers in case of a disaster. In addition to the mining engineer, the mine rescue foreman, and the cook, each car will carry a man thoroughly familiar with the methods of first aid work, and instruction along this line will be offered. The men for this work have been selected from among members of the excellent first-aid corps that have done so much to improve conditions in the anthracite mines. It is hoped that similar corps can be organized in the bituminous districts. Incidentally the engineer in charge of the car will be prepared to give lectures on explosives and other subjects closely related to the regular work of the miners, and by every means possible the attempt will be made to educate all concerned in the mining industry to greater care, to the end that the mines may become safer. Eventually the States and operating companies must assume the burden of this work, but temporarily, and as an educational measure, the United States Government is assisting. The 'Seed Specials' of the agricultural stations are thus paralleled in the new mine-rescue cars, and just as the railways found a car the best medium for instructing their men in the use and care of air brakes, it is hoped that the new rescue cars will supplement, if they do not supplant, the mine-rescue stations. For the present the work will be mainly in the collieries, but when there is time and conditions are favorable the greater metal mining camps will also be visited.

Static Electricity in Ore Dressing

Electrostatic treatment of ore offers many interesting possibilities. So far attention has been concentrated mainly upon the separation of blende from pyrite. In the last six years a number of mills have been built to apply static electricity to treatment of these ores. While considerable tonnages were treated as early as 1905, principally with the Blake machines, on the whole the first attempts were not commercially successful. The difficulty seemed to lie in the generation and control of the current rather than in its application. At that time the approved method of producing static electricity was by use of a revolving mica plate such as ornamented class rooms and doctor's offices a generation ago. The current available was a function of the size of the plate that could be made to hold together while rapidly revolving. No method was known of driving these machines in series, though at the plant at Butte, Montana, where there were sixteen generators, the operator once succeeded for a few minutes in getting them synchronized. As this was accidental the feat could not be repeated. Insulation also afforded many difficulties, and it was found that the temperature and humidity of the air in the work room was of large importance. In Wisconsin, where one of the first mills was built and run, excellent concentrate could be made on some days, while on others, for reasons baffling explanation, no satisfactory separation could be effected. At Butte the attempt was made to keep the generators at constant temperature. At Salt Lake ore had to be run and re-run, until the profits ran away. Despite all these difficulties and failures, enough was learned to demonstrate conclusively that the method would be of large importance if only static electricity could be generated and controlled as were other electric currents. Experimental work was concentrated on this point and success has been attained. It is now possible to convert an ordinary alternating current into one having extremely high voltage and low amperage, which is essentially the static current. At Coram, in California, where Mr. F. G. Cottrell is working on precipitation of smelter fume with such a current, a voltage of 30,000 with a volume of a small fraction of one ampere, is regularly used. By means of ingenious devices the mere crest of each electric wave is picked off. In Boston, where the Huff Electrostatic Separator Company has been carrying on careful work for some years, other means of accomplishing similar results have been devised. In another column of this issue Mr. H. A. Wentworth, manager for this company, tells something of the range of applicability of the machines now perfected. At Platteville, Wisconsin, and near Salt Lake in Utah, they are already in use, and no one familiar with Western conditions doubts that their success means much, especially in the development of the zinc resources of the West.

The Pinghsiang Colliery

By K. P. Swensen

It is generally known that great progress is being made in the commercial and industrial development of China. The program of reform, as it is being carried on by the Chinese Government, calls for the Westernization, so to speak, of national affairs that will enrich the country and her people and put China on a par with other nations in trade relations. The upbuilding of modern industries is one phase of China's future growth, and what has already been accomplished is perhaps not yet fully realized by those who take only a casual interest in China. The future of China's financial condition depends to a large extent upon the development of the mineral resources, particularly the vast quantities of coal and iron that are known to exist. It may be stated concerning the actual condition of the development of the mineral industry in China, that small progress is being made except in certain coal and iron fields. This is due to the refusal on the part of the Imperial Government to grant mining concessions to foreigners. The strong feeling of distrust which is inherent in the Chinese character even toward each other, also bars them from seeking foreign engineering advice where Chinese capital is available for mining enterprises. The most striking instance of the presence of China's mineral resources and proof of the ability of the Chinese to develop them, is the Han-Yeh-Ping Coal & Iron Co., which comprises the Hanyang Steel & Iron Works, the Tayeh iron mines, and the Pinghsiang colliery, the three having been recently consolidated to form the above combination with a total capitalization of $20,000,000. This company is constantly increasing its equipment and output and can now turn out with its three modern blast-furnaces 500 tons of pig iron per day. Its steel plant consists of four open-hearth furnaces, one mixing furnace, cog mill, beam and angle mill, rail mill, plate mill, and other plants, capable of rolling about 1000 tons of finished product per day. This company is already making its competition felt in the American pig-iron market, while it supplies a large quantity of iron ore to Japan, as well as coal and coke to different parts of the Orient. The organization may well be considered as a nucleus around which industrial development and production will centre, and eventually make China a formidable competitor among the nations of the world. In the Province of Shansi alone, where considerable investigation has been carried on, it is estimated there are over 600,000,000,000 tons of coal, and in a single mine in the Pinghsiang district there is said to be tonnage enough to yield an annual supply of one million tons for the period of 200 years, with much more in prospect. When the number of high-grade orebodies now being developed is also considered, the great wealth of China as an iron and steel producer can begin to be appreciated.

The Pinghsiang colliery is situated in the Province of Kiangsi, close to the eastern border of the Province of Hunan. The locality has always been known to contain an immense quantity of coal, and the Chinese have been digging into these from the surface at points on the outcrops so far as their superstitions would permit. They used most of the coal thus obtained in the manufacture of coke. The mine is about 300 miles south of Hankow by way of the Yangste and Siang rivers to the port of Chu Chow; thence 60 miles eastward by railroad to Nganyuen. Pinghsiang is an ancient walled Chinese city about five miles distant from Nganyuen. The mine has an interesting history, and there was much trouble in getting started, because of its inaccessibility and difficulty in the movement of materials and supplies, and particularly because of the fact that the people of this part of the country, who are of a strong and fearless type and devoted to their traditions, were strongly anti-foreign and religiously opposed to the opening of any mines whatever in their country. In the face of many difficulties the mine started operations in the year 1898. There were strikes and revolts, and several times the foreign engineers were forced to flee. The last serious trouble took place in 1906. Order is now completely restored and the mine has been steadily improved in equipment, and its output constantly increased, until it ranks favorably with the best in the world. Too much praise cannot be accorded to the foreign engineers, who are all German, headed by Gustavus Leinung, for what they have accomplished in the building of this plant and the difficulties they have overcome. It is a pleasure to know that the foreigners in this mine have the confidence of the Chinese who are the owners and business managers, and further that these officials were even willing to borrow the sum of $3,000,000 from the Germans during the early life of the mine, with which to put it on a secure working basis. The loan was made ten years ago and it is now repaid, so that the Chinese are relieved of all obligation to the foreigner. It would be a great boon to China if more of its officials in control of mineral lands awaiting development would follow the example of this company in obtaining initial capital through foreign loans. The speedy development of China's immense mineral resources would be the result.

It is a surprise to a stranger to visit this mining camp. Riding over the railway from the Siang river to the mine, he is given a magnificent perspective of the typical Chinese landscape in a prosperous rice-growing section. From the mountain heights, irregular small ranges succeed each other into the valleys to blend with the foothills in a maze of terraced rice fields. One marvels at the thrift of the Chinese farmer and the intensive culture to which he is forced to resort. All this the traveler looks upon and wonders at the still crude methods of labor, when he suddenly finds himself thrust into the industrial city with its multitude of chimneys and substantial brick buildings, which have been built on such a modern scale by the Pinghsiang Colliery Co. As the mine is in the heart of China, far from the source of machinery supplies and the like, it is necessary to keep complete repair shops as well as shops equipped to manufacture,

as far as feasible, all necessary machines and appliances. This saves the time and expense incidental to ordering from abroad. There is a large roundhouse to accommodate the dozen or more locomotives and a large railway machine and repair shop. In the main machine shop are manufactured steam engines, compressors, pumps, lathes, and in fact almost everything in the heavy machinery line except electrical machinery. A foundry in connection turns out castings up to three tons weight.

An important adjunct is a series of coke ovens along the railway tracks. These ovens are of the Otto-Koepe type, of which there are 300 in operation. Almost all the coke is supplied to the blast-furnaces of the Hanyang Iron & Steel Works at Hanyang. The coal used consists of the fine material saved from the washing plants and runs not over 10% ash and under 0.05% sulphur. In appearance the coke resembles that produced in the by-product ovens of the United States with a somewhat more silvery lustre. Up to the present, by-product ovens have not been installed for the reason that there has been no market for the tar and ammonia produced. Now, however, there is a good demand in Japan and 60 by-product ovens have been ordered from Germany. Anticipating good use for the tar, the company has erected a briquetting plant, having a capacity of 200 tons of briquettes per day. The briquettes from this plant have been tested in the marine service and have proved satisfactory. Analyses of the coal and coke are given in the accompanying table:

ANALYSES OF PINGHSIANG COAL AND COKE

	Foundry Coke	Smelting Coke	Navy Coal	Washed Coal	Run-of-Mine Coal.

An instance of the broad-minded and commendable attitude of the engineers in charge, their devotion to the cause, and desire to help the Chinese in every particular, is seen in the recent establishment of a school of mines for the purpose of training Chinese in the profession of mining engineering. The school is already equipped with the necessary apparatus and has all the requirements found in the ordinary college course with the exception that the theoretical subjects are not pursued so far. A three-years preparatory course is required before students are allowed to enter the mining course which continues from 4 to 5 years, the first year being devoted to actual work, and study in practical mining and allied work. This is the policy now generally pursued in the technical colleges of Germany. The students are to be given every facility for supplementing the class-room work with the study of the practical methods as carried out daily in the mine, and vacation months must be spent in actual work about

Pinghsiang Colliery, General View.

Transportation of Coal From Railroad to Barge.

Coke Ovens at Pinghsiang Colliery.

the mine and the company will supply and allot the positions. There are now over 60 students in the preparatory course.

The mine is opened by a principal adit 3000 metres in length, and by another short adit which connects with a main working-shaft 170 metres in depth, and a ventilating shaft 110 metres deep. The shafts are round in section, brick-lined, 4½ metres and 4 metres respectively in diameter. Recently a large Fraser & Chalmers hoisting engine with reel and flat rope has been installed preparatory to deep sinking. At the present time all the coal mined comes out through the adits. The beds are now being opened continuously downward and the shafts are to be increased in depth as required. In the main haulage ways trains of cars are drawn by electric locomotives of 10, 40, or 50 hp. each. These were the first electric locomotives used in China and were started in the year 1906.

A feature of the surface operations is two coal-washing plants that were found to be necessary in the production of a grade of coal suitable for coking purposes. The coal is sent over shaking screens which give 4 sizes after the lump is run off over a 30 mm. screen. The material is then washed through a series of coarse to fine jigs, the light products of which all go to the coking ovens while the waste is discarded. This waste is given to independent Chinese coke manufacturers who re-wash the material by hand and turn out large quantities of good grade coke in simple rectangular ovens. This coke is sold for fuel. Fire-bricks of all grades and sizes are manufactured here and are of use especially for the coking plant and the furnaces in the steel works at Hanyang. A large amount is sent into the Oriental market and the demand for the brick is steadily increasing.

Regarding the underground workings and discussion of geological features of the mine, the management prefers not to give complete information for publication at this time. The engineers are working on a report that will give in detail the history of development and describe the technical features of interest. The country rock consists mostly of soft sandstone, and in the mine itself is found a hard limestone with many bands of slate and shale, as well as a large amount of soft clay partings in the coal seams. A great amount of development has been accomplished, and while the real life of the mine is largely conjectural, workable coal reserves have been developed to an extent that gives assurance of a supply that will last several hundred years with an output of 1,000,000 tons annually. The present output is about 600,000 tons per year. The coal is bituminous, there being a hard and a soft variety. The hard coal is found in the smaller seams, and those are worked running from 15 to 75 centimetres in thickness. For the extraction of this coal it is necessary to take out a large amount of slate, most of which cannot be used for filling, but must be conveyed to the dump on the surface from the mouth of the mine. There are 8 inclined tracks running to the slate dumps which are already of immense size. Such a mine as this could not be worked profitably in the United States on account of the high percentage of slate since the labor cost and the cost of washing would be prohibitive. In China, however, miners are paid less than 13 cents gold per day, so that the labor cost is relatively low. There are three hard coal seams of large extent having a pitch of about 12 degrees, which are from 3 to 6 metres apart. They are mined by the ordinary long-wall method, in which the entries are run with the dip and along the strike and all the coal is extracted while advancing. This system of long-wall mining is also used in the soft coal seams, of which there are six. These seams vary in thickness from 3 to 12 metres. Drifts are run for the purpose of ventilation every 20 to 25 metres along the haulage-way and connection made about 70 metres distant from the main gangways to provide the air circulation. In the thickest seams blocks are removed to 3 metres in thickness, and, while the roof is supported with props, the open space is filled with waste and the second cut proceeded with.

The greatest difficulty is found in the maintenance of haulage and passage-ways, because of the tremendous pressure. This makes timbering an expensive item, for the timbers must be constantly replaced. No attempt is made to relieve the pressure on the main timbers by providing auxiliary sets as is sometimes done for swelling ground in America. The roof is allowed to fall until it becomes low enough to interfere with the workmen, when it is cut down and new sets put in. This happens as often as once every four months in certain parts of the mine. The main haulage-way is lined with brick with an arched roof where the pressure is greatest. At other places the roof is supported by steel rails and lagging with brick walls. In the endeavor to maintain permanent haulage-ways where the pressure is great, as many as 10 courses of brick have been used in the arches and in many cases these have failed and crumpled under the pressure. This is the only way the engineers have of ascertaining the relative pressure although such trials are very expensive. In the matter of handling the labor, the management has found it an advantage to let out the greater part of the work by contract to Chinese foremen. It is a policy that is found to be particularly successful with the Chinese. They must be driven to doing right and habitually disobey orders unless constantly watched. The mining of the coal is done at a stipulated price per ton, varying with the conditions of mining, and the contractor must guarantee a minimum of 10 to 12% ash, before his output is accepted. Timbering and tunneling is done at an agreed price per metre. The coal and coke are dumped into steel cars and conveyed over standard track to the port of Chu Chow at which point, along the river, are lined up steel and wood lighters, with barges and junks of various description. These are towed to Hankow by the company's tug-boats in lots of about 1200 tons. At present there is a fleet of 13 tugs employed and the facilities and number of craft are constantly being increased. The handling of the coal affords an instance of how necessary it is to adopt methods to suit conditions in a

strange country. There is no need for the use of large capacity automatic-loading devices such as are used in America, for in China labor costs but about one-twentieth of what it does in America. The coal, after being dumped on the ground along the track in great piles, is conveyed by Coolies who use carrying-poles with baskets attached, holding perhaps a bushel each. There are several hundred of these men constantly at work moving from 1800 to 2000 tons of coal and coke per day from the railroad into the barges.

Transportation is handicapped during the winter season because of low water in the upper Siang river. This difficulty will be eliminated as soon as the railroad is built to the city of Yoh Chau, situated at the head of Tung Ting lake on the Yangste river. Here the company has already bought land on the river front for a future permanent shipping point. The Chinese Government recently purchased the 60-mile Pinghsiang railroad, and is grading an extension of that line from Chu Chow to Chang Sha, a distance of 63 miles. The line will soon be completed to the latter point, which will then replace the port of Chu Chow until the railroad is built to Yoh Chau. A feature of the Pinghsiang Colliery Co.'s operations is the growth and progress, these being evident in the output, in the resultant enlargement and improvement of the plant. The engineers and managers endeavor to turn out high-grade products. The success of the company furnishes an example for future undertakings and gives an insight into what may be expected from the eventual development of China's immense mineral and coal deposits.

Tayeh Iron Mines. Property of the Han-Yeh-Ping C. & I. Co.

Electrostatic Separation

By Henry A. Wentworth

Although electrostatic separation has now been known for some years, even recently I have been approached by engineers of the highest technical standing, and questioned concerning its uses, and the difference in principle between it and magnetic separation, and in such manner as to indicate that the principles of electrostatic separation and especially the manner in which they differ in character and application from those of magnetic separation, are not thoroughly understood even by the technically trained man. Electrostatic separation depends principally upon the difference in electrical conductivity of the particles in a mineral mixture. If we break the circuit of an ordinary lighted incandescent lamp, and insert in the break a piece of dry quartz, the lamp remains without current. On the other hand, if we insert in this break a bar of metallic iron, we immediately have light, which is also the case if we insert therein a piece of pyrite. Thus the pyrite conducts the electric current or charge while the quartz does not. Under the high voltages used in electrostatic separation, many minerals not electrically conductive appreciably at the low voltage used with the incandescent lamp, readily allow the flow of current through their bodies or over their surfaces. Moreover, the ratio of electrical conductivity of the best to the poorest conductors is measured in the millions.

Magnetic separation, on the other hand, depends

for its successful operation upon differences in the magnetic permeabilities of the minerals to be separated; in other words, some of the particles must possess to a greater degree than do others that quality which causes iron to be attracted so strongly to a magnet. Thus, magnetite is strongly magnetic, as we say, and, occurring as an ore of iron, in a matrix of non-magnetic rock, is readily and vigorously withdrawn from the crushed mass when a magnet is brought sufficiently near to it. Few minerals, however, are so easily influenced by a magnet as is magnetite, and thus we find it necessary, in order to utilize the low permeabilities of such minerals as marmatite, garnet, etc., to construct much more powerful magnets. Referring again to electrostatic separation, most of the common sulphides are excellent conductors of electricity, blende being a fortunate exception. Most of the gangue rocks are very poor conductors. Thus one sees immediately the field of application of the principle. As is usual with something comparatively new, the field to which it was first adapted, was that in which no other method had satisfactorily solved the problems. In the realm of complex ores containing zinc, there has been worked out a system, which, although not universally applicable to such ores, is found adapted to a surprisingly large number of our American problems of this nature. The common constituents of these complex ores in the sulphide zone are: galena, pyrite, chalcopyrite, blende, and gangue materials. Of these the galena is comparatively heavy, the gangue materials light, and though there be differences in the specific gravity of the other constituents, these differences are so slight that they seldom offer a means for commercial separation. From a furnace standpoint, it is essential, for maximum recovery at minimum cost, that the lead product (that product which contains sufficient lead or is of such composition as to be accepted by the lead smelter man), be as free as possible from zinc; that the copper product also be as free as possible from zinc, and for reasons of economy, from lead also; and that the zinc product approach, as nearly as it can be made economically, pure zinc sulphide—galena, pyrite, and chalcopyrite being objectionable impurities.

So, in the procedure above referred to, by a mill of jigs and tables, or other means for utilizing the gravity principle, the galena is removed, often clean unless the pyrite be high, when some of this mineral is carried with the galena in order to obtain high lead recoveries, with no detriment to this product as a rule; the gangue rock is washed away; and there is left for separation a mixture of chalcopyrite, pyrite, and blende, all of approximately the same specific gravity. This material is then dried but not roasted, and passed over electrostatic separators, whereupon the highly conductive pyrite and chalcopyrite, together with the remaining galena, are thrown from the blende (or the blende drawn out of them, according to the type of machine used), making products of relatively high purity for the respective smelters. Blende sometimes occurs in association with heavy gangues such as barite and fluorspar. Though ordinarily a very poor conductor, its conductivity can be altered easily and cheaply, making it, superficially, at least, an excellent conductor. Blende occuring in a matrix of barite or fluorspar is often chemically of high purity, so that in these cases the separation gives for a zinc product, a material analyzing high in metallic zinc. Another of these special problems is illustrated by the separation of chalcopyrite and other copper sulphide minerals from such heavy gangues as garnet and epidote. Many bodies of garnetized limestone contain, as their economic mineral, gold or silver-bearing chalcopyrite. Usually the concentration of this mineral in such cases is easily accomplished by electrostatic separation, and it is expected that the commercial perfection of electrostatic separation to the point which it has now reached will promote the rapid development of ore-bodies of this nature, of which there are many in North America, and several extensive bodies are now under active development. There are several special fields to which it is readily seen such a principle as electrostatic separation can be successfully applied, but in the consideration of these special fields, it must not be forgotten that this principle is applicable, and efficiently so, to the usual concentration of sulphides from ordinary gangues, and in dry regions, where water is not readily available, it is in a class entirely by itself. More than this, because of the high efficiency of separation electrostatically with those ores to which it is adapted, a very interesting problem is at present being worked out, whereby at some of the big copper mills using gravity concentration, a lower grade concentrate can be made on the tables, thus permitting a much higher recovery of contained copper, and then this concentrate may be cleaned of its silica by electrostatic separation.

I would also say to those interested in the zinc ores of this country, a few words which, though somewhat foreign to this general talk, I believe will be of interest. In discussing the many patents which it has been my duty to study embracing the numerous principles utilized in ore-dressing mechanisms, there has arisen the question oftentimes, as to whether, if a device were for utilization in the dressing of zinc ores, it would be applicable to the great mass of zinc tailing at Broken Hill, Australia. In many minds, therefore, it seems strange that the fairly successful solution of the Broken Hill tailing problem, has not resulted in the immediate like solution of the problems of our American complex ores. So far as I know, there is nowhere another deposit in quantity, which resembles this occurence at Broken Hill. In most of the American complex ores, pyrite and chalcopyrite play a very important part, whereas at Broken Hill, these minerals are present in the tailing only in small quantities. The problem there is the concentration of a blende high in combined iron (and probably manganese), from several heavy gangue materials, such as garnet, rhodonite, and rhodochrosite, there being no necessity for separation of iron and copper from the concentrate when the gangue is removed. In most of our problems, the essential difficulty lies in the separation of these minerals from the blende before the latter can be marketed advantageously.

Bonanza Copper Mine

By Victor H. Wilhelm

The Bonanza mine in Alaska is the objective point of the Copper River & North-Western railroad, 200 miles in length, and costing approximately $22,000,000. The railroad runs through an abso-

Flag Point Bridge on the Copper River & North-Western Railroad.

lutely undeveloped district possessing no agricultural possibilities. It is financed by the Morgan-Guggenheim syndicate, and will be a scenic marvel. The first 40 miles of the railroad follows tidal flats.

Upper Ore-Bins at the Mine.

At mile 50 is the Miles Glacier bridge. Leaving this magnificent piece of engineering, the railroad is built in solid 'rock-work' up the Copper River canyon. From mile 132, the railroad proceeds eastward paralleling the Chitine river at a distance of a few miles to the mouth of the Nizina. The Nizina is followed to the Kenneeott, 4 miles from the mouth of which is the lower camp of the Bonanza mines. The camp consists of the bunk-house, mess-house, warehouse, barn, assay office, and the saw-mill operated by steam. All the machinery and supplies have been freighted from Valdez, 180 miles distant, by means of horse-sleds, at a minimum cost of 14c. per pound. R. F. McClellan, who grub-staked one of the original locators, is the superintendent, and Steven Birch is general manager. The lower camp is connected with the mine by a Bleichert tramway, 15,000 ft. in length, with a difference in elevation of 4000 ft.

The Range From the Railroad. The Arrow Indicates the Situation of the Mine.

The tramway has a minimum capacity of 300 tons in 24 hours, and cost $400,000, most of the cost being due to freight. The tram discharges at the lower end in bins, directly beneath which, on the hillside, a concentrator will be built, foundations for which are being laid. There are in all about 2000 ft. of mine workings, the highest adit being at an alti-

Lower Ore-Bins.

tude of 6200 ft; the lowest about 100 ft. below.

The ores are chalcocite and azurite, the latter appearing on the surface of the chalcocite. From the lower tunnel a raise passes through 40 ft. of solid chalcocite, no limestone being visible. There is also

a 235-ft. drift running through the same ore, all walls showing solid chalcocite, with cross-cuts of 20 ft. showing the same. At present 6 men are working at the mine, though 30 are employed at the lower camp. The track for the ore-cars runs from the main adit to the upper ore-bins over a slide which is said to average 20% copper. This slide contains boulders of chalcocite weighing as much as 200 lb. It has been estimated to contain $8,000,000 worth of copper. The tramway and concentrator have been built to handle the ore from the slide. A switchback and main adit to tap the ore at depth has been planned for the main orebody, which is 40 ft. thick and of undetermined extent in other directions; it dips back and down, so that the two original adits driven in at the outcrop run through it and situated 100 ft. below, found ore at a distance of 100 ft. The ridge of the mountain shows an immense outcrop along its entire length. The same company owns the Jumbo mine, which is said to be an even more extensive property.

INVESTMENT POSSIBILITIES OF NEW DISTRICTS

By A. H. Martin

The average mining investor is prone to purchase stock first and investigate afterward. Lured into haste by the glittering prospectus laid before him, and fearing that he will be unable to secure the offering at present prices, unless he send in his money by return mail, or by telegraph, the investor parts with his cash. A few weeks later doubts assail him, and he proceeds upon a tardy investigation, often with the result that his golden illusions vanish, and he comes to the conclusion that mining is a swindle. Had he exercised the same care in his mining venture that he does in ordinary business pursuits, the investor would have been spared financial loss, and would have been able to select stocks of merit. The ordinary stock-buyer is inclined to place too much reliance on the local newspapers sent out by a certain type of promoters. He believes that the camp publications portray conditions as they exist, entirely overlooking the fact that most of these papers are anxious to bring in capital to exploit new ground, and are usually subsidized by the companies they are booming so zealously. He does not consider the effect of environment, nor how easily the minds of men are excited in a new mining district by surface indications. In most instances the discovery of a small streak of rich ore in the outcrop is hailed as the discovery of a new Mohawk, and the far-away investor, reading the account of this discovery in the booming camp journal, concludes that the times are propitious for the garnering of fortunes. For accurate news from mining districts, the investor will find it to his interest to consult the news columns of a reputable mining journal. By means of various experts' reports, the editor is able to detect any attempt of the correspondent to over-state the fact, while his familiarity with the industry at once shows him whether reports are unduly exaggerated. The average correspondent of a mining journal is an all-round experienced man in the industry, and is careful to avoid statements reflecting on the accuracy of the publication he represents.

Proof that high-grade ore exists in a district is not always a demonstration of the district's merit. The ore may be of such a refractory nature that its treatment involves a long haul to distant smelters, with attendant heavy transportation cost, or it may necessitate erecting a costly reduction plant at the mine. The mining literature of many promoters sparkles with allusions to $1000 ore, but it is not stated that this grade is only occasionally found, and in such small quantities as to make it of little importance. Again the prospectus may describe the development of a vein of $100 ore, without stating that this is found in a small streak of the vein, which may not run above $5 per ton throughout its entire width. The safest way of determining the merit of a new district is to consult the reports of recognized engineers and geologists. These men, through long acquaintance with various districts, are not influenced by every find made in new territory, but are rather inclined to question every report, and to doubt until convinced by irrefutable evidence. Accordingly the reports of such experts may be considered as accurate, with a tendency to moderation instead of exaggeration. Too much attention should not be paid to the statements of irresponsible talkers, for many of these people have claims to sell and highly color every discovery reported. It has been said that the small investor should never invest in any but a proved mine. To invest in prospective producers is speculation, though to the man who is willing to risk his money in speculating, the mining industry offers possibilities of tremendous magnitude. The claim of today, with stock selling at 5c. per share, may be the bonanza of tomorrow, with stockholders declining offers of many times the former price. Many great fortunes have been made by buying stock in a prospect. Still this does not constitute a safe investment, for the chances are overwhelmingly against an unproved claim. Ordinarily the buyer secures a big block of stock, and when the company fails, loudly proclaims that mining is a gamble, with the cards stacked against the unfortunate victim. Yet if that same man were asked to put his money in a business venture in which the chances against success were evident he would denounce the promoter. The great trouble lies in the fact that he failed to investigate adequately before he bought. Aside from the question of ore reserves, the power, water, and transportation conditions of a district are large factors in the successful operation of properties. High gold content of ores may be more than offset by excessively high operating costs. In this way the mine with $50 ore often proves less remunerative than a property containing $5 ore but which is situated in a district where working costs are low. In investigating a new district, all these factors should always be given due attention.

Turn-sheets of steel are used in the best regulated mines in preference to turn-tables, as the latter, if not well built, give much trouble and require many repairs.

The Black Hills of South Dakota—V

By William H. Storms

Not the least interesting of the economic deposits of the Black Hills region, are the placers of the central Hills. These placers are of several periods, geologically speaking. At Rockerville is found an ancient conglomerate, similar to that near Deadwood, and like the latter, lying at the base of the Cambrian. These Cambrian deposits are the most ancient placer deposits in the Black Hills, if not in the world. The other forms of placer deposit in the central Hills are the high and low bars along the various streams, formed many thousand years ago, when the beds of the streams were at the level where these bars are now found. The most recent auriferous deposits are the gravels now forming the beds of the streams, and some of the dry gulches tributary to them.

The most important streams to the placer miner are Castle and Rapid creeks, and some of their tributaries, although gold is also found on Battle, Spring, and French creeks, and some of the smaller streams tributary to them. Other gold-bearing creeks, in which the amount of gold found was smaller than in either of those mentioned, were Beaver creek, in the southern Hills, and Box Elder, Elk, and Boulder creeks in the northeastern portion. The reason for the irregular distribution of gold in these several streams seems to be wholly due to the occurrence or absence of metallic gold in the veins and rocks through which the streams have cut their channels. As a matter of course, a stream that has cut through a region of gold-bearing rocks, will be gold-bearing throughout its length, from the point of entering the auriferous zone to its mouth, whether the lower portion of the stream be within gold-bearing formation or not, and a stream, which in its meanderings, crosses and re-crosses the gold belt, will probably be enriched to a greater extent than that which crosses the best of auriferous formations but once.

Examination of a map of the central Black Hills, on which is indicated the position of the numerous gold quartz mines, will show that these mines mostly occur within a belt of schists, approximately 5 miles wide at the northern end, near Nahant, on upper Rapid creek, but somewhat wider southward—Mystic lying near the eastern border and the Golden West mine, 5 miles southwest of Rochford, being near the western edge of this zone of auriferous schists and slates. In length the golden strip extends at least 20 miles in a southeasterly direction to the Holy Terror mine, at Keystone, and some distance beyond Battle creek.

In the vicinity of Hill City the gold belt seems to be divided, one branch, the easterly one, going toward Keystone, the westerly one swinging around more southerly toward Oreville, Tenderfoot, the Grand Junction, and other mines on French creek, near Custer. The rocks in this somewhat illy defined auriferous belt, are mostly micaceous and hornblendic schists, and slates, some of which carry an abundance of small garnets, commonly called by the miners rubies. Greenstone dikes, large and small, are common in some portions of the belt, particularly in the vicinity of Rochford and Lookout. In the country about Hill City and southward, granite dikes are very common, and in some of the beautiful parks near Custer, form prominent features of the landscape. Many of these granite intrusions are tin-bearing. Throughout the area of the gold-bearing schists, huge reefs of hard, dense quartzite occur, but as far as I am aware they are not gold-bearing, or only slightly so, though to the westward similar quartzites carry copper.

The degree to which the several streams were enriched with placer gold, seems to have depended largely, in most instances, upon local causes, such, for instance, as the occurrence of a vein or belt of schist in the immediate neighborhood, carrying gold, through which the stream must have cut its way. This applies more particularly to the larger streams, like Castle or Rapid creek, for there are many small dry gulches which were rich in coarse gold, but throughout the entire length of which no vein, or zone of schist, or other gold-bearing rock has ever been found.

These dry placers are rather difficult to understand. Most of them are in shallow 'draws' (a name for the flat depressions at the head or along the course of larger gulches), and are dry as are also usually, the larger gulches or ravines to which they are tributary, except at times of heavy rains, or perhaps in the spring when the snow is melting. Many of the richest draws were on the summits of high hills or ridges, with no higher ground in the vicinity from which the 'wash' with its accompanying gold could possibly have come. Often the material in which the gold was found on the hilltops was light, dry, and ashy—the most unpromising stuff in which to search for gold. Not only this, but in many cases the gold was found actually among the grass roots, or but a few inches below the surface, and often 2 or 3 ft. above bedrock, while little or no gold would be found directly upon the bedrock itself. Such instances were of comparatively rare occurrence, however, for as a rule the gold was found upon the bedrock, or in the crevices between the blocks, down into which it was frequently found to have worked its way to the depth of several feet.

Another curious thing about these high, dry placers was that the wash contained many pebbles foreign to the locality. Particularly noticeable were those of an extremely hard hematite, none of which could be found in place within many miles of these diggings. These fragments of hematite ranged in size from grains, like sand, to cobbles, as large as one's head. They were worn perfectly smooth and were almost polished by the attrition of the stream which brought them to their elevated position on the summits of these Castle Creek hills. Many tons of this 'iron-rock,' as the miners called it, may be seen about the old placer dumps of the region under discussion—on the tops of the hills, on the creek bars, and in the beds of the streams.

The only hematite ores at all like those found in

these placers, that are known to me, are to be found in the sedimentary beds lying to the westward of the placer fields, distant 8 or 10 miles. In the Cambrian and Carboniferous formations are to be found occasional small beds and nodular masses of hematite ore, although I never saw any there that were as hard as these pebbles of the placer region of Castle creek. A mile or two above Deerfield, on upper Castle creek, are large bars of gravel lying 15 to 25 ft. above the stream, which here runs through a broad open valley, that is, it is broad and open as compared with the rugged narrow canyon into which the creek plunges a few miles below Deerfield. These gravel beds, above Deerfield, contain the same kind of hard purplish hematite pebbles as those found on the summits of the hills near Castleton, and 600 ft. above the bed of Castle creek. It is important to note, however, that the altitude of the gravel beds near Deerfield is 6000 ft., and that the iron-bearing auriferous gravel on the summits of the hills near Castleton, are found at an elevation approximating 5500 ft., a difference of 500 ft. The distance in a direct line from the gravel bars above Deerfield, to the placers near Castleton, is 7 miles, which gives an average fall of over 70 ft. to the mile, a grade sufficiently heavy to have carried the detritus of the high placers to their present position from the higher country west of Deerfield, at a time when the Algonkian schists and slates had not been eroded as deeply as we find them now, and when a stream may have existed, the only evidence of which remains in these deposits of gravel on the tops of the hills, and which have long since been greatly modified and distributed by erosion, a condition not difficult to understand in a region subject to the terrific downpours and cloud-bursts that are known to occur in the Black Hills, even to the present day.

Notwithstanding the fact that the placer wash of the higher bars and that on the hilltops came from the region miles to the westward, the gravels did not become notably gold-bearing until the ancient streams entered the auriferous belt. Within this zone the gravels all contain some gold, and in places the deposits were rich, thousands of dollars being washed from each of numerous small gulches or draws. Such were Hoodoo, Moonshine, Friday, Grasshopper, and some others. The gold was uniformly coarse, nuggets worth $2 to $20 being common, while fine gold was comparatively scarce. As a result of this condition the miner either had good diggings or he got practically nothing for his labor. However, the personal equation was a large one, as it usually is. I have known good workers to labor steadily for several days without finding enough gold to pay for their salt, and then, in the same diggings, to find several nuggets in a single day, for the ground was what is known to miners as 'spotted.' Generally, however, the pay was more even than the above instance would indicate, that is, where there was any pay at all. Few miners had the patience to work day after day without finding something to reward them for their labor, and it is my belief that there still remains rich places in these diggings which were undiscovered by the early-day miners in their undue haste to select the best diggings always.

Rapid creek runs in a direction a little south of east, across the gold belt, and from the junction with its tributary known as the South Fork, makes comparatively few large bends. It was profitably gold-bearing from the vicinity of the forks throughout the remainder of its course through the Hills, but Castle creek is probably the most crooked stream in the Black Hills. From its sources in the high limestone plateau, near the Wyoming line, it flows in a nearly straight southeasterly course to Deerfield, just below which it takes a bend to the northeastward, and thence, with many a crook and turn, continues in that general direction to the vicinity of the Golden West mine, 2½ miles west of Lookout. About here it enters the gold zone, and the stream turns in an easterly direction entering a deep and rugged canyon. Throughout the auriferous belt the stream is very tortuous, winding its way in and out among the rocks of the gold region. It cuts through the old crystalline rocks from the Golden West mine for 15 miles to the junction of the stream with Rapid creek (the direct distance being about 7 miles), and the fall about 800 ft., or approximately 50 ft. to the mile along the stream. The fall of Rapid creek is much heavier, being about 100 ft. to the mile where it passes through the gold belt, in a distance of 7 miles, from the forks above Rochford to its junction with Castle creek, 2 miles below Mystic. As a result of these varied conditions Castle creek is richer in gold than Rapid creek, the former cutting through the auriferous rocks twice the distance that Rapid creek does, and having a lighter grade, the gold found lodgment in Castle creek more readily than in Rapid.

Southward from Castleton, now only a small cluster of houses, but at one time a good-sized and prosperous town, there have been found from time to time numerous rich quartz deposits, where mines have been opened, among them being the Queen Bee, the Gold Dirt, King Solomon, Bengal Tiger, and numerous others. The ore found in these veins, or lenses of quartz, in these mines in early days, was sometimes astonishingly rich in gold, and it was, without doubt, rich deposits of gold such as these, that enriched the placers, both the high deposits and the stream beds as well.

Some of the placers on the high ridges were peculiar and interesting. At one place, a few hundred yards from upper Hoodoo gulch, two little draws had been worked out by miners. These draws headed on a small flat, on the brow of a steep canyon, called Last Chance. They were not over 150 ft. in length, and the bedrock near the edge was less than a foot from the surface. The pay-streaks had been followed in these draws to within 30 ft. of each other at their head. A small tract of ground, nearly flat, separated them. It had not been worked. I came across this place, and while examining it the thought presented itself—"If these two draws paid well, why not the flat between them?" A sack of dirt was carried down into the canyon 300 ft. below and the result of panning was over $3 in coarse gold. The place was then worked until it was exhausted and paid

about $15 a day while it lasted, which unfortunately was not long. While working this ground the bedrock got deeper as the diggings advaneed. Prospecting here developed the fact that the gold was to be found almost wholly in the grass-roots, 2 ft. above the bedrock. The hill sloped upward gently for a few feet and then the drainage was in the opposite direction. Just how the gold came to be lodged at this place on the surface of the ground, which was a dry and ashy material, the result of the decomposition of soft mica-slate, it would be difficult to say.

Half a mile from this place was a flat, dry gulch known as Grasshopper, so called because the first miners in the gulch were from Nebraska. Tributary to Grasshopper were a number of small gullies and flat draws. Of these, two attracted my attention. Each was about 100 yd. long; they were parallel, crossing the same formation and as far as one could see, were as much alike as two draws could be. They were not over 100 yd. apart. One of these draws produced several thousand dollars in coarse gold, the other, though tested by a dozen prospect holes, failed to show a color. Things of this sort were not an uncommon experience in these diggings. Gold was found in the most surprising places, but was often absent where any intelligent and experienced miner thought he had a right to expect to find it.

At two places on Castle creek gold was found in profitable amount where least expected. These occurrences were each over 300 ft. above the creek, and were found in a sort of depression between the spurs. They were about a mile apart. Generally bars, whether high or low, are on the points, or spurs, but these two places were back in the hollow, as it were, of the hillside. One of them was found by a tenderfoot, who knew no better than to prospect in such a place; the other find was due to the discovery of a nugget on the trail where it was exposed by the rain.

There were numerous bars worked with success along Castle creek in the early days, among them Sullivan's, Billing's, Driver's, and the Elkhorn bars. Driver's bar, although the smallest of these, was to me the most interesting. A prospector named Driver was the original locator, but he found no pay, and no less than a dozen others tried it later, but failed to find the pay-streak. At last one came who tried on the lower side of the bar, all of the other efforts having been confined to the upper side. This last one struck it, and worked the bar out. He was employed there for several years and took out a large amount of gold.

Castle creek is one of the largest and most beautiful streams in the Black Hills, flowing the year round. Bedrock is generally deep in the gold region and a number of attempts were made in early days to work its bed by sinking shafts, the water to be controlled by means of pumps, but these efforts were without success. At Sitting Bull (now Mystic); at Castleton, and four miles above that place near Wheeler Hill mine, pumping plants were installed, and although splendid prospects were obtained at each place, the miners were unable to control the water. At the last-mentioned plant the men succeeded in reaching bedrock at 30 ft. and drifted 10 ft., putting in two sets of timbers, the men standing up to their waists in water before the job could be finished on either set. Notwithstanding all of these drawbacks and difficulties, gold to the value of $110 was obtained from bedrock in this drift, but the water drove them out and the bottom of the hole has never been seen since.

Among the men of those early days were some interesting characters. Many were roisterers, spending nightly in the saloons, the dance-halls, and at the gaming tables, in Castleton, the result of the day's hard toil. Others were careful, living frugally, saving all they could. Some were reserved, taciturn, and non-communicative. Among the latter was one old fellow—Dan Pugh. When the Montana crowd struck Hoodoo gulch, Dan was with them. He took a fancy to a certain location, just below a bend in the gulch, but a younger man got a stake up first. Dan said nothing at the time, but wandered on over the low ridge into the next gulch, which was Grasshopper, where he took up a claim and worked through the season alone, a dangerous thing to do, for Indians were bad.

Nightly, when the Hoodoo fellows would get out their sacks and gold scales and 'weigh up,' they would show from half an ounce to an ounce or more, each. Dan would sit silently by himself and carefully weigh out his little clean-up, meanwhile mumbling to himself, as he placed the golden grains in separate bottles—"That's for grub; that's for tobacco; that's for poker; that's for whisky; that's for me"—the entire amount seldom exceeding $2 or $3 daily, and none of it was coarse gold. With the approach of winter the ground froze and the miners began making preparations to leave the diggings on Hoodoo, from which they had already taken the cream. Weighing up for the season was going on, the various members of the party being able to show from a hundred or two hundred dollars, to over $5000, according to their success in the gulch, and to their frugality in spending.

Dan had declared his intention of remaining throughout the winter, and as usual, sat alone weighing up his little hoard. It seemed pitifully small for a man who was not a 'spender,' and some of the fellows, generous and kind of heart, quietly discussed making up a purse for 'Poor Old Dan.'

One of them said to him: "Dan, you might just as well have come in with us. You could have, you know, at any time, if you would, and had you done so you would now have a good buckskin full instead of that miserable little pile of dust."

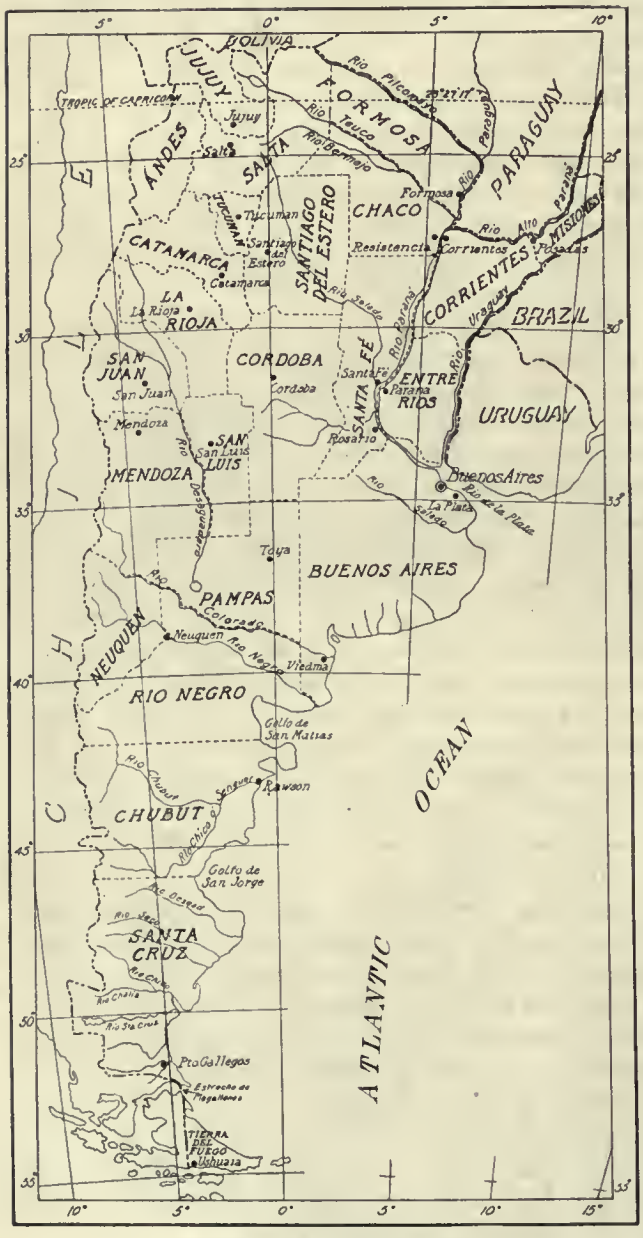
Dan nodded quietly, and with a sly twinkle in his eye, replied: "Thanks, boy. You mean well, I know, and I appreciate it, even if you did take the claim I first wanted, but this here little pile is my fine gold —now let me show you my nuggets," and the eager and astonished miners gathered round and watched 'Poor Old Dan' dig out from various receptacles nearly $15,000 in coarse nuggets.

They were simply speechless for a minute or two, and then they proceeded to open up on him in true miner fashion. Some laughed and commended him for his slyness while others cursed him roundly.

Mining in the Argentine

By Charles Janin

*The mineral resources of Argentina have attracted little attention as yet, and the lack of transportation facilities has greatly hindered development. The prosperity of the country is due to the export of grains, live stock, and timber; the latter from the northern provinces. Some of the provinces are rich in gold, silver, and copper, and a few deposits of salt and borax have been successfully exploited. Petroleum is found in Mendoza,



Map of the Argentine Republic.

Chubut, and Neuquen territories. In general the climate is temperate and healthful, though in the extreme north it is very hot. The people are mostly Spanish by descent though there is a large foreign element, Italians being most abundant. A great deal of British capital has been invested in Argentina mostly in railroads. The standard coin is the gold peso which is worth 96.5c. Under the conversion law of 1899 a paper peso is worth 0.44 of a gold peso.

The gold districts, with the exception of those in Tierra del Fuego, are situated on the eastern slope of the Andes. The best known mines in the Republic are those of the Sierra de Famatina in La Rioja province where the Famatina Mining Co., an English concern, commenced work in 1824. These mines have had a varied career and have been closed down numerous times. In 1903 the property was taken over by the Famatina Development Corporation, Ltd. The region is barren so far as animal and vegetable life is concerned, while water is obtainable only by the melting of snow or ice. The ore is mostly copper but contains some gold and silver. Auriferous alluvial deposits are found in Jujuy province, in Famatina, and the eastern portion of Tierra del Fuego. Gold is also found in San Luis, San Juan, Tucuman, Catamarca, and Salta provinces. The goldfields at the head of the Neuqnen river in the Cordilleras have been successfully worked for years by Chileans with their primitive methods of ground-sluicing. Dredging in the northern rivers has not hitherto been especially successful. In the Jujuy province the Orosmayo Gold Dredging Co. worked up to September, 1908, at which time operations were suspended. Another company, the La Orosmayo Segunda, abandoned its workings without having started its dredge.

In La Rioja province, La Compañia Rioja Aurifera, floated in Buenos Aires with a capital of $750,000, operated a dredge from September 1907 to February 1908, but afterward sold its holdings. A number of concessions have recently been granted for prospecting alluvial gravels, and while definite information is not at the present available, it is reported that several dredges will be installed. Considerable prospecting was done for tin in the Velazco district, but the ore developed, however, only averaged 1.5% and work was abandoned. In the Famatina district, the Famatina Development Corporation, Ltd. installed a 150-ton water-jacket furnace and four converters. The mines of the company are connected with the Ferrocarril Argentina del Norte by an aerial tramway, built by the Government at a reported cost of £200,000. The mining company built a branch line about 800 metres long. The Government tramway is a splendid piece of work. It is about 34 kilometres long and passes over many deep gulches, the longest span being about 840 metres. Work has been concentrated at the San Pedro, Upnlongos, and Atacama mines. In January 1909, 204 men were at work, and during 1908 2754 tons of matte was produced. The mines are among the highest in the world, being 16,500 ft. above sea-level. The mountains at the back rise to an altitude of over 20,000 ft. El Obero Negro, the highest, is in the region of perpetual snow. The country rock is a metamorphic clay slate intersected with dikes. The mines are worked through adits, which in the Upulongos mine, reach a depth of 750 ft. below the surface. Considerable ore, having a value of 5 to 10% copper and from 0.2 to 0.27 oz. of gold, is said to be blocked out. The cost of mining including delivery to the smelter, is given at $5 gold per ton, and smelt-

*Part of this article has been tranlated from *El Padron Minero*, Buenos Aires, 1909.

ing at $6 per ton. Freight from the smelter to the steamer is $12 gold per ton of matte. The ore is rather friable and there is considerable loss of fine material. To overcome this, it has been decided to install a briquetting machine. About 590 nominal horse-power is obtained from water delivered through pipes about two kilometres long to Pelton wheels. La Compañia Minera Los Bayos which owns most of the mines at Los Bayos suspended operations during 1908 until a better method of ore treatment should be found. The ore averages less than 3% copper. The Rio Amarillo Copper Mining Co. has a 30-ton water-jacket furnace and treats a total of about 4000 tons of ore, producing about 600 tons of 45% copper matte. Most of this ore came from the San Juan mine. This company secured a legal suspension of operations for two years commencing October 1908. The Sierra de Minas district is attracting now more attention; gold, silver, copper, and lead ores are found, some veins containing free gold in appreciable quantities, claimed to be from 30 to 90 grams per ton. The ore shipped from one mine it is said averaged 53.8 gm. gold per ton. Wood and water are plentiful.

In La Carolina district, Province of San Luis, wolfram mines are successfully working. The ore is low in grade but hand-picked ore and concentrate shipped to Europe average 65 to 70% WO_4. Considerable ore is claimed to be blocked out ready for extraction. The company washing the gravel on the Canada Honda is said to be meeting with success; the value of the ground worked is given at 5 to 25 gm. gold per cubic metre. The pay-dirt generally lies under a top soil of 5 to 7 metres. The onyx mines in the same district have been successfully working for some years.

In the Territory of Neuquen, the Neuquen Proprietary Gold Mines has a 10-stamp mill which began work in March 1908, and during the year treated 3680 tons of a gross value of 42.074 gm. gold, or $38.320 national currency. The mill treated from 16 to 20 tons per day of 24 hours, power being furnished by a Pelton wheel. The conditions of this district are favorable for gold mining; water is abundant and can be used for power at certain seasons, the Neuquen river alone constituting an enormous reserve. Wood is not always abundant. In the forests of Antueo and Lagunitas about 60 miles distant, wood is cheap; but transportation greatly increases the cost at the mine. The climate is good. In the winter season, June to September, there is some snow, but not enough seriously to interfere with the operation at established mines. The altitude of the known mines varies from 1000 to 1600 metres above the sea. Wages are rather high, being 5 pesos per day for miners and 2.50 to 3 pesos per peon, reckoned in Chilean money.* Contracts are taken for 25 to 35 pesos per metre for drifts 1.8 by 1 metre, and 30 to 35 pesos for shafts in rock of medium hardness. Explosives and candles are furnished by the company.

In the Territory of Las Andes, the mining district San Antonio de los Cobres is situated about 4200 metres above sea-level, and about 150 kilometres from Cerrillos on the Ferrocarril Central Norte. The district has few natural advantages. There is no pasturage for animals, water is not abundant, and there is little wood or other fuel except roots called *yareta*, for which ₱20 a ton, Chilean money, is paid at the mines. Freight on ore from the mines to the railroad is ₱35 per ton. The most important work that has been done in the district is at the Concordia group where a considerable tonnage of ore is blocked out. La Candeleria shaft is 138 metres deep with several drifts at various levels. Electric power is developed at the Chorrillos river, a short distance from the mine, by means of a 250-hp. turbine wheel, and transmitted to the mine at 4500 volts. During the latter part of 1908, about 5300 tons of ore was treated. The first concentrate assayed 6% copper, 30% lead, and 150 oz. silver per ton, but several improvements and changes in the machinery raised the grade to 7% copper, 35% lead, and above 200 oz. silver per ton. Wages paid average about ₱3 per day, Chilean money.

There are a number of old mines in the Province of Catamarca. The ores contain principally copper, silver, and some gold. Lack of transportation has been a serious drawback to development of the mines. It was expected by the end of 1909 that a branch of the Ferrocarril del Norte would be finished from Mazan to the mining district of Andalgala. The Capillitas Copper Co., in this district, has built two 50-ton water-jacket furnaces to treat its ore. The Capillitas mines have been worked without interruption since 1853. Freight on matte from Muschaca, where the smelter is situated, to Chumbicha costs ₱45 Argentine currency. This rate will be greatly reduced on the completion of the railroad. The Capillitas company has secured a legal suspension of work for two years.

Legally mines in Argentina come under three classes:

1. Mines of the first class which belong exclusively to the Government and require concessions to be worked by private parties. In mines of this class the ownership of the surface is entirely independent of the ownership of the mine. Under this head come: (a) gold, silver, copper, platinum, lead, iron, zinc, tin, nickel, cobalt, bismuth, manganese, antimony, arsenic; (b) coal; (c) bitumen and oil; (d) precious stones.

2. Mines of the second class are in two divisions, those which are granted in preference to the owner of the surface, and those set apart for common use and worked by whosoever desires under existing laws. The mines under the first division include deposits of borates, salts, mineral earths, and any metals not mentioned under mines of first class. Under the second division are (a) all kinds of metalliferous sands and precious stones in river beds; (b) placers; (c) tailing and slag piles of abandoned mines.

3. Mines of the third class belong exclusively to the owner of the surface, and comprise quarries for building material, and so forth.

*A Chilean peso is worth about 36.5c. United States currency.

Rapid Electrolytic Method of Analysis

By R. C. Benner

Electrolytic methods of analysis have for some time been of importance in giving a satisfactory and accurate means for determination of a number of elements. A great disadvantage as to practical application, however, has been the consumption of time in the deposition of the metal. The older methods, in many cases, required from 3 or 4 to 15 hours. Notwithstanding this great drawback, they have been successfully utilized in many places, for the determination of copper, lead, nickel, and other metals.

The rapidity with which a quantity of metal is deposited electrolytically, in weighable form, from a given electrolyte of definite volume, depends upon two factors: (1) Amount of electricity passed through the cell. (2) The number of ions present at the surface of the electrode.

The amount of any element deposited by the electric current depends upon its electrochemical equivalent and is proportional to the amount of electricity passed through the cell. In order that it be deposited in an adherent and weighable form the current must not be too high.

In order to be deposited, at any given instant, ions of the element must be touching the pole on which the deposition is to be made, and in order that this be true at all times, as long as there are any ions present in the solution, the electrolyte must be agitated, so that fresh solution is always being brought in contact with the electrode on which the deposition is being made. This fact had been utilized for many years by men making the deposition of different metals on a large scale, for other than analytical purposes, before the fact became impressed upon chemists working on electrochemical methods of analysis. This principle has been applied to this branch of analytical chemistry in different ways by many men, with varying degrees of success, and in the greater number of such trials the deposits have been as good, and have been made much more rapidly than by the older methods. They have, at times, likewise, allowed the use of electrolytes, which do not give satisfactory deposits by the slower methods.

In 1902 to 1903, F. F. Exner,* while working at the University of Pennsylvania, agitated the solution by the rapid rotation of the cathode and was enabled to deposit, in a weighable form, in from 5 to 10 minutes, from 0.25 to 0.50 of a gram of many of the metals. About this time, F. A. Gooch, at Yale, was working along the same line, but instead of rotating the cathode, he, in his work, stirred the solution by the rotation of the other pole or anode. His experiments were, likewise, very successful and show that agitation is, without doubt, the point to be considered in the rapid deposition of metals in a weighable form. A quotation from the work of Henry Sand, which states in a concise manner why the use of these high currents is possible, will not be out of place. He says: "It is most probable that high current densities are possible and depend solely upon the rapidity of renewal of the liquid at the electrodes. It is extremely likely that in metal precipitation the potential at the cathode is independent of current density. The great variations observed, when applying different current densities, are almost wholly the consequence of local concentration changes. The great role, which such changes, under circumstances, can play, I showed, four years ago, in the electrolysis of copper sulphate solution containing sulphuric acid. Just as long as copper ions, in appreciable concentration, were present at the surface of the touched electrode, those alone were precipitated. When, however, they had practically disappeared from this touched surface, all copper, migrating in that direction, was, by diffusion, set free simultaneously with the hydrogen. In all instances, as a consequence of the local exhaustion of copper sulphate, in spite of convection, heating, hydrogen evolution etc., over 60% of the current was consumed in liberating hydrogen. On agitating the solution energetically, copper alone was precipitated. Had the purpose of these trials been to determine copper, that metal would, in the first instance, have separated in a pulverulent form; in the second, in a coherent precipitate."

The different forms of apparatus, which have been devised to apply this principal to electrochemical analysis, have been multiplied almost indefinitely. Two will serve as illustrations. Fig. 1 represents one of the most simple forms, in which the cathode is rotated. The cathode consists of a platinum crucible, placed over a cork on the end of the motor shaft, by means of which it is rotated from 400 to 1200 times per minute. The anode, in this form of apparatus, is a common foil electrode, placed as near as possible to the side of the beaker, in which the deposition is made. Fig. 2 is another form of apparatus, in which the anode is rotated by any means at hand and the deposition made on the platinum dish, which holds the electrolyte and at the same time serves as a cathode. One of the more recent devices has been the application of the solenoid. By the utilization of this, it is possible to make the solution itself revolve, by means of the magnetic stress set up within it. This form of apparatus, while allowing of a more rapid precipitation of some of the elements than is obtainable by the older methods, is not equal, in this point, to the rotating cathode or anode.

Probably the apparatus which will prove itself of the most value, especially to the technical chemist, is the gauze electrode recently used by me for the determination of lead and copper.* This, while it has no more, and in many cases, not even as much, surface as the ordinary foil electrode, allows of the free circulation of the electrolyte, when agitated by the rapid evolution of the gas caused by the use of high currents. In form this has the advantage of simplicity and where applicable, it allows of a depo-

*E. F. Smith, 'Electro-Analysis,' 1907.

**Jour.* Ind. & Eng. Chem., Vol. 2, No. 5 and No. 7.

sition sufficiently rapid for all technical determinations, that is, it is possible to deposit all of the copper or lead found in a 0.5 gram sample of copper or lead ore in less than 20 minutes.

Another electrolytic device, which deserves much more attention than has been, as yet, given it, is the mercury cathode. This is nothing more than a beaker of 50 c.c. capacity (Fig. 3) with a platinum wire fused through the bottom, or, better, at the edge, where the bottom joins the side. The platinum wire makes a contact with the mercury, which is placed in the bottom of the beaker, the electrode weighing, when containing 40 to 50 grams of mercury, not more than 80 grams. The solution to be electrolyzed is placed in the beaker over the mercury, an anode introduced, and the mercury made the cathode by connecting the other pole of the battery to the platinum wire, which was fused through the glass. By means of this simple apparatus, it is possible, with currents varying from 3 to 4 amperes,

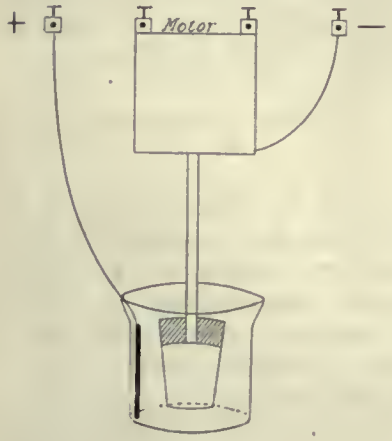


Fig. 1

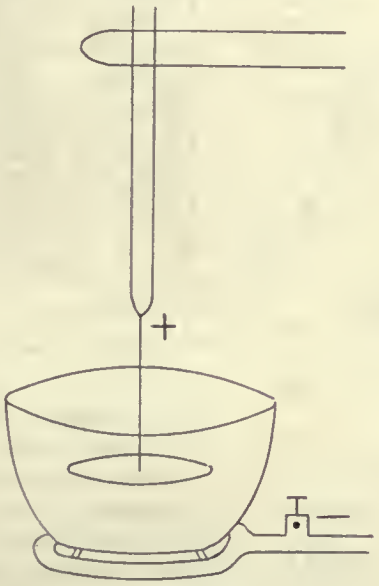

Fig. 2.

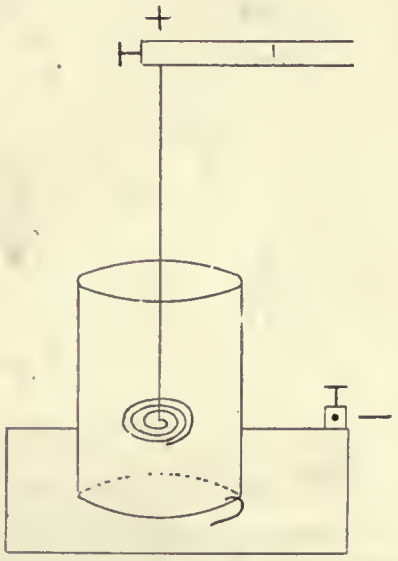

Fig. 3.

where 20 c.c. of the solution is used, to deposit as high as 0.5 of a gram of a number of the metallic elements in from 15 to 20 min. and, by washing with distilled water, alcohol, and ether, to make a determination as accurately as by most other methods, and in some cases, such as that of bismuth, with much more ease and accuracy. Again, some of the most difficult chemical separations can be successfully made by this method. The separation of iron and titanium, in a sample of titaniferous iron ore, will serve as an example. The iron can be quantitatively deposited in the mercury, from a sulphuric acid solution containing iron and titanium, if from 0.1 to 0.2 of a gram of iron be present and the volume of the solution is not too great, in as short a period as 20 minutes. The mercury cathode weighed, before and after, gives the amount of iron present. The electrolyte can then be reduced by zinc and the titanium titrated in the usual manner.

This simple form of apparatus shown in Fig. 3, gives results as quickly as can be desired in most cases. However, they can be obtained even more quickly, if, instead of the stationary anode, a rotating anode be used.

AIR CURRENTS IN MINES

That air currents in mines will have the effect of drying out the natural moisture in the mine air is well known. In this connection a paper read recently by Erskine Ramsay before an engineering society of Alabama engineers is of interest. Mr. Ramsay said in effect that the amount of water an air current will take out of a mine in cold weather is surprising and startling. At Banner the ventilating current amounts to 200,000 cu. ft. per minute, and for the purpose of calculation the inlet and outlet will be considered of equal volume. From the tables it is found that this volume of air when saturated and at a temperature of 40°F. will carry into the mine in 24 hours about 14,000 gal. of water in the shape of moisture. The same current, heated to the temperature of the mine, say 65°F., will carry out of the mine about 34,000 gal., thus robbing the mine of 20,000 gal. each 24 hours. Unless the mine is to be dried out and become dusty, this moisture must be supplied to the air current from steam jets, pools of water, hose, sprays, or other means. At Banner it is sought to supply by sprays at least a part of this loss. The 31 sprays now installed will deliver about 30 gal. per hour, and with all of them working, a total of over 22,000 gal. would be delivered during each 24 hours, or a little more than is taken out by the current.

An open-sight compass, to be really useful, should have the sights perfectly true, and in precise line with the zero lines on the ring. It should be provided with variation-plate in order that the instrument may be adjusted to the magnetic variation at any place that it may be necessary to use it. Its chief requisite is an accurately balanced active needle. An instrument possessing these requisites is sufficiently good for doing work that will prove fairly correct if proper care be taken. A surveyor's compass has the E to the left of the north point, and the W on the right. This is for convenience in reading the bearings of objects sighted from the point of view.

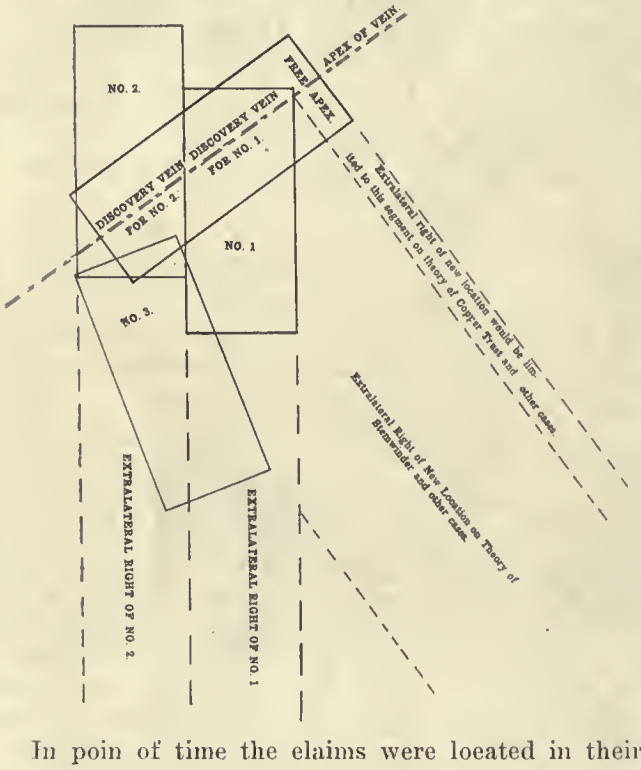
Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Extralateral Right of Cross-Vein

The Editor:

Sir—Would an overlapping claim, as indicated by the sketch below be of any value to the owner of No. 1 for the purpose of controlling a vein supposed to exist as indicated by the broken line?



In poin of time the elaims were loeated in their numerieal order. No. 2 and 3 are owned by another person. Has the owner of No. 1 a right to this supposed vein inside the lines of No. 1 without making this location? Would this loeation give the loeator a right to work the vein aeross elaim No. 2?

L. E. TAGGART.

Forks of Salmon, California, October 7.

[The following opinion in this ease presents the possible diverse views: Insuffieient data are given to discuss the question satisfactorily. The locator has not given the direetion of the dip of the vein and does not state whether the vein indieated is the diseovery or primary vein for both elaims or whether it is only a secondary vein for either or both.

Assuming that it is a primary or diseovery vein for both locations, No. 1 and 2, then by reason of the faet that the vein crosses both side lines of eaeh claim, these side lines become end lines (or, more properly, side-end lines), in contemplation of the law, and their respeetive extralateral rights are determined by vertieal planes passed through these side lines extended in the direetion of the dip. Sinee the elaims No. 1 and 2 are parallel, there would be no conflict of extralateral rights between them.

It is by all means advisable to place a loeation eovering the cross-vein in the manner indieated on the diagram. There should be a segment of free apex of the vein (that is, apex that is not covered by either of the other claims) included in the new location, and the direction of the end lines of the new loeation will be determined by the particular sweep of extralateral segment of the vein that seems most valuable to eover. Of course, the new loeation could not detraet from the extralateral rights of the senior loeations, No. 1 and 2. The right of these loeations would first be satisfied, and then the right of the new claim would eome in to take whatever segment of the vein was left. The question as to whether the new loeation would have an extralateral right from end line to end line beyond the planes of the other extralateral rights, or only for so mueh of the vein in depth as it had of free apex in length, has not been finally deeided by the Supreme Court of the United States. Lower eourts have decided both ways, with the weight of authority perhaps in favor of the exereise of an extralateral right for the full length of the vein, in spite of the faet that part of it lies within a senior valid loeation.

Under no eireumstanees eould the new location be given the right to any part of the vein lying within loeation No. 2 and beneath surface of No. 2. All this proeeeds on the assumption that the vein in question is diseovery vein for both No. 1 and 2.]

Mining Laws of Quebec and Ontario

The Editor:

Sir—I have read Theo. F. Van Wagenen's artiele in your issue of October 8. In it he compares the mining laws here and the elass of prospectors with those aeross the line. There is little eomplaint made here with regard to the regulations governing the aetual working of the mines, or with the staking ont of elaims. At one time, in British Columbia, extralateral rights were allowed, but this was done away with, and the British Columbia mining law is generally aeknowledged to be the best on this eontinent. There is far less mining litigation here than in any eamp as important as this aeross the line, and in any ease the rightful owner gets a fair show, which is more than ean be said of many Western American mining eamps. Several of the bigger mines here are managed by Western American engineers, and they have little fault to find with the laws; in faet, I have heard them state they preferred them to the Amerieaan mining laws, both as far as the prospeetor and miner are eoneerned. Mr. Van Wagenen states that the bulk of the work at Larder, Poreupine, and Gowganda, is that of elaim peggers working in eonjunetion with share promoters. This it not true. I doubt if there is a eamp on this eontinent as promising as Poreupine, where so little 'wild-catting' or 'stoek-booming' has been done. His statement that Sudbury and Cobalt are the only two really proved mineral deposits in eastern Canada, surely is a reekless one and shows his utter ignoranee of the eountry. If the genuine prospector is the kind of man that Mr. Van Wagenen deseribes, we are far better off with the elass of prospeetors in this eountry. They do not seem to have any trouble with the mining law, and for efficieney, they are

quite up to the general run I have found in the West. His contention that the regulations connected with the use of explosives, housing of men, and payment of wages, make prospectors hard to find, sounds absurd. Mr. Van Wagenen is quite wrong when he says it is doubtful if there is a prospector in eastern Canada, and that none will go there until the laws are altered. It would be better if Mr. Van Wagenen came to Canada to learn something about good prospecting and good mining laws, before making such statements as these.

J. Edwards Leckie.

Cobalt, Ontario, October 20.

Northeastern Siberian Co., Ltd.

The Editor:

Sir—During the past year there have appeared several articles in *The Mining Magazine* and the *Mining and Scientific Press* with reference to mining conditions in northeastern Siberia, and to the Northeastern Siberian Co., Ltd., of which I was for years one of the managing directors. Statements have been printed to the effect that the Russian Government violated its agreement with the company and confiscated the company's gold; also that the company itself, in place of carrying on mining operations, was more particularly active in whisky trading with the natives. Both of these statements are wholly untrue. The company's concession covered an area of over 60,000 sq. mi., absolutely unknown as to resources or topography. To carry on prospecting for minerals and other development in such a large, unknown, and inhospitable territory without several bases of supplies would have been futile, so our first task became the construction of four supply stations. Upon our arrival in this territory, we found the natives in the most miserable condition of poverty and disease, largely the results of intercourse with the whaling ships. We decided to try to remedy this state of affairs, and in the course of six years we brought to these natives over 1,000,000 rubles ($500,000) in value in flour, sugar, tea, biscuit, tobacco, lumber, whaling boats, all classes of tools that could possibly be used by them, thousands of Winchester rifles and guns, as well as several classes of dry goods and wearing apparel, also stoves, clocks, lamps, sewing machines, phonographs, etc. Less than one-half of one per cent of our importations were alcoholic beverages. The result of our operations was to change the condition of the natives from one of starvation and disease to comfort and health. The truth of this was, and is, too self-evident to be disputed by anyone, except persons disposed to commit deliberate falsehoods. As for mining, the records and maps show, and fully establish, that we carried on continuous exploration over the whole of this large territory, not excepting the period of the Russian-Japanese war, and at a cost of several hundred thousand dollars, and these explorations resulted in the discovery by us of gold, both in placers and quartz, also of silver, lead, and copper ores, iron ores, and graphite, and our years of operations changed it from an unknown to a known territory. The story of the Russian Government confiscating gold is based upon a clumsy overt act of one of the company's own directors, one Mr. Kovanko, of St. Petersburg, who took in a rather disagreeable manner about $10,000 in placer gold from the foreman of a sub-contractor. The Russian Government had no part in this transaction. On the contrary, the ministers of the Russian Government, by words and by deeds, displayed strong desires to aid in developing the concession territory. My seven years of experience in connection with Siberian development are far from satisfactory, but it was not lack of resources in the concession territory, nor unfriendly acts on the part of the Russian Government that made them so.

John Rosene.

Seattle, Washington, September 28.

Inhalation of Mineral Dust

The Editor:

Sir—Noting the query of 'Drill Runner' in your issue of October 15; is it not possible that the extreme conditions under which the miner works when operating drills afford one of the reasons why he is more liable to phthisis than are millmen? The latter, though in the dust, as a rule, do not exert themselves and are oftener in the fresh air. The trouble is not alone to be attributed to the dust, but in part to impure compressed air and to gases which tend to irritate the lungs. In drilling holes the cuttings are of a sharp form, while dust from crushing machinery in the mills may be of an entirely different shape, much finer, and not so injurious to the men.

B. L. Worthen.

San Francisco, October 22.

VOIDS IN SAND AND BROKEN STONE

A simple and accurate method employed by the Aberthaw Construction Co., of Boston, Massachusetts, for determining the voids in sand and broken stone for concrete work is given in the *Cement Age*, as follows: Apparatus necessary, a galvanized iron ash-can and platform scales that will weigh up to at least 500 lb. Weigh can empty and indicate weight by W. Weigh can filled with water and indicate weight by W_2. Weigh can filled with stone and indicate weight by W_3. Weigh can filled with stone and water and indicate weight by W_4. Subtract W from W_2 and divide by 62.4 to find the number of cubic feet in the can, indicate by C. Subtract W_3 from W_4 to find the number of pounds of water required to fill the voids in the stone or sand; divide by 62.4 to reduce to cubic feet and indicate by V. Then C divided by V will give the percentage of voids in the stone or sand. This method is used extensively by the Aberthaw company, and is accurate, convenient, and quick.

The right of eminent domain as related to mining does not obtain in California or Colorado, although some other States have recognized mining as a 'public use,' and condemnation proceedings for right of way may be instituted under such laws, and such proceedings have been sustained by the Supreme Court of the United States.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

In mica the black and brown geometric figures often seen are due to the presence of tourmaline. It unfits the mica for commerce.

For dampers in ventilating pipes use heavy iron plate. Thin plates are useless, for the concussion of blasts will cause the dampers to double up like paper, destroying their usefulness.

Crushing machinery, engines, and compressors should be placed on concrete foundations where possible, but not before the concrete is set sufficiently to prevent crushing under the weight of the machinery.

Crushing rolls require care in running. One of the most important things is to see that they do not get out of adjustment. If the edges of the rolls do not meet exactly a ridge will be cut on the face of each roll.

Zincblende is occasionally rich in gold. It is frequently high grade in silver and has at times been mistaken for tellurium, as was the case for several years at the Carson Creek mine, in Calaveras county, California.

On a patented placer claim, if, subsequent to the issue of such patent, a quartz vein or other ore deposit be found on the placer, it belongs to the owner of the patented location. Such a vein is not entitled to extralateral rights however.

A 10% grade means a rise or fall of 10 ft. in each 100 ft. In speaking of a grade of 500 ft. to the mile, the mile is measured on the slope and not horizontally. A slope of 10° is not the same as a 10% grade. The former is a rise of 17.2 ft. in each 100 ft. measured on the slope.

Illuminating oil was made in San Francisco, California, as early as 1865-67 by Hayward & Coleman, who were in the oil business. The illuminant was made from crude petroleum obtained near Santa Barbara. This firm also utilized the crude oil as fuel in their distilling operations and in making steam to drive their engines.

Tailing deposited on the land of another becomes the property of the owner of the land, if not immediately removed, and the land owner may work said tailing for his own benefit if it contain mineral of value. On the other hand, if the tailing is damaging to the land owner the person responsible for the deposit of such tailing may be held for any damage done.

The deepest gold mine at present in the world is the Victoria Reef Quartz mine at Bendigo, Australia, the shaft of which is 4355 ft. deep vertically, with a winze from that level that extends 203 ft. deeper—a total depth of 4558 ft. The winze has entered a saturated water-zone at that depth, a most unusual thing in very deep shafts, and it is thought further sinking in this and adjacent mines will be delayed, at least until this unexpected flow of water is under control. Until recently the shaft of the New Chum Railway Co. in Bendigo district was the deepest.

No taxes are imposed in the Argentine on mining properties nor the minerals extracted, and no duty is charged on ore or metals exported. The sole obligation of the miner under the code is that the mine be worked by at least four men for not less than 230 days in the year. Should this rule not be complied with, any person may apply for possession of the property as an abandoned mine.

Where mineral veins cross town lots in the Western mining States, the owners of such veins have the right to the mineral under the surface of said lots. In the event of buildings or other surface improvements being made prior to the commencement of mining operations under such buildings, the miner is responsible for any damage done to said improvements by reason of such mining operations.

When preparing to blast, the miner frequently overcharges the drill-hole, particularly when using a 40% or a lower grade powder. He has learned by experience that a large amount of powder is necessary to break the ground, particularly if the rock be tough. In accordance with this experience he places in the hole about all it will contain, reserving from 12 to 16 in. of a 50-in. hole for tamping. The result is frequently the blowing off of the collar of the hole, leaving the lower end ('boot leg') still in the rock. When this recurs several times it will be found the better plan to use No. 1 powder and high-grade caps, but it will probably not be necessary to fill the 50-in. hole more than one-third full of powder. The holes should break to the bottom and thereby save much time and expense.

The aneroid barometer can be used as a reconnaissance instrument only. For establishing ditch grades and similar lines of gradient it is too capricious. The daily variation while hanging undisturbed on the wall is considerable. For measuring differences of elevation between two points where the observation can be quickly made it is very useful, but if a considerable interval of time elapse the measurement will be unreliable. An excellent barometer indicated an altitude of 1600 ft. It was carried up a hill to the summit of a ridge where it read 1900 ft. Twenty minutes after the first reading, on returning to the gulch the instrument indicated 1615 ft., showing a discrepancy of 15 ft. This is the way of the aneroid barometer. The depth of a shaft can usually be determined with considerable accuracy if there be no delay in going from one level to another, or from the top to the bottom. If there be delay from one level to the next, take separate readings, and then take several trips, reading both top and bottom. From these several readings take the mean, which should agree closely with the actual figures as determined by leveling.

Special Correspondence

TOKIO, JAPAN

Output of Minerals in Japan. — Statistics of Coal Production.

The market during last year, 1909, in view of long periods of universal business depression, as well as the reaction of the financial expansion since the Russo-Japanese war, was inactivity itself, and especially owing to the falling off of value of minerals, the curtailment of enterprise, and the suspension and abandonment of mines, the complaints of miners were unusually prevalent. Nevertheless, the gold, silver, copper, iron, and sulphur showed an increase of 20%, as against 7% for the preceding year. Coal and petroleum remained unchanged. This was due mostly to the fact that the principal mining companies, with comparatively large capital, managed the business well with a view to the requirements of the occasion. The following are approximate figures for 1909, being the output for Japan proper, with the exception of Formosa, Karafuto, Korea, and the concession in Manchuria, and also excluding the output of 160,000 tons of the Government iron foundry under the jurisdiction of the Agricultural and Commercial Department and coal mines under that of the Navy.

	Quantity.	Value, yen.
Gold	142,624 oz.	5,390,705
Silver	4,658,079 "	4,660,716
Copper	75,826,428 lb.	24,325,118
Lead	5,360,658 "	447,615
Tin	38,240 "	30,817
Bismuth	260 "	1,508
Refined antimony	232,113 "	36,860
Antimony sulphide (crude)	102,900 "	9,220
Quicksilver	558 "	705
Zinc ore	16,790 tons	448,212
Cast iron	47,559 "	2,024,318
Steel	6,817 "	534,161
Pyrite	60,146,791 lb.	137,135
Chrome iron ore	1,170,833 "	6,913
Manganese ore	14,681,675 "	56,381
Arsenic	12,064 "	323
Phosphate ore	8,676,950 "	7,362
Graphite	473,686 "	27,657
Coal	14,986,403 tons	61,743,980
Brown coal (lignite)	94,390 "	165,183
Petroleum	66,181,040 gal.	6,369,925
Asphalt	9,301,358 "	89,093
Sulphur	59,530,160 "	55,695,100
Total		107,288,500

As the above figures stand, the mining output amounts to 107,288,000 yen, an increase of a little over 1,000,000 yen or approximately 1% over the preceding year. But as stated above, in spite of the increase of from 7 to 20% in the principal minerals, the small total increase as 1% resulted from decrease in price of other minerals, above all, coal, copper, silver, and petroleum. Following is the output for the previous ten years.

	Yen.
1900	49,267,475
1901	56,705,085
1902	56,129,547
1903	57,475,811
1904	58,461,339
1905	78,101,797
1906	107,967,010
1907	112,015,607
1908	106,274,408
1909	107,288,500

Thus, as in the above table, the mineral output in this country is on the increase every year, and as compared with that of 1900, shows an increase of 90% in gold, 100 in silver, about 60 in copper, 40 in lead, 160 in iron, 150 in coal, 230 in petroleum, about 150 in sulphur, and 190 in other metals, an average increase of 115 per cent.

Coal is the principal of the mineral products, the output forming 57% of the total, reaching in 1909, 14,986,403 tons, valued at 61,743,980 yen, an increase of 161,040 tons or 1.1% over the year before. In spite of this increase in volume, it showed a decrease of 1,879,793 yen or 3% in value, and it is further noticed that the rate of increase in production in 1909 is remarkably small, compared with preceding years. This is due to limitation of output as a consequence of the dullness of the market. Owing to universal business depression, marine transport also suffered great loss, decreasing the number of the vessels, and consequently the demand for coal. Up to the present the market has not been rehabilitated. The authorities drew the attention of the public to the outcome of organization of a coal syndicate in Germany, and desired to apply this scheme to this country, in order to restrict supply to meet demand.

The export for 1909 was 2,844,274 tons, valued at 17,297,139 yen, an increase of 18,842 tons and a decrease of 936,841 yen in value, as against the preceding year. The export to Korea, the Straits Settlements, and America was much decreased in 1909, the principal destination being the Orient; China (Kwantung provinces excluded) leads the rest, taking 45% of the total export, of which Hongkong took 32%, Straits Settlements 8.4, and America 2.3.

	Quantity, tons.	Value, yen.
China	1,269,783	718,842
Kwantung provinces (Manchuria)	20,733	126,820
Korea	99,637	535,509
Hongkong	912,438	5,631,479
British India	56,657	391,772
Straits Settlements	238,811	1,794,278
Dutch India	40,014	322,610
French India	22,287	167,717
Russian Siberia	25,524	171,566
The Philippines	70,053	480,573
England	35,328	176,648
America	28,774	151,833
Mexico	9	84
Hawaii	24,068	162,153

The Fushun mine, acquired by the Russo-Japanese treaty, is full of promise, and is actively in operation, and there is every sign that its product will come into competition with the export from Japan proper.

MANILA, P. I.

Paracale District. — New Dredge to be Bought. — Tumbaga Ships to San Francisco.—Mambulao Iron Deposits.— Surveys by Division of Mines.—Mineral Production in 1909.

News from the Paracale district on the east coast of Luzon is encouraging though there is not as much excitement as there was some months ago due to an incipient boom, the district is really in better shape than it ever has been. The San Mauricio mill, with 20 stamps, is running steadily, having a large supply of ore in reserve. It is still too early to say what results are being obtained. A fine lot of samples came up from Tumbaga mine on the last boat. A large sample will be sent to the Selby smelter in California. A large part of the sample was crushed and assayed in the Division of Mines, the assays running nearly $2000 per ton. This all comes from two 4-in. streaks of calcite in brecciated shale from two raises on the first level. Some of the specimens are exceedingly rich, showing free gold and galena all through the calcite. The minerals in these veins are calcite, quartz, galena, zincblende, gold, and tellurides. At this mine there is a shaft 97 ft. deep to the first level, and 86 ft. below the first level. There are 225 ft. of drift on No. 1 vein of the first level besides 60 ft. of cross-cut and 70 ft. of drift on No. 2 with a winze 36 ft. deep. Vigorous development work continues on the Nalasvetan, Navotas, and Leduc properties. There are only two dredges working in the river near Paracale. The Philippines dredge, which was found unsuited to the ground on

the Paracale river, has been moved to the Malaguit and a bar of gold has already reached Manila from there. The Paracale dredge, the pioneer of the district, has a new pontoon and is working just below its old position on the river. The Stanley dredge has closed down for the present. Testing on Gumaus river has exceeded expectations and on the strength of the results, William Kane, of the Philippine Exploration Co., which has control of some property on this river, has gone to the United States to procure a Bucyrus dredge and the necessary force to run it. It is hoped that a large dredge of the Bucyrus type may soon be placed in the district as it is believed that a great saving can be made by a large dredge. Considerable attention has been given an iron deposit on Calumbayuma islands at the mouth of Mambulao bay. This deposit has been found to continue on the mainland to the south. The Division of Mines has completed a reconnaissance of southeastern Luzon, the field work having been in charge of G. I. Adams. Within a few months a larger party will probably go to the Paracale district for detailed work. The triangulation of the mining district was completed several months ago. The district now has telegraph and telephone connections with the outside world and an extension of the new railroad to Nueva Caceres has been proposed. News from the Benguet district is not so complete. A 6-stamp mill has been set up by the Major Mining Co., and is about ready to run. The plant will be in charge of E. B. Frost, of California. The Headwaters company is erecting its mill, but it will be two

Natives Breaking Rock.

months before it will be running. Arrangements have been completed to restore the plant at the Bua mine in the Antimok valley, which plant was partly destroyed in the typhoon of October 1909. Just what will be done on the Benguet Consolidated property has not been decided. There is talk of consolidating the Benguet Con. with the Camote property. There are many reasons for thinking that this would greatly benefit both properties. Options have been taken on several of the properties but things are still in the formative state. In Masbate, the mill of the Colorado Mining Co. is expected to be running about the first of March. Development is proceeding on several of the properties in this district but there is no indication of immediate operation. Recently samples from placers were brought in from the east coast of Luzon due east of Manila, but no further particulars are available. F. T. Eddingfield, mining engineer in the Division of Mines, is engaged in making a preliminary survey of the Agno Placer Co.'s ground in the Pangasinan province. The Agno flows through the heart of the mineral district of north and central Luzon. The Government coal mine on the west end of Batan island has shut down. A party from the Division of Mines is engaged in making a report for the division commander in the Philippines. Work in the East Batan mine is proceeding satisfactorily. Samples of coal are being collected by the Division of Mines to ship to the Bureau of Mines in Washington for briquetting tests. A gas-producer is being installed in the Bureau of Science in Manila to handle the Batan coal which seems to be particularly suitable for this purpose. The coal deposits in the Philippine Islands are extensive and constitute the most important mineral asset of the country. Several mining engineers from Germany and America are making examinations of various mining fields in the Philippines, and in spite of many setbacks the outlook is more encouraging than ever before. The Division of Mines has issued a pamphlet covering the mining fields during the calendar year 1909. Copies of this bulletin can be secured by applying to the chief clerk, Bureau of Science, Manila. The mineral production for 1909 as estimated from reliable sources, amounted to ₱2,240,047 or $1,120,023. The gold production, while not large, was still in excess of 1908, it amounting to $274,507, the Benguet district leading. Coal amounted to $98,592, and iron to $15,539, most of this coming from three small furnaces owned and operated by a Tagalog woman near Angat in the Bulacan province, Luzon. The output of these crude furnaces is made into plowshares and sold to the natives of the neighboring province.

PARK CITY, UTAH

American Flag Mine.—Its Extent and Workings.

The American Flag mine, situated in Empire canyon, Park City district, Utah, has three veins in quartzite. The main vein strikes north 36° east, dips east 79°, and varies in width from 1 to 6 ft. The gangue material is fragmental quartzite, accompanied by talcose matter in many places. There is also a good deal of iron and manganese. The ore carries gold and silver and varying amounts of lead and copper. The gold is not free, and the silver occurs as chloride, sulphide, and bromide, with small quantities of native silver. The oxidized ore extends to the depth of 1100 ft., below which level the sulphides occur. The hanging wall is quartzite, except on the north drift of the eleventh level where it is limestone; the foot-wall is also quartzite, except where it is displaced by porphyry on several of the south drifts and limestone on the ninth and eleventh levels. The east vein, which has been exposed only on the latter level, lies 75 ft. east of the main vein, and has a strike north 60° east. Therefore it diverges from the main vein on its course north, and intersects the main vein on its course south. The dip of the east vein is 85° west, and it is thought that it will be found to dip into the main vein at a depth of 200 ft. vertically below the eleventh level on the latter vein. The east vein varies in width from a few inches to 1 ft., and it is regarded as a spur from the main vein. Both walls are quartzite, the vein filling is similar to that of the main vein, and the metals, in the order of their relative value, are gold, silver, and lead. The Rodin vein, the first opened on the property, has been mined to a depth of 225 ft. below the level of the Curtis tunnel, which was driven from the bed of Empire canyon. A considerable tonnage of first-grade ore has been mined and shipped from this vein. Its strike is north 35° east, the dip 79° southeast. The bedding planes of the quartzite dip 20° northeast. The Silver King limestone lies above and the Ontario limestone lies below the American Flag quartzite, but the latter limestone has not been found in these workings. There are 9825 lineal feet of development on the American Flag property, consisting of an 1130-ft. vertical shaft, 1590 ft. of cross-cuts, 3100 ft. of raises and winzes, and a 225-ft. incline shaft. The mine production, from August 3, 1904, to September 30, 1908, consisted of 6130 tons of a gross value of $232,879, or an average of $38.12 per ton. The shipment of 2420 tons during another period brings the total production up to $272,235, being an average for all of $31.84 per ton. The gold content averaged $7.58, and the silver $24.26 per ton. F. V. Bodfish and R. L. Mack, of the American Exploration Co. of Colorado, which has a long-term lease on the mine, have prepared an assay sheet showing the quantities of lead, silver, and gold and their total value as the result for 77 samples taken from all parts of the mine. This shows that silver takes first place, gold second, and lead third. The sample lowest in silver assayed 0.3 oz., the highest 303 oz.; the sample lowest in

gold ran 20c., the highest $23.60. They have also prepared a longitudinal section and assay map, outlining development, indicating value of samples at places from which they were taken. Mr. Bodfish makes definite recommendations as to future development, and the costs of same, which will require the expenditure of $5300. The property is well equipped with hoisting machinery, air-compressor, and power plant.

LONDON

Flotation Process at Broken Hill. — North Broken Hill. — Chillagoe Company.—Mining in Egypt.

The latest news from Broken Hill is that the Zinc Corporation is to adopt the process of the Minerals Separation Co. in the extension of plant recently decided on. The Zinc Corporation was formed by Bewick, Moreing & Co. five years ago for the purpose of treating by flotation the large dumps of zinciferous tailing resulting from the dressing of the silver-lead ores of Broken Hill. The hot acid-sulphate process of Potter was at first adopted, but after extended experiments was rejected and that of the Minerals Separation Co. adopted instead. This was given a short trial and abandoned. By this time the finances and prospects of the corporation had become decidedly gloomy. Further money was raised and the Elmore vacuum plant built. Great success has attended the venture since and handsome profits have been made. Some months ago the economic position began to alter, for the average content of the material treated began to fall. At the beginning of operations it was only natural that the best parts of the dumps should be selected, with the inevitable result. In order to maintain the profits with lower grade material it became necessary to increase the scale of operations. During the last three years the plant of the Minerals Separation process has been vastly improved and its efficiency increased. At the same time the design of the plant has been so simplified that its first cost and the cost of operations have been reduced; so much so that the directors of the Zinc Corporation have decided to adopt it. This should give an opportunity for comparing the efficiency and cost of the two processes working side by side under the same management. Not only have the flotation processes been improved but of recent years the lead-dressing practice at Broken Hill has advanced. At the North and South mines the new plants are giving excellent results, and some particulars of their performance will be of interest. The Broken Hill South Silver Mining Co. suffered during the first half of 1910 from the coal strike and during the greater part of January and February operations were at a standstill. Nevertheless the results for the half-year have been good. The new concentrator was erected by the beginning of 1909, but did not start work immediately owing to the difficulty of securing suitable terms for the sale of lead concentrate. Later in the year contracts were made and the mill was fully employed by the middle of the year. During the four active months, March to June, 132,757 tons was mined and delivered to the mill, assaying 15.2% lead, 12.8% zinc, and 6.4 oz. silver. The weekly rate was 6987 tons as compared with 6424 tons the previous half-year, and the metal content showed an increase of ½% in lead and zinc and ½ oz. in silver. The concentrator produced 20,735 tons of lead concentrate averaging 72% lead, 21½ oz. silver, and 5.3% zinc. The zinc tailing produced was 58,915 tons assaying 18½% zinc, 4.2% lead, and 3.7 oz. silver. Some of this tailing went to the Zinc Corporation, but since March the whole output has gone to the De Bavay company. The Zinc Corporation still treats the old dump material of which there is over 1,000,000 tons on hand. The De Bavay company also owns 143,000 tons of old dumps. In addition 215,809 tons of slime has accumulated, averaging 12% lead, 15% zinc, and 6 oz. silver, to be treated when a suitable process is available. The system of filling old stopes with quartz tailing has been extended, and additional rock filling is being provided from a quarry. Developments at the mine are encouraging and on the new level at 1070 ft. the orebody is as valuable as in any part hitherto opened. The cost of mining during the last half-year was 10s. 2d. per ton, development 1s., filling stopes 1s. 1d., concentrating 3s. 6d., total 15s. 10d. The total cost, including extra expenses due to the coal strike, was £125,670, and the income from sales of lead concentrate and zinc tailing was £171,274, leaving a profit of £45,603. Out of this £2900 went in payment of administration expenses and taxes and £5166 was written off for depreciation. A dividend of £20,000 was distributed.

The North Broken Hill Co. is in a satisfactory condition. Not only are developments in the mine excellent, but the new concentrating plant is a great success. During the half-year, ended June 30, the third and final unit of the concentrating plant was put in operation and the amount of ore treated per week has been increased from 4000 to 5200 tons. The total ore sent to the mill during the half-year was 108,943 tons assaying 15.4% lead, 6.4 oz. silver, and 12.9% zinc. The production by jigs and tables was 17,912 tons of lead concentrate averaging 70½% lead, 20½ oz. silver, and 6.6% zinc. In addition 53,688 tons of zinc tailing was produced averaging 17% zinc, 3.6 oz. silver, and 3.9% lead; this was delivered to the Amalgamated Zinc (De Bavay's) company for treatment. A small plant has been erected for the experimental treatment of the slime, of which 11,568 tons was produced during the half-year, assaying 12½% lead, 15½% zinc, and 7.8 oz. silver. The working cost at the mine during the half-year has been 9s. 4d. per ton; at the mill 3s. 1d., and development 1s. 5d., a total of 13s. 10d. The total cost was £77,714 and the receipts from the sale of concentrate and tailing was £124,688, leaving a balance of £46,974, as compared with £33,899 the previous half-year. Out of this profit, £2426 was paid for office expenses and taxes, and £17,783 was allowed for depreciation. The dividends absorbed £28,000 being at the rate of 16% for the half-year. The details given by the manager, George Weir, relating to recent developments in the mine are of unusual interest. Owing to an alteration in its pitch, the southern orebody has been found on the 1100-ft. level at a distance farther away from the boundary than was expected and consequently more ore will be found in this level than on the 950-ft. level. Moreover the content of the ore is higher than the average. This company did not suffer from the recent coal strike.

The Chillagoe company which is registered in Victoria was formed in 1898 to work copper-lead deposits in North Queensland, and has been twice reconstructed. The capital now stands at £500,000 in shares of 10s. each, and in addition there are £773,000 debentures. The company also owns a railway from Mareeba to Chillagoe and has nearly completed a further line, 145 miles long, to Einasleigh and Etheridge. The company has a smelting plant at which its ores and those of the subsidiary Mungana company and custom ores are treated. E. A. Weinberg is consulting engineer, E. J. J. Rodda is mine manager, and J. Horsburgh is metallurgist. The amount of ore raised from the company's own mines is much less than formerly; in fact, the mines are for all practical purposes non-producing. The ore purchased from the Mungana company has been of less value than formerly. If it had not been for ore purchased from the New Einasleigh mine at Etheridge, which is now becoming an important producer, the metallurgical work would have shown a great contraction, and even as it is the furnaces have been running only part time. Recent development has been confined to the Zillmanton mine where work was resumed in August of last year. There is about 40,000 tons of copper ore available for extraction at this mine. During the year ended March 31 the lead furnaces treated 20,051 tons of ore mostly from the Mungana mine and produced 2042 tons lead, containing 137,318 oz. silver, and 5658 tons of matte containing 1061 tons copper and 140,111 oz. silver. The copper furnaces were occupied during the earlier part of the year in the treatment of this matte, but later on, the Mungana lead-copper ore contained so much less lead and so much more silica that it was treated direct in the copper furnaces, so sacrificing the lead content. The amount treated in this way was 8290 tons. The copper furnaces also treated 16,964 tons of copper ore from New Einasleigh. The total output was 2735 tons copper, 283,860 oz.

silver, and 1798 oz. gold. The profit for the year was £88,348 which was earned entirely by the railway; out of this £26,540 was paid as debenture interest and £56,016 written off for mine development and for depreciation of plant. A great deal of work has been done in the investigation of other properties. Of these the most promising seems to be the Big Reef near Charleston in the Etheridge district which in earlier days was worked for gold in the oxidized zone and now is being developed in the sulphide zone.

Mining in Egypt has during recent years been disappointing and though many old gold deposits have been re-opened the results have been indifferent. At the present time the developments at the Barramia have once more attracted attention to the country. The company was formed by John Taylor & Sons in July, 1909, to acquire from the Egypt & Sudan Mining Syndicate, the Barramia gold mine which is situated between the Nile and the Red Sea, 63 miles from Edfu on the Nile. The capital of the company is £55,000 divided into 216,000 10% non-cumulative preference shares of 2s. 6d. each and 112,000 ordinary shares of 5s. each. The purchase consideration was £28,000 in ordinary shares, £1350 in preference shares, and £5000 in cash. The remaining 205,200 preference shares were subscribed in cash by shareholders in the vendor and allied syndicates. The preference shares, in addition to the 10% dividend, are entitled to $^{27}/_{65}$ of the subsequent profits in any one year. The mine has a 5-stamp battery erected by the vendor syndicate. The property was worked by the ancients and it has the characteristic of containing ore-shoots of high value. The vendor syndicate has extracted 1460 tons of ore which yielded gold worth £17,190. The work of the present company has been to hasten developments. During the year ended June 30, 583 tons of ore was extracted yielding gold worth £15,727, and a profit of £3276 was made, so that it has been possible to distribute 10% on the preference shares, absorbing £2700. An additional 5 stamps and other plant are being built, and plans made for a cyanide plant to treat the tailing which assays as much as 8 dwt. Motor traction is being established for communicating with Edfu to supplement the present camel traffic. The report by S. W. George, the superintendent, shows that the mine is in a promising condition and that in several places the ore is highly profitable. He foreshadows the provision of additional plant which will be required for the economical exploitation of the veins below the 250-ft. level. Mr. George is resigning owing to desert life not suiting his health and Arthur J. Rickard is succeeding him.

TONOPAH, NEVADA.

Results of Milling Operations.—Important Developments.— Tonopah-Belmont.—MacNamara.

The Tonopah Mining Co. is mining and milling an average of 15,000 tons of ore per month, this having been the record of the last seven months. The average value of this ore was $22 per ton, of which $6 was gold and $16 was silver. A. R. Parsons, superintendent of the company's 100-stamp mill and cyanide plant at Millers, gives the milling costs at $2.76, and the extraction at 92%; the cyanide consumption was 3.28 lb. per ton; zinc, 1.77 lb.; lime, 9.32 lb.; lead acetate, ½ lb. per ton of ore. There has been little change in milling methods within the last two years, except that the proportion of slime has been increased. As now practised, 46% of the ore is cyanided as slime, and 54% as sand. About the only new equipment added was a Trent agitating tank, 36 ft. diam. by 20 ft. deep. W. H. Blackburn, mine superintendent, states that the Sand Grass 2-compartment shaft has reached a depth of 550-ft., and has been equipped with an electric hoist. This shaft was sunk for the purpose of developing territory at the west end of the company's group. No lateral work has been done as yet.

The West End Mining Co., for which S. H. Brady is manager, has done 3500 ft. of development since April last, and has shipped to the Kennett, California, smelter, 6768 tons of ore of an average value of $20 per ton—$5 in gold, and $15 in silver. The ore for these shipments was taken from stopes above the 400, 300, and 200-ft. levels. The principal orebody is known as the West vein, having an andesite hanging wall, and a rhyolite-dacite foot-wall. The vein width runs 4 to 20 ft., the pay-streak being next to the foot-wall; the gangue consists of quartz, with some rhyolite. Sinking from the 400-ft. station is in progress, the intention being to open a level at 500 ft. The steam-hoist is being replaced by one to be operated by electricity; the air-compressor is now driven by an electric motor. The headframe is to be extended higher, and a self-dumping skip installed. The ore, after it reaches the surface, is dumped into bins, chutes from which discharge it upon a steel conveyor by which it is fed into a 10 by 20-in. Blake crusher. The crushed ore drops into the boot of an elevator, whence it is raised to the top of the building, discharging into a trommel, the undersize from which passes through a hopper upon a belt conveyor which carries it to the shipping bins; the oversize discharges into a Crane spiral washer, set at 30°, the lower end being about half submerged in water. The ore, after being washed by this process, is discharged at the upper end of the spiral cylinder upon a sorting belt that moves at the rate of 20 ft. per min. The sorted ore is carried by the belt-conveyor to the shipping bins. F. M. Smith, widely known as 'Borax Smith,' is president of the West End company, which employs 50 men. The erection of a milling plant is being considered. The Tonopah-

Tonopah-Montana Mill.

Belmont Development Co., whose holdings comprise an area of 116 acres on Mt. Oddie and Rushton hill, is shipping to the Kennett smelter 1500 tons per month of ore that runs $75 per ton, and is treating 6000 tons per month in its mill at Millers; the mill ore is said to run $32 per ton. The ore carries, approximately, 1 oz. gold to every 100 oz. silver. The net earnings for the quarter ended August 31, 1910, were $503,477, and for six months ended that date were $677,676. Those responsible for Belmont operations and results are: Frederick L. Bradshaw, manager; J. F. Fitzgerald, general mine foreman; R. J. King, mining engineer; A. F. Jones, mill superintendent. Great interest now centres in the Belmont by reason of the discovery and development of the new vein which was first opened in December, 1909, by driving, from what is designated as winze 1056, on the 1100-ft. level. This development and discovery was east of the Belmont fault. The new vein, which has an east-west strike and a north dip, has been opened on its dip to a depth of 450 ft. There has been 700 ft. of driving in ore on the 1100-ft. level, and a considerable amount on the 900, 1000, and 1166-ft. levels. Winze 1056 serves as the avenue from which all development has proceeded on the new vein below the 1000-ft. level. It starts on the latter level and terminates at 1166, and inclines about 45°. An electric hoist at the top of the winze hauls ore in mine cars from levels 1100 and 1166 to the 1000-ft. level where they are trammed to the 1000-ft. station of the Desert Queen shaft, through which they are hoisted to the surface. The width of the new vein is 10 to 40 ft., the width of the ore ranging from 10 to 20 ft. In one place a lenticular body of andesite seems to have split the vein. This 'horse' is

of the same material as the vein walls, consisting of the earlier andesite in which the lodes of the district occur. While the Belmont property possesses several other veins which were thoroughly explored at the time of earlier operations, the principal part of the mine force is now concentrated on the new vein, and the production mentioned above seems partly incidental to this vigorous development. The plan is to continue sinking at a place where a beginning has been made below level 1166. The original shaft on the group is known as the Desert Queen, which is 1100 ft. deep, levels from which penetrate all parts of the property. However, by December 1, the centre of operations will be at the new Belmont shaft, situated on the east side of Mt. Oddie, 1900 ft. northeast from the Desert Queen shaft. The new shaft has been sunk to a depth of 1175 ft., and has three compartments, each 4½ by 5 ft.—two for hoisting and one for ladderway and pipes. It is well timbered and ready for use. The two shafts are connected on the 1000 and 1100-ft. levels. An A-type steel headframe has been erected over the new shaft, and the new shaft-house, compressor building, blacksmith shop, change and store rooms, and transformer house, all of steel and concrete, are under construction and nearly finished. A 300-hp. double-drum electric hoist, Wellman-Seaver-Morgan make, with Westinghouse motor, is being installed. A Nordberg electrically-driven air-compressor, capacity of 1800 cu. ft. of free air per minute, has already been installed. The ore-bins are ready, also the tracks leading to them from the collar of the shaft. The railroad track passes below the bin-chutes. A modern office building, two stories high, is finished and ready for occupancy. It includes drafting-room and vaults for valuable papers. The Belmont has 250 men on the payroll at the mine, and 45 at the mill. The MacNamara Mining Co., whose Tonopah holdings lie between the West End and Tonopah Extension groups, has shipped 8000 tons of ore to Coram, California, since March 1, and the average monthly shipment now is 1500 tons. The ore runs 85 to 90% silica, and samples about $25 per ton, one-third of the value being gold and two-thirds silver. Occasional shipments of selected ore had a gross value of $100 to $300 per ton. The 800-ft. shaft serves to open two veins on the property—the upper and the lower. The upper vein, on which the principal development has been done, has an east-west strike and an average dip north of only 20°. It lies between a hanging wall of earlier andesite and a foot-wall of rhyolite-dacite, and ranges in thickness from 4 to 8 ft. The gangue material is mainly quartz, and a highly silicified phase of wall rocks, being an incomplete silicification of them. The silver occurs mostly as argentite, the gold being associated with it. In many places the vein is absolutely flat, and in the flattened sections is found the richest ore. This vein has been opened by levels from the 200, 300, and 375-ft. stations. The lower vein has been partly developed by a level from the 800-ft. station. It has nearly the same strike and dip as the upper vein, but it has a rhyolite-dacite hanging wall and an andesite foot-wall containing much calcite. Its thickness is from 40 to 50 ft., the value of the ore being in gold and silver in nearly equal portions. It is probable that this vein will be opened by driving a cross-cut from the 600-ft. station. The cost of mining here is doubtless increased considerably by reason of the veins being so nearly flat, as little of the ore can be moved by gravity. In sorting the better grade of ore for shipment a large tonnage of mill ore has accumulated on the dump, and much of similar grade is left in the mine. Herbert Haas, who became manager of the property on June 1, states that a milling plant may be erected, though no definite plans for same have been made. With a mill to handle the low-grade ore it would be possible to mine and profitably handle all material between the walls. The property is controlled by California people, J. L. Joseph of San Francisco being president. The development proceeds at the rate of 400 ft. per month. The hoist is operated by compressed air, the Ingersoll-Rand compressor being driven by electric power. Fuel oil is used in sharpening and tempering drills, a Leyner sharpener being in use. A force of 35 to 40 men is employed. The Tonopah Extension is treating an average of 136 tons of ore per day in its concentrating and cyanide plant, the ore running $15.50 per ton, the proportion of the metals being 90 oz. silver to 1 oz. gold. For September the extraction of gold reached 94.23%, that of silver 91.89%, the total extraction being 92.59%. For the same month the concentrate contained 4.85 oz. gold, and 477.02 oz. silver per ton, the recovery by concentration amounting to 20% of the total. This mill was described in the *Mining and Scientific Press* April 9, 1910, by John G. Kirchen, manager of the property. The principal change made in the process since then has been to apply the underfeed method, instead of the overfeed, to the Trent agitating tanks. The excellent mill work at this plant is under direction of J. P. Montague. The Midway mine, under the management of W. J. Douglas, has shipped 1400 tons of ore to Kennett, California, within the last six months, which sampled close to $35 per ton. The proportions of gold and silver in this ore are similar to those of the other mines of the district. A force of 35 to 40 men is employed, special attention being paid to developing and exploring. The ore shipped was taken from the 200, 300, 400, and 500-ft. levels.

The Montana-Tonopah, a résumé of the operations and production of which was published in the *Mining and Scientific Press* of October 15, is running practically the same as reported at that date.

NEW YORK

Improved Market.—Ray Central Still Statue Quo.—Butte News.—Tennessee Copper's Costs Reduced.—Cobalt Output.

A change has come over the feeling of the market. A good strong upturn, general throughout the list, carrying prices to higher levels than reached for some months, with trading running close to one million shares daily has gone far toward re-establishing confidence. The public has long been impatient of waiting for the settlement of various things which have been controlling adverse market factors. The continued improvement in copper metal forms the most encouraging feature in the mining share market. The curtailment policy is voted a success. Copper sales are increasing in volume and 13c. copper is already at hand. Mine operators and mining companies engaged in developing or working Mexican properties are jubilant over the improved outlook for silver. The industrial development of China and the comparative prosperity of India have so far increased the demand for silver as to register a quotation considerably above any price of the last two years. The unexpected action of J. Parke Channing, in advising the rejection of the option on the Ray Central bond issue held by the General Development Co., has, for the time, killed trading in the issue. So far the General Development Co. has not acted on the recommendation. Some financing has been completed by the developing 'porphyries' and an era of construction may be expected during which markets will probably be somewhat inactive. Inspiration has been one of the features in the copper list, having scored a five-point advance with a greatly increased business. The corporation has recently sold all of its treasury stock, 202,292 shares, at par, $10 per share, and has retired all of the preferred stock, leaving the concern with 1,000,000 shares outstanding, a large cash reserve ample for all immediate uses, and without any debts beyond accruing payrolls. Work on the 5000-ton concentrator is to begin at once. Ray Con. has completed its financing, sufficiently to cover all needs for the concentrator, smelter, and power plant, by the authorization of a $3,000,000 bond issue, convertible into stock at $20, to be offered to the stockholders at par. The bonds have been underwritten and all that are not taken by the shareholders have been several times over-subscribed. The new concentrator is expected to go into operation in February, 1911. The identity of ownership is so complete in the string of gigantic coppers controlled by the Guggenheims and headed by Utah Copper, that a consolidation has seemed almost inevitable, at least a merger to include Utah, Nevada Con., Ray Con., and Chino, and the two recent additions to this group, Inspiration and Mason Valley. The many conjectures in regard thereto have at length drawn a semi-

official statement from the Utah company to the effect that no merger is contemplated so long as the newer companies are still in the development stage. The Stock Exchange house of Hooley, Learnard & Co., has been prominent in the affairs of the Consolidated Arizona, which operates the smelter at Humboldt, Arizona. Changes are rumored in the directorate of this company, it is being said that W. A. Clark, J. R. Delamar, and H. C. Frick are to take places on the board. There may be some ground for the rumor so far as it concerns Clark, the Consolidated Arizona having a contract to treat part of the output of the United Verde mine. An examination is being made of the Live Oak ground at Globe, Arizona, in behalf of a Boston banking house, which is to undertake the financing of the company, if reports are satisfactory. The management claims to have proved up 10,000,000 tons of 2% copper ore by diamond-drilling. The announcement is definitely made that the new smelter of the International Smelting & Refining Co., at Tooele, Utah, is not to handle the Giroux ores, but that the latter is to be equipped with a smelter of its own and to make no attempt to begin extraction until the new smelter is ready to blow in. The new Alpha shaft of the Giroux is to be the main operating shaft of the property. The North Butte-Tuolumne controversy has been much discussed in the East the past few days. There has been strong buying in Tuolumne and an apparently authentic story that North Butte was bidding more than the market price for a controlling interest in Tuolumne. The East Butte is shipping 200 tons daily which runs better than 7 per cent.

The annual meeting of the Federal Mining & Smelting Co was held this week in New York. F. H. Brownell was re-elected president; Frank Sweeney and W. Clayton Miller, the general manager, were elected directors; succeeding Edwin Packard, vice-president, and Henry E. Cooper, retiring. The office of vice-president, is, for the present, left unfilled. Mr. Brownell said the company can pay dividends upon its preferred stock, future improvement depending upon the metal market and the result of further development and partly upon some new processes for extraction now being tested on ores of the Morning mine. The work on the Western group has been disappointing and after the expenditure of $250,000 has been almost wholly discontinued. Low metal prices last year were an adverse factor. The company has in its treasury Bunker Hill & Sullivan stock, which pays $100,800 in annual dividends. If the management decides to do extensive exploration work this fund will probably be used for that purpose.

The Tennessee Copper Co. is making a strong bid for a place in the front rank of low-cost copper producers. During the past two years the efforts of the management have been concentrated upon the perfecting of the company's sulphuric-acid plant, which is running at one-half capacity. Construction work has been completed, and the entire plant will be in operation within 90 days. The annual output is expected to reach a total of 200,000 tons and to show a net profit of $500,000; crediting this against copper costs will bring that figure down to 5c. per pound. The southern demand for sulphuric acid is increasing to such an extent that in all probability another unit will be added to the acid plant within the next two years, with a corresponding increase of copper production. The present copper output is 14,000,000 lb., but the mines can output an additional 10,000,000 lb. Tennessee is expected to resume dividends at the rate of $1.50 per share within the present year. At Cobalt a new vein has been opened parallel to the main La Rose vein, and the ore uncovered so far is estimated at $500,000. La Rose is selling for about $4.50 and not counting this recent find, is said to have about one-third of its market value in sight net. The annual report of the La Rose just issued, shows: ore shipped, 6,313,905 tons; silver recovered, 3,100,444 oz. which returned gross $1,620,341. The average price received for silver was 52.25c. per oz. Dividends paid during the year, $910,000. The suits which have been pending against the Crown Reserve of Cobalt, have been withdrawn. The Cobalt Central properties are to be sold under judicial decree by the liquidator. The sale is set for December 28.

The financial report of the Nipissing Mines Co., of October 1, shows assets of $1,344,601, consisting of cash in bank, $572,038; ore in transit and at the smelter, $315,141; ore sacked at the mine ready for shipment, $457,422.

Following the purchase of the Rea Mines, Ltd., of Porcupine, by the Consolidated Gold Fields Co., of South Africa, it is said that Barnato Brothers, of London, and J. & P. Coates Co., each have engineers in the camp examining properties. These interests, with the McArthur-Forrest people of Glasgow, make a formidable showing of British capital engaged in the development of the new Canadian goldfield.

MEXICO

Revival of Mining about Zacatecas. — El Bolanos to be Reopened. — Smelting on the West Coast.—Copala Mines Closed. — Railroad Earnings.

The foreign mining men of the Zacatecas district have organized an association, an important object of which is a revival of mining and milling in that old district, which for many years was one of the great sources of silver supply in Mexico. It is hoped to attract capital by making known the advantages and opportunities of that section and the results obtained by modern methods. The district has been dormant for a long period, but there is now promise of an awakening, and in this the organized encouragement of the foreign mining interests, as now proposed, should be an important factor. The Chapala Hydro-Electric & Irrigation Co., of Guadalajara, has plans for the transmission of power to the Zacatecas district, and with electrical power, delivered at comparatively low cost, the profitable working of old dumps and mine fillings, as well as the extensive development of old and new properties and the economical treatment of ores, will be possible. The Zacatecas Mining & Metallurgical Co., organized last year to operate the San Cristobal and Zacatecas groups, in the Zacatecas district, is completing a modern plant for concentration and cyanidation, and custom ore will be received. The 50-ton custom plant erected just outside Zacatecas, in which the State government has an interest, has not yet proved the success hoped for, and some remodeling may be done. The solution of metallurgical problems has been necessary, due to the varied character of the ore presented. The Zacatecas Syndicate, Ltd., representing the A. Goerz interests of London, has installed pumping equipment of greater capacity at the Rio Tinto, the former having proved inadequate to handle the water. The plans of this concern include important reduction facilities. A plant is being built to cyanide old tailing from the Laguna de Guadalupe, where there is a large accumulation. The Bote Mining Co. is successfully cyaniding its dump, and is rushing development in the mine. The San Roberto mine of C. A. Bentley, under development and shipping, will require a concentrating plant. Closely associated with the Zacatecas district in the days of great activity was the old Bolaños district in the northern portion of the State of Jalisco, and in that district also there is now promise of a mining and milling revival. The English syndicate that worked the Veta Grande at Zacatecas

Zacatecas, Mexico.

during the last century also operated the old Bolaños silver mines under lease, and secured big returns. Control of these mines, which are credited with a production in excess of ₱500,000,000, was recently obtained by the Bradbury interests of Los Angeles, Cal., owning the old Minas del Tajo in the Rosario district of Sinaloa. Arrangements are being made for unwatering the old workings and the extensive development of the properties. Pumping equipment has been ordered from the United States, and the road from Zacatecas to the camp is being repaired. For several years the Bolaños mines were involved in litigation between Juan B. Izabal, of Guadalajara, and the Bolaños Mining Co., of St. Louis, Mo., a $5,000,000 concern organized to acquire the mines from Izabal. Titles to the mines were obtained by Izabal from representatives of the Eagle Mountain Mining Co., an American concern formed in the 80s, which also was involved in litigation, and which accomplished very little. All the rights of the Bolaños company were purchased by the Bradbury interests, and a merger effected with Izabal. During the life of the St. Louis company practically nothing was done. The mines were flooded with the water of the Bolaños river, which was turned into the workings to put out a fire, said to have been started by the manager of the English syndicate with the object of preventing an examination by the owners. This examination was planned with a view to proving that a demand for ₱800,000 yearly for a renewal of the lease was justified by conditions. The syndicate had been paying half that sum. The mines were then producing heavily. In the San Martin de Bolaños camp, twenty miles south of the old Bolaños mines, St. Paul men will unwater and develop the Zuloaga, an antigua, owned for the last three years by Patrick Fitzgerald. In the same camp the Rosario Mining Co., organized by Pennsylvania men several years ago to operate the Rosario, Condesa, and other old mines, is starting work. The recent purchase of the Guaymas lead smelter of the Mexican-American Smelting & Refining Co. by the Pacific Smelting & Mining Co. is in line with the latter's plans for the establishment of an important custom smelting business on the west coast of Mexico. The plant will be overhauled and the facilities for the smelting of lead ores made complete. The Mexican-American Co. was a W. C. Greene enterprise, and the furnace was erected and blown in to hold a State concession for a smelter at Guaymas. After the provisions of the concession were complied with no smelting was done. The Pacific Smelting & Mining Co. through its Mexican operating concern, the Compañia Metalurgica y Refinadora del Pacifico, is actively in the market for lead and copper ores, the former for the Guaymas and the latter for the Fundición plant, and contracts are being made. Large reserves will be accumulated before the smelters are blown in. A copper-converting plant will be later installed at Fundición. All work has been stopped at the Copala mines of the Butters Copala Syndicate, in the State of Sinaloa, and G. A. Swanquist, who has been in charge, has left for the Butters properties in the Republic of Salvador. It is probable that work will not be resumed until capital for extensive development is available. Since milling was suspended last fall a limited amount of development has been in progress, and this work, it is said, has shown the existence of bodies of higher grade ore. The profitable operation of the mines depends on the opening of such orebodies, as the ore now available is too low grade for profitable treatment. When the mines were taken over by the Butters interests the market value of silver was much higher than at present. The Butters cyanide plant at the Copala mines is one of the most complete in the west coast section of Mexico, and has handled over 300 tons daily. Chas. Butters, head of the syndicate, is expected to visit the properties at an early date. The Palmilla Milling Co. will soon have the first unit of its 1000-ton cyanide plant in the Parral district ready for operation, the expectation being to place it in operation before the end of November. The mill will be able to handle from 300 to 400 tons per day. In anticipation of the early inauguration of milling, the Alvarado Consolidated Mines Co., which controls the Palmilla company, is putting the Palmilla mine in shape for production. This is the property that made Pedro Alvarado, a former mine laborer, a millionaire for a time, and the lavishness of the fortunate Mexican resulted in many stories, some of them true but others without foundation. One of the most widely circulated told of offers to pay the national debt of Mexico. In addition to treating Palmilla ores, the Palmilla company will do custom work. Another complete plant that will be soon in operation in Parral district is that of the Veta Colorada Mining & Smelting Co. This plant, which on account of company difficulties, remained in an unfinished state for some time, has been remodeled under the direction of Bernard MacDonald, of Guanajuato. It will handle 300 tons per day. The production of Parral district has shown an increase of late, the September output reaching close to 50,000 tons. The October output is expected to be over that amount. Two modern reduction plants will be soon added to the list of those operating in Guanajuato district. One is at the Tajo de Dolores mine of the Providencia Mining & Milling Co., and the other at the properties of the Tula Mining Co., at La Luz. The Providencia mill has 40 stamps, and the Tula 10. The report of operations of the National Railways of Mexico (Government merger system) for the fiscal year ended June 30, last, recently issued, shows gross earnings of ₱52,562,293.39, and net earning of ₱20,968,735.61. The net earnings for the year were sufficient to leave a surplus after payment of all operating and interest charges. But 2% for three years was guaranteed under the merger on the $30,000,000 of first preferred stock. Prior to the recent annual meeting 3% had been paid, and at the meeting an additional 1%, a total of 4%, was authorized. The gross and net earnings for the first 3 months of the present fiscal year are largely in excess of those of corresponding months of the previous year, and a much better showing is expected for the 12 months. A large percentage of the merger revenue is derived from the transportation of ores, mill products, and mine and mill equipment.

BUTTE, MONTANA

Conditions at the Anaconda.—Important New Developments.— Pending Litigation.

While there has been considerable curtailment of copper production by the Anaconda and allied companies, there has not been a corresponding reduction of ore mined nor of the number of men employed in the Butte mines. There are certain fixed charges for mining operations that cannot be reduced, and a certain number of men must be kept at work with little regard to the amount of copper produced. Advantage is taken of the necessity in employing a large force to mine a lower grade of ore and to do more than the normal amount of development. The result is that since curtailment has been in force at Anaconda properties a large amount of new work has been done, and is under way. Reports are that several large new orebodies have been opened. It is claimed by some of the officers of the Anaconda that the mines have never been in better condition and have never been better prepared to respond to a heavy demand. Development of high-grade bodies of ore in the deep levels is reported from four or five important mines. The best of these new discoveries is in the West Colusa mine of the old Boston & Montana Co., which is worked through the Leonard shaft. On the 1400 and 1600-ft. levels a large and rich body of ore has been mined and a new level has been opened on the 1800, where the same body of ore has been found, though larger and fully as high in grade as above. The Red Metal company has extended the 1800-ft. level of the Minnie Healey mine to within 40 ft. of the large new body of ore in the West Colusa and is in the same orebody. A new level has also been opened at the 2200 of the Mountain Con. mine, one of the old Anaconda group. The vein is large and of high grade. In an interview, B. B. Thayer, of the Anaconda company, is quoted as saying that the mines are looking great, and are in condition to respond to any demand that may be made on them. Considerable new work is under way, including the installation of a large air-compressor plant, with which hoisting will be done at the High Ore mines.

General Mining News

ALASKA

KETCHIKAN DISTRICT

(Special Correspondence).—The Rush and Brown mine has been unwatered and is being operated under the management of U. S. Rush. The first shipment will be made early in November. The ore goes to the Tacoma smelter.

Ketchikan, October 15.

It is reported that practically every claim on Pedro creek, near Fairbanks, is under option to the agents of an English syndicate, the purpose being to dredge the ground next summer. The ground is shallow and suited to dredging.

The report of the Alaska United Gold Mining Co. for the month ended September 15, shows that the Ready Bullion mill (120 stamps), ran 30 days, 14 hr. 56 min. Water power 1 day, 18 hr. 7 min.; steam power 28 days, 20 hr. 49 min. 700 mill (100 stamps), ran 30 days, 17 hr. 42 min.; water power 1 day, 20 hr. 10 min.; steam power 28 days, 21 hr. 32 min. Tons ore crushed, Ready Bullion mill, 20,580; tons sulphides saved, 375; estimated gross value of free gold, $26,031.46; estimated gross value of sulphides, $18,072.56; total production (R. B. mill), $44,104.02; realizable value, $41,593.71; operating expense, $27,513.61; net operating profit, $14,080.10; construction expenses, $7015.60. Yield per ton $2.14. Development work, 421 ft.; assay value $0.97 to $2.42. Tons ore crushed 700 mill, 16,474; tons sulphides saved, 300; estimated gross value of free gold, $22,615.61; estimated gross value of sulphides, $16,648,83. Total production (700 mill), $39,264.44; realizable valne, $37,238.29; operating expense, $26,585.86; net operating profit, $10,252.43; construction expense, $3721.92; yield per ton of ore milled, $2.38; development work 700-Foot claim, 231 ft.; assay value $1.14 to $3.93.

ARIZONA

GILA COUNTY

(Special Correspondence).—The total amount of work completed in driving, raising, and shaft work at the Miami mine is 75,000 ft. About 265 ft. is now being done weekly as the mine is ready for production with the exception of making a few connections between the orebody and the main haulage drifts.——Hoval A. Smith, president of the Live Oak Development Co., is visiting the property. It is estimated that the orebody as indicated by drill holes contains 10,000,000 tons of ore averaging from 2 to 25% copper. The orebody extends into the unexplored land belonging to the company 900 ft. west and 2000 ft. south of the drill holes. ——Engineers in the employ of Hayden, Stone & Co. are about to make an examination of the Inspiration mine. Mr. Hayden of that firm, and Mr. Jackling of Ray Con. are expected to visit the property soon.——A cross-cut driven southwest from the McGaw shaft of the Superior & Boston mine on the eighth level has cut the Great Eastern vein and found that oxidized ore extends to that depth. Driving on the vein has been commenced in two directions. Assays of the ore are not yet obtainable. The McGaw shaft is 907 ft. deep and will be continued. The next level will be established 960 ft. from the collar. Frank H. Probert, consulting engineer, is visiting the mine.——Operations have been resumed on the eighth level of the Arizona-Colorado mine 3½ miles northeast of Globe. John F. Shaw is conducting operations and has recently developed a vein 3 ft. wide carrying ore averaging 4% copper and 30% iron. Test shipments will soon be made to the Old Dominion smelter.

Globe, October 21.

MOHAVE COUNTY

The old Mammoth mine is being reopened and excellent ore found, according to reports. The mill is situated over the mine workings and the ground is being inspected with a view to ascertaining whether or not the ground beneath has been stoped. If not, the mill will be repaired and will soon be in operation. If it is learned that it is insecure it will be moved to a new site. The Prosperity workings have drained the Golconda mine to the 300-ft. level, and the mill is running steadily. The Wallapai King mine in Todd basin is being reopened by A. H. Smith, superintendent for the Wallapai King Mining Co. Gardner & Goodrich have sold their Kokomo group of claims near the Tom Reed, to John Levizey of Leadville, Colorado. The prospect work shows a good grade of gold ore. Recently two men took from the stope on the 200-ft. level of the C. O. D. mine, at Stockton Hill, 17 sacks of ore running $2000 per ton gold. Owing to the heavy flow of water a drift is being run at the 280-ft. level, where good ore is being taken out of a recent discovery. Through this drift the water in the old works is being lowered, and when the 300-ft. level is reached it is thought the water from the old works will have been reduced to a minimum. When the mine has been opened and connection made with the 300-ft. level a large tonnage of ore will be available and shipments will be made. The mine is more than paying all expense of development.——At the power plant in Kingman the third unit is being constructed and will give the plant a capacity of 3000 hp. under ordinary pressure and nearly 6000 hp. under high pressure. The third unit is being built with a view to adding to it with a minimum of expense in the future. Twenty-five men are working on the plant and expect to have it completed in 60 days. The company is to run new lines to the mining camps in Union pass, making a loop from the Tom Reed through Silver creek, Barton's camp, Expansion, over the Union pass, and back to Kingman by way of Coyote hill. This will give the company a circuit of all the big mines of San Francisco district and enable the properties in the isolated sections to operate at a minimum cost of power. Within the year the lines will be carried to the north, where properties are being operated with gasoline generators. The sales of power will soon exceed 2000 hp. in the San Francisco district, and fully 1000 hp. can be sold in Wallapai district.

YAVAPAI COUNTY

(Special Correspondence).—F. L. Dwight, of Los Angeles, has taken an option on the Raible mine near the McCabe, in Chaparral district and will soon begin development. Two hoists are to be placed on the property. The Leland, Mount Elliott, Little Jessie, and Little Jack mines, all in this district, are in operation.

Prescott, October 21.

YUMA COUNTY

The Paycar mines near Bouse are shipping high-grade ore to the Humboldt smelter. The Arizota company has completed a road 20 miles from Bouse to the mine. Extensive development is to be undertaken. This property is owned in the Black Hills of South Dakota. Seth Bullock, formerly president of the Iron Hill Mining Co. of Deadwood, is largely interested. Mr. Bullock recently visited the mine. Seven miles east of Bouse the St. Valentine group is being prospected with encouraging results. It is expected the first shipments of ore will be made from the Tennessee group near Bouse before November 1.

CALIFORNIA

FRESNO COUNTY

The 10-stamp mill being built for the Davis Flat Mining Co., is nearly completed and it is expected that it will be running by Nov. 15.

INYO COUNTY

(Special Correspondence).—The report of Skidoo Mines Co. for September shows 1017 tons of ore milled; value of bullion produced $22,131.17; value of concentrate estimated at $500; total production $22,631.17; time lost in mill 6 days; cost of development $887.78; of operation $7687.67; total cost $8575.45; net profit for month $14,055.72.

Skidoo, October 22.

G. H. Bradford, of Tonopah, is building a 10-ton mill at Chrysopolis, near Sniders camp, to treat ore from the old Arastra property, on which he has a lease from Dr. Woodin and William Grant of Independence. The mill will also treat custom ore. Snider's property, and Loughrie's mine adjoin the mine leased by Bradford.

KERN COUNTY

The Kern River oilfield during the month of September produced 1,035,140 bbl. of petroleum. There are 1636 producing wells in this field; 47 wells are drilling, and others are about ready to begin drilling.

MARIPOSA COUNTY

The Bullion Hill mine, near Exchequer, above Merced Falls, is said to be developed on a large acid dike that cuts the schists and slate of the region, and is gold-bearing throughout its entire width. Surface prospecting by means of cross-cut trenches every 25 ft. has shown the gold impregnation to extend for over 160 ft. along the strike of the dike. An adit is being driven to reach the dike in depth. It is in 160 ft., and, it is estimated, has about 150 ft. farther to go to reach the dike.

NEVADA COUNTY

(Special Correspondence).—The Mann hoisting engine is to be removed shortly from the Central shaft to the Cincinnati Flat mine by the North Star Mines Co. Developments at the Cincinnati Flat are progressing vigorously with good results. A more powerful engine will be installed at the Central shaft to take the place of the old machine. The 80-stamp mill is running largely on ore from Central workings.——It is rumored that a rich find was recently made at the Empire mine.——The Cassidy Con. company is arranging for the installation of heavier pumping machinery, the

Bridge Crossing South Yuba River, Nevada County, California.

present plant proving too small to handle the water. The shaft is down 240 ft. and has cut a vein of fair-grade quartz. The water is greatly retarding work.——Driving for the channel at the Jenny Lind is progressing steadily, and it is expected to reach the objective point before winter sets in. ——The rich ore-shoot recently found in the lower workings of the Pennsylvania is showing up well.——The Brunswick is idle pending the arrival of the new pumps.——George W. Root, the manager, announces that work will be shortly resumed at the Kenosha mine, in the Deadman Flat section. Sufficient funds have been raised to continue development. ——Rich ore is being extracted from the big vein at the Red Ledge mine, near Washington. The ore-shoot is several inches wide, with the quartz rich in gold. Several specimens are on display in Nevada City and Grass Valley banks. ——Payable gravel has been found in the Orient property, above Nigger Tent.——Because of lack of water for power, operations have been temporarily suspended at the Snowdon Hill mine. The adit is in 440 ft. and is expected to intersect the channel within 160 ft. As soon as sufficient water is obtainable the operation of the compressor and machine-drills will be resumed. The washing plant has a capacity of 150 cu. yd. per day. Joseph B. Martin is manager.—— The Alaska vein has been intersected 75 ft. in from the 750-ft. level. George St. John is manager.

Grass Valley, October 23.

James Accinelli, an Italian miner working in the Ancho mine, near Graniteville, drilled into a missed hole a few days since and was seriously injured.

SIERRA COUNTY

The Red Ledge mine at Scotts Valley is to be operated on a larger scale than at any time in the past. The vein is described as a great dike of ankerite with mariposite, through which occurs reticulated quartz veins—a large auriferous stockwork. It is from 60 to 200 ft. wide. Developments consist of several adits driven on the strike of the vein.

TRINITY COUNTY

(Special Correspondence).—The Headlight plant is nearing completion.——The Adams Exploration Co.'s mill will be completed about November 15.——The Golden Eagle Mine & Development Co. is installing a cannon-ball mill on its Golden Eagle claim, situated on the west fork of Copper creek.——The Siskiyou Syndicate, which now owns the Keating property on the north fork of Coffee creek, is installing a 2-stamp mill.——FitzHenry, Williams & Farnsworth have uncovered a 65-ft. vein on their North Star claim on the west end of Billy's peak. The ore is partly free milling.——Charles Crow has taken a lease on 40 acres of placer ground belonging to the Headlight company on Copper creek.——The New Blue Jay Co., owning the Blue Jay mine in Morrison gulch, has recently purchased the Morrison Gulch hydraulic mine, comprising three claims, and will get things in readiness for next winter's operations. The price paid is said to have been between $10,000 and $15,000.——It is reported that pitchblende has been found in the granite belt north of here.

Carrville, October 20.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—Work was resumed last week on the Golden Glory adit on Saxon mountain. It is proposed to drive for at least 600 ft. additional. J. F. Puchart has been appointed manager.——Operations will be resumed on the Mineral Chief mine situated on Democrat mountain. During the past week men have been employed overhauling the machinery at the 50-ton concentrating plant, while a new cable is being strung to be used as a brake for the aerial tramway. H. E. Boothe is manager.——The Santiago sampler will be ready for operation within the next two weeks. The machinery has been installed. Work of placing the machinery for the concentrating department is under way.——It is reported that the sale of the Santiago mine to the North American M. & S. Co. is pending. During the past two weeks J. H. Robeson, consulting engineer for the latter, has been sampling the property. The deal is said to be for $500,000 cash.——Work has been resumed on the New York adit situated on Pendleton mountain.—— Work was commenced two weeks ago on the Double Header adit on McClellan mountain. The property embraces 26 lode claims.——Parachine & Co., leasing on the Smuggler mine on Brown mountain, having been sending out steady shipments of high-grade ore. A streak of smelting ore is exposed 10 in. wide, which averages 500 oz. silver per ton. The vein has been opened 175 ft.——The Hollingsworth M. Co., owning the Smuggler mine, is preparing for extensive development. The shaft, down 375 ft., is to be sunk 200 ft.——The Virginia City adit on Lincoln mountain within 80 ft. will intersect the Virginia City vein, at the 500-ft. level of the shaft workings.

Georgetown, October 24.

Lessees of the Smuggler mine, near Georgetown, are shipping regularly. It is said they are breaking 10 in. of ore which samples 50% lead and 500 oz. silver per ton. The streak has been opened by drift for nearly 200 ft. Stopes are being opened. Work has been resumed on the New York adit on Pendleton mountain, to develop veins lying between the Smuggler and the Gold Belt mines. The property is owned by the Smuggler, and the veins are supposed to be the extensions of the Smuggler. A lessee on one of the lodes of the group made a shipment recently that returned 262 oz. silver per ton and 43% lead. James Beshears of Bard Creek reports the discovery of another new vein near there. He is making an open-cut on the vein across the ridge, and has a 5-in. streak of quartz liberally

sprinkled with pyrite that carries $80 per ton in gold. There is a larger streak that carries $28 per ton. Bloch & Crist, who are working the Enterprise lode on Douglas mountain under bond and lease, have driven an adit of 90 ft. and taken out ore almost the entire distance. The streak is small but the ore is of good grade.

GILPIN COUNTY

(Special Correspondence).—The Banzai mine at Black Hawk is undergoing development. A shipment of two tons of first-class ore last week returned 13.12 oz. gold and 186.40 oz. silver per ton. Boeliert & Co. are operating under lease.——The new concentrating plant on Gregory street which is being constructed to handle the dumps of the Bates Hunter mine, is nearing completion. W. S. Smith & Co. are the owners.

Central City, October 25.

It is reported that the cross-cut adit of the New Caribou mine has crossed 20 ft. of good ore. It carries gold, silver, and copper. Thus far this adit has cut 20 veins in a length of 1100 ft., but the last vein, above referred to, is the largest and best thus far. This adit is being driven 700 ft. below the old workings. The property is being re-opened by the Up-to-Date Mining Co. The Polar Star mill is crushing ore from the Gunnell mine, the ore coming out through the Newhouse tunnel. The old Kokomo mine is again being worked by local men who are themselves working in the mine. The shipments reach 80 tons monthly, mostly from the 500-ft. level. The ore runs from $20 to $30 per ton. At the Euclid mine in Black canyon, near the north line of the county, it is reported that ore assaying $16,000 per ton has been found by Henry Baer, superintendent.

TELLER COUNTY

David Daniels, timberman in the Portland mine, on Battle mountain, was struck by a falling rock, on the 22nd inst., and was instantly killed. He was at work on the 600-ft. level adjusting square sets when a slab of rock weighing about ten tons fell from the hanging wall. James Horan had his feet blown off, on the 21st inst., by a mysterious explosion in the ore-house of the Isabella mine near Cripple Creek. Although an investigation is being made it has not been learned how the accident occurred or whether or not it was the discharge of powder.

IDAHO

NEZ PERCE COUNTY

(Special Correspondence).—A complete reduction plant will be installed at the Anaconda mine, near Pierce. The machinery consists of a 7-ft. slow-speed mill with crusher and amalgamation system driven by water-power. The Anaconda has produced much ore in the last few years, and enough has been blocked out to justify the installation of the plant. A find of high-grade ore yielded more than 100 tons of rich ore, which will be the first to go through the new plant.

Spokane, October 20.

SHOSHONE COUNTY

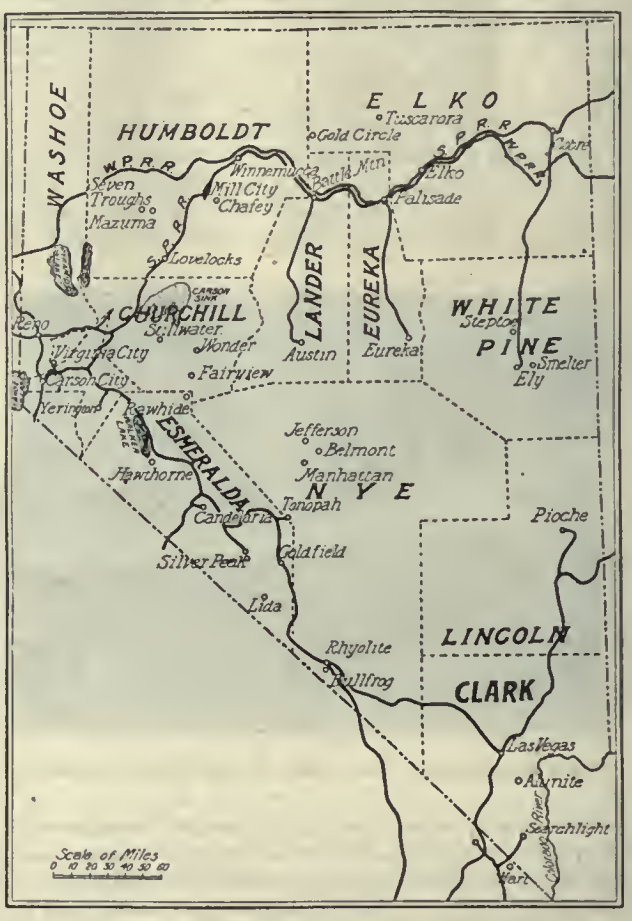
(Special Correspondence).—A car of rich ore will go from the Golden Winnie mine near Murray in a few days. It is tungsten (scheelite) and is valued at $400 per ton. The Golden Winnie is an old gold mine. The development of its tungsten deposits is a new feature.——The Coeur d'Alene Nellie mine has been reopened. In the late eighties it was one of the richest mines of the district. The ore is gray copper running from 50 oz. silver upward. For years only assessment work has been done and the workings were allowed to cave. Ore is being mined through a new adit.——The Black Sand Dredging & Concentrating Co. is working over old placer diggings thirty miles from Orofino, Idaho.

Spokane, October 21.

NEVADA

ESMERALDA COUNTY

(Special Correspondence).—The Florence mill is treating 150 tons of ore daily, which runs $10 per ton. The extraction has averaged for some time 93%, of which 30 was by amalgamation, 33 by concentration, and 30 by cyanidation. The mill-feed comprises a mixture of oxidized and sulphide ore. The concentrate is sold to Benjamin Hall, who extracts the gold and silver by roasting and chlorination at the plant of the Goldfield Cl. Mill Co., which he has leased for three years. Since Mr. Hall obtained the lease of this plant he has removed some of the original equipment and installed a mechanical roaster of his own design, which is 72 ft. long, 10 ft. wide, and provided with mechanical rabbles. At the discharge-end of the roaster the material drops into a cylinder 40 ft. in length, which revolves at the rate of 2 r.p.m. While passing through this cylinder the ore is cooled and slightly moistened, discharging into an elevator that lifts it 12 ft., where it is thrown upon a screen to remove any scraps of iron or other foreign matter, and then into bins, and thence to chlorination tanks into which the gas is introduced at the bottom. The plant



Map of Nevada.

handles 15 tons per day of concentrate, but would exceed this if crude ore were treated. F. C. Beedle is in charge of the plant. Mr. Hall is well known as having for many years been identified with similar work at Nevada City, California.

Goldfield, October 22.

(Special Correspondence).—The plant of the Nevada-Goldfield Reduction Co., operating under lease to the Goldfield Combination Fraction Mining Co., is receiving and treating 65 to 70 tons of ore per day from the Fraction mine, making an extraction of 92 to 93% by amalgamation, concentration, and cyanidation. The crushing is by stamps, the amalgamation being done on plates, and the concentration on Wilfley tables. The cyanide treatment is by the all-slime method in agitating tanks, followed by filtration of the slime in Butters filters, and precipitation of the gold in zinc boxes. The pulp passes direct from the plates to the tables on which about two tons of concentrate per day is made: all the table tailing and middling goes to a Frenier pump by which the stuff is raised to an Aikens classifier whereby the sand and slime are separated. The slime flows from this classifier to slime settlers, the sand passing to a tube-mill, the pulverized product of which also flows to the slime

settlers. Of the slime, 92% will pass 200-mesh, and all of it will pass 150. It is transferred from the settlers to treatment tanks having mechanical agitators; it is transferred again from the agitating tanks to stock tanks and thence to Butters filters of 40 leaves. C. D. Wilkinson is manager for the company; F. W. Lockman, mill superintendent; D. R. Finlayson, mill foreman. Mr. Lockman states that the assay value of the final mill tailing for July was 74½c.; for August, 53c.; for September, 59c.——The shaft at the Florence mine, which originally had one hoisting compartment and manway, within the last three months has been enlarged to three full compartments; this was effected by raising from the 350-ft. station to the surface. Then the same shaft was opened between the 350 and 500 by raising, the starting point having been obtained by driving from the 500-ft. station of the old Engineer's shaft. Each compartment is now 50 by 50 in. clear; the shaft is timbered with 10 by 10-in. sets, and lagged with 2 by 12-in. planks. Two new 2½-ton skips, one for each hoisting compartment, which are being installed, will work in balance. The skips were designed by Willis Lawrence, mine superintendent. They will dump automatically. Above each skip is a platform on which 10 men can stand, and above this is the usual protecting hood. Considerable ore from the Florence is being taken from the stopes above the 150-ft. level on the Engineer's vein. Recent work has tapped the Riley orebody on the 350-ft. level, stopes being carried up from this depth. One section of this orebody had a width of 50 ft. It is said it will average 15 ft. in width for a length of 150 ft. Stopes on the 200-ft. level of this vein are yielding a good tonnage of ore. In the course of development in Florence ground many lenses and irregular bodies of ore are found, demonstrating the erratic character of the ore occurrences.

Goldfield, October 24.

LANDER COUNTY

The True Blue tunnel in New York canyon has been equipped with a compressor of 600 cu. ft. capacity. It is driven by a 75-hp. gasoline motor. The compressor plant is situated opposite the portal of the adit. In driving the adit 12-lb. T rail was used. This has been replaced by 16-lb. rail. Among other new equipment are 15 steel ore-cars of 20 cu. ft. capacity. Three shifts are working in the face driving the adit toward the Patriot mine, which will be reached 3650 ft. from the mouth. The adit is being run on the Patriot-Chase vein, which is already credited with a production of $5,000,000. The mines producing this were the Patriot, Morrison-Cable, Chase, Annie, and True Blue. These are now owned or controlled by the Maricopa company. It is claimed that the dike which forms the foot-wall of the vein carries from $3 to $40 per ton gold. The dike is from 80 to 100 ft. in width, and many samples taken from it show the presence of gold in varying amounts. A mill of 100 tons capacity was recently bought at Denver, which will soon be erected. The metallurgical process to be employed is a modification of the practice at the Tonopah mill at Millers.

NYE COUNTY

(Special Correspondence).—The Volcano group of claims, 16 miles northeast from Tonopah, is under bond to George Wingfield, who has a small force at work developing. Some ore is being sacked. W. B. Morris is in charge.——The Round Mountain Mining Co. is mining and milling 3000 tons of ore per month, and recovering on amalgamating plates from $35,000 to $40,000 per month in bullion.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The Ernestine Mining Co. has the pipe-line completed, with water flowing into the mill by gravity. On Oct. 15 the plant started, dropping 30 stamps; work is in full force in both mine and mill. The eleventh level east has developed some rich ore; work is being pushed in 17 west.——The Treasurer Mining & Reduction Co. has let a contract for hauling 50 tons per day from the mines to the mill on Whitewater creek. A crew is erecting a transmission line from power-plant to the mines. Two shifts are at work in the mine, timbering and preparing for ore extraction. At the Deadwood mines the shaft has been timbered to the 500-ft. level and sinking continues. Mill construction is progressing rapidly, with daily arrivals of machinery and supplies. Work has been started on a pipe-line, two miles in length, to furnish water for milling and domestic purposes. Lime kilns are also being erected.——At the Socorro mines contractors started sinking the 3-compartment vertical shaft below the 620-ft. point on Oct. 14. This is the most important work to the district in progress at present.——On the adit level of the Enterprise mine, a cross-cut is being run into the foot-wall dike and the Perseverence shaft is being retimbered.——High-grade ore was discovered in performing the annual assessment on the McKinley mine.——A cross-cut driven east from the main level on the Leap Year encountered the Malachite vein carrying good ore. The east drift on the Little Charlie continues in excellent ore. The three boilers at the Cooney mine are in shape for use. Grading for the new assay laboratory has been started.

Mogollon, October 21.

TEXAS

(Special Correspondence).—There is more prospecting and development going on in the Shafter silver mining district of Presidio county than for many years. It is stated that good ore is being found in some of the claims. The Silver Hill Mill & Mining Co., which was recently organized, has taken over a section of mineral land that was formerly operated by the Cibolo Mining Co. It adjoins the rich mine of the latter company at Shafter. The mine that the Silver Hill Mill & Mining Co. has acquired has a good producing record, its ore in the past having been treated at the Cibolo Mining Co.'s mill. It is announced that the new company will install modern machinery and begin an extensive system of development. The company has its headquarters at Marfa, which is the nearest railroad point to the mine, being 48 miles distant. It is reported that the construction of a railroad from either Marfa or Alpine to the Shafter mineral district is under consideration by those who are interested in mines in that district.

Alpine, October 22.

WASHINGTON

FERRY COUNTY

(Special Correspondence).—Stockholders of the Republic Mines Corporation received a dividend of $15,000 October 15. This brings the dividends up to $70,000 from a corporation ranking among the youngest in the State of Washington. The source of this profit is a vein from 3 to 15 ft. wide in the Lone Pine-Surprise mine in Republic district. Sixty cars of ore were taken out of this body during the month. Assays run from $15 to $150 gold per ton. While operations have been confined to a depth of 150 ft., an adit has been started that will open the shoot at 400 feet.

Spokane, October 20.

KITTITAS COUNTY

(Special Correspondence).—Directors of the Glacier Peak Mining Co., of Roslyn, Washington, are reported to have declined an offer of $500,000 for its copper mine in Lake Chelan district, northwest of Spokane. It is said that the offer came from the Guggenheims, representatives of whom examined the property following the report of an important discovery. Officials say that a large reduction plant will be installed, the ore being rich enough to insure profit from the start. The company is composed of ten residents of Roslyn, who have expended a large amount of money in development during the last two years.

Spokane, October 20.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—An option has been given on the Vancouver group, Sheep Creek, to C. H. Harvey, of Nelson, who will interest Spokane capital in the property and do work. A tunnel has been driven 70 ft. on the vein and three cars of ore shipped with gratifying results.——The Wilcox mine at Ymir is getting out a car of concentrate to be shipped to the Trail smelter. The compressor for the Dundee mine is being installed. Part of the 5-stamp

mill for the Joker property near Kaslo is being erected. The concentrator at the Cork mine is running steadily. It is expected that the Rambler-Cariboo will be shipping again in a couple of weeks by way of Three Forks. There is a rumor, however, that the Government at Victoria has arranged with the Great Northern for the rebuilding of the Kaslo & Sandon railway.——The shipments of ore and concentrate from the Slocan-Kootenay mining district for the week ended October 15 and for the year to that date were as follows:

Mine.	Week, tons.	Year, tons.
Highland (concentrate)	71	241
Molly Hughes	34	326
Richmond-Eureka	59	3,371
St. Eugene (concentrate)	150	11,826
Sullivan	838	15,962
Yankee Girl	85	4,251
District milling operations	4,000	205,400

(Special Correspondence).—While shipments from the mines of the Granby Con. M. S. & P. Co. have been light during the past few weeks, it is now announced by Mr. Graves, the manager, that hereafter the smelter will be run at full capacity, which will mean shipments from the mines of 18,000 to 28,000 tons per week. The company is considering the development of a water-power it owns on Kettle river. ——The working force at the Mother Lode mine of the B. C. Copper Co. is to be augmented and the output raised to 1500 tons per day. The second enlarged furnace is in operation at the Greenwood smelter. The profits of the British Columbia Copper Co. for August amounted to $34,625. The cost of producing copper was 7.7c. per pound. Mr. McIntosh, the manager, has returned from Chicago and reports that work will be resumed on the Greenwood-Phoenix tunnel with 20 men.——The shaft of the Midway coal property, owing to water trouble, is not being worked at present. A cross-cut is being driven on the seam. Work is progressing on the Combination property. The shaft is down 100 ft. A cross-cut is to be run to the ore-shoot, 30 ft. distant.—— The shipments of ore from Boundary district for the week ended October 15 and for the year to that date were:

Mine.	Week, tons.	Year, tons.
Granby mines	13,646	892,339
Jackpot	329	10,193
Mother Lode	9,503	283,758
No. 7	31	104
Rawhide	2,800	6,700
Snowshoe	2,131	125,093

Phoenix, October 21.

With the success of the Mayflower and Blue Bird mines this season the owners of the Hill Top property in the South Belt have been encouraged to begin a thorough system of prospecting their property. This is to be undertaken promptly, and will likely be followed by active development, as the Hill Top property has the Mayflower vein.——The report of the Dominion lead-bounty commissioner shows that an increase has been made in shipments of lead to the Trail smelter and refinery for the month of September over previous months. The following table gives the month's production:

Mine.	Weight ore, lb.	Lead, lb.
Blue Bird (Rossland)	48,667	2,095
Bismark	34,623	1,731
Emerald	344,484	122,326
Enterprise	46,165	15,142
Eastmount	135,668	18,092
Ferguson	56,769	11,524
Fidelity	663	263
Hewitt	42,985	3,095
Highland	132,061	79,498
Idaho-Alamo	142,234	39,056
Molly Hughes	63,556	572
Noonday	29,497	9,999
Mayflower	38,081	990
Ruth	140,893	80,393
Standard	399,072	283,460
Slocan Star	172,890	56,114
Yankee Girl	744,825	19,839
Van Roi	211,395	125,995
Widdowson	2,348	89
Richmond-Eureka	626,147	96,991
Sullivan	7,251,890	1,352,586
St. Eugene	1,183,394	716,034
Total	11,848,307	3,035,884

Nelson, October 22.

(Special Correspondence).—The ore shipments from Rossland district for the week ended October 15 and for the year to date were as follows:

Mine.	Week, tons.	Year, tons.
Centre Star group	3,730	147,357
Le Roi No. 2, Ltd.	557	23,768
Nickle Plate	67	617

Rossland, October 21.

ONTARIO

(Special Correspondence).—Frank C. Armstrong has returned to New York after an inspection of the Porcupine district and an examination of the Armstrong-McGibbon properties. On this group in North Tisdale the main vein has been shown at various places for a distance of 630 ft. At the eastern end a shaft has been sunk 14 ft. At the bottom of the shaft gold shows in five places. West of this 140 ft. a test pit sunk on the vein shows much gold, and 496 ft. to the west of the test pit an area 20 by 60 ft. also shows free gold. Mr. Armstrong has given instructions to strip the vein the entire distance and to sink two shafts, one at the eastern end and one at the western end of the outcrop. Camp buildings are being constructed and roads built to the property.——H. C. Collins, of the Porcupine Gold Ridge Mines Co., left Haileybury on October 15 to inspect work which has been done on the properties of his company in Porcupine. Reports at the New York office of this company state that two new veins have been found on the south end of the property near the north shore of Giliies lake. These veins are both well defined and assay $48.50 and $56 respectively, the samples being taken with care across the vein. On vein No. 1, assays as high as $320 per ton have been taken from rock showing no visible gold. The main shaft has reached a depth of 50 ft. where a cross-cut has been started to the vein. Stringers have already been cut in this cross-cut which show gold. It is said machinery will be brought in this winter and that the working force will be increased as soon as supplies can be obtained at reasonable cost.

Porcupine, October 17.

MEXICO

SONORA

L. R. Budrow, superintendent of the El Tigre mine, says that construction work on the new plant at the El Tigre is progressing and that between 500 and 600 men are employed in the mines, mill, and on construction work. All the foundations and cement work for the additional buildings and machinery have been done and considerable machinery has arrived. It is expected that by May 1, 1911, the new plant will be ready to put into operation, driven by electric power which is to be transmitted from the Copper Queen smelter at Douglas, Arizona.

CHIHUAHUA

The September report of the Rio Plata Mining Co. shows net returns on shipments $50,463.07 U. S. currency; mill crushed 1934 dry tons ore, containing 80,769 oz. silver gross; produced 21.2 tons concentrate; cyanide plant treated 2086 tons tailing containing 74,460 oz. silver gross; recovered in concentrate 21,721 oz. silver; recovered in bullion by cyanide 62,121 oz. silver; total silver recovered 83,842 oz.; value of silver recovered $43,300.51 U. S. currency; profit on store $281.10; total income $43,581.61; operating expense $16,062.57; operating profit $27,519.04.

GRINDING WHEELS—GRINDING MACHINERY—GRINDING. By C. H. Norton. Proceedings Colorado Scientific Society. Pp. 25. Illustrated.

MINERAL STATISTICS OF PERU, for the year 1908. By C. P. Jimenez, statistician. Bull. No. 76, of the Department of Mines (in Spanish).

MINING OPERATIONS IN THE PROVINCE OF QUEBEC, for the year 1909. By T. C. Denis, Superintendent of Mines. A bulletin of the Department of Conolization, Mines, and Fisheries. Pp. 32. Illustrated.

PROGRESS OF THE MINERAL INDUSTRY OF TASMANIA, being the report of the Secretary of Mines for the year ended June 30, 1910. This publication of 16 pages is statistical, and gives much information in condensed form.

OUTLINE INTRODUCTION TO THE MINERAL RESOURCES OF TENNESSEE. By George H. Ashley, being an advance chapter of Bulletin No. 2, on the Mineral Resources of Tennessee. Issued by the State Geological Survey of Tennessee.

INFORMES Y MEMORIAS DEL INSTITUTO MEXICANO DE MINAS Y METALURGIA. (Transactions of the Mexican Institute of Mines and Metallurgy) for June, 1910. By E. Girault. This deals chiefly with the San Rafael y Anexas, at Pachuca.

FOREST FIRES IN NORTH CAROLINA, being Paper No. 19, of the North Carolina Geological and Economic Survey. By J. S. Holmes, Forester. Pp. 52. Ill. This bulletin gives some valuable information concerning forest fires and means for their control.

SOME ORE DEPOSITS IN MAINE AND THE MILAN MINE, NEW HAMPSHIRE. By W. H. Emmons. Bull. 432, U. S. Geol. Surv. Pp. 60. Index, maps, and sketches. Gives a description of the mineral deposits and their exploitation in the region indicated by the title.

GEOLOGICAL MAP OF COBALT. By W. G. Miller and C. W. Knight. The Ontario Bureau of Mines has recently issued the fourth edition of the geological map of Cobalt, Ontario, on a larger scale than the earlier editions. The map includes some areas not formerly appearing on any map.

ESTADISTICA MINERA DE CHILE EN 1908-1909. By Guillermo Yunge. Pp. 696, Ill. Santiago, 1910. This volume is issued by the Sociedad Nacional de Minera, and contains a vast amount of information relative to the mining industry of Chile, including descriptions of the mines of gold, copper, iron, and the various deposits of nitre and other mineral salts of commercial value. Besides the above there are extensive chapters on the metallurgy of the various metallic minerals, as practised in that country. The figures of production given in this volume were summarized in the MINING AND SCIENTIFIC PRESS, May 28 last.

TWENTY-EIGHTH ANNUAL COAL REPORT OF THE ILLINOIS BUREAU OF STATISTICS FOR 1909. By David Ross, secretary. Pp. 487. Springfield, 1910. This volume is Mr. Ross' usual complete exposition of the coal-mining industry in the State of Illinois, and treats the subject in great detail, with much statistical information relative to tonnage output, number of men employed, mining and haulage methods, relations of coal-mining industry to railroads, and much other valuable information. The total output for the year is given at 49,193,710 tons; the total number of mines, 886; shipping mines, 384; the latter produced 47,958,562 tons with an average working time of 189 days and an average value of all grades of ore at the mine of $1.012 per ton.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

KENT'S MECHANICAL ENGINEERS POCKET BOOK, 8th edition. $5. John Wiley & Sons, New York.

The new volume has been completely revised and brought up to date. It contains over 300 new pages, found necessary to accommodate the new engineering data. The entire work has been re-set, the tables revised, and the volume improved in many ways.

SEWAGE DISPOSAL. By Leonard P. Kinnicutt, C. E. A. Winslow, and R. Winthrop Pratt. Pp. 436. Ill. $3. John Wiley & Sons, New York; Chapman & Hall, London.

This book discusses fully the fundamental principles of chemistry and bacteriology involved, as well as the engineering features incidental to sewage disposal. It will be very useful to the student who has taken up this important branch of engineering and also to those officials who are identified with the health department of cities.

ECONOMIC GEOLOGY, with special reference to the United States. (Third edition.) By Heinrich Ries, professor of Economic Geology at Cornell University. Pp. 589. Maps and Ill. $3.50. The Macmillan Co., New York.

The work has been completely revised and enlarged. It deals with almost every phase of economic deposits in the United States, with a great many beautiful and instructive illustrations. The fact that this is the third edition of this work within four years is an indication of its value and popularity.

MINES OF AFRICA. (Seventh edition.) By R. R. Mabson. Pp. 775. Maps. $6. The Statist, 51 Cannon street, London, E. C.

This annual publication formerly issued under the title 'Mines of the Rand,' now has been compiled to include the mines throughout Africa, its purpose being to give information, taken from official reports and other reliable data, relative to mines throughout Africa. The new volume, 1910-11 adds particulars regarding mines of the West Coast and of Rhodesia. The maps are a feature of the book.

ELEMENTARY CRYSTALLOGRAPHY. By W. S. Bayley. Pp. 241. Index. Ill. $2. McGraw-Hill Book Co., 239 W. 39th street, New York.

This volume has been prepared in view of the increasing interest in the science of crystallography, in connection with the study of mineralogy. The author in his endeavor to supply something which would be of value to the student of crystallography—simplifying the science as far as possible—has succeeded admirably. The subject is presented in an attractive manner and the illustrations are particularly good. It is a work every student of mineralogy should own.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

W. L. B., Gage, New Mexico: Diabase.

E. L. B., Carville, California: Yellow garnet.

J. S. H., Quincy, California: Quartz with brown garnet.

P. E. M. Co., Johnsville, California: Quartzite with soft serpentinized matter.

F. W., Conejo Blanco, Mexico: No. 1, Orthoclase porphyry; No. 2, andesite dike rock; No. 3, altered volcanic rock; No. 4, contact phase of an andesite or orthoclase porphyry.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

OPTION FOR PURCHASE OF MINING PROPERTY—ESTOPPEL

A land owner giving a written option for the purchase of mining property, and which recited a sufficient consideration, was estopped to deny the receipt of such consideration as against one who with his knowledge and without objection on his part purchased such option and paid substantial consideration therefor.

Horgendorn *v.* Daniel, 178 Fed. 765, May '10.

STATE REQUIREMENTS AS TO LOCATION OF PLACER CLAIMS

The statute of Colorado requiring the discoverer of a placer claim in order to complete his location, to post thereon a notice containing the names of the locators, and to mark the surface boundaries with substantial posts sunk in the ground at each angle of the claim, requires a locator to sink posts into the ground whether the location be on unsurveyed government land or on surveyed lands. And such requirement does not conflict with the United States statute providing that where placer claims are on surveyed lands and conform to legal subdivisions no further survey or plat shall be required, as this provision refers only to the plat and survey required to be filed on applications for patents and has no reference to location.

Saxton *v.* Perry, (Colo.) 107 Pac. 281. Feb. '10.

APPROPRIATION OF MINERAL LAND FOR RIGHT OF WAY—DAMAGES

Where a railroad company proceeded to condemn a right of way for its road over a large tract of land containing a valuable vein of coal, and where such right of way was along the base of the hills and which separated the hills containing the vein of coal from the only level portion of the land, available for the erection of a proposed plant to conduct mining operations, including tipples, shafts, side tracks, etc., the land owner was entitled to prove, as part of his damages, the lessened value of the level tract by reason of its being severed from the hill portion by the road, and that the entire tract must be considered as coal land.

Patterson *v.* Iaeger & Southern Ry. Co., 178 Fed. 649, April '10.

ACTION TO DETERMINE RIGHT TO PUBLIC MINING LANDS—IMPROVEMENT WORK

In an action to quiet title to mining claims an instruction was correct which informed the jury that if the requisite work was done upon one claim, the title to which was not in issue, and such work was done in pursuance of a system that tended to a development of the claims owned or claimed by the plaintiff in action, such work was sufficient to prevent a forfeiture of any such claims, where it was shown that the claim on which the work was done was an adjoining claim, and the law is that work done upon any one of such claims can be applied to any of the others. An instruction was correct which also informed the jury that work outside the limits of a claim must be such as has a tendency to benefit or develop the claim and that the burden of proof was upon the defendant to show that the necessary work was not done as required by law, but that the burden was upon the plaintiff to show that any work done outside of the claim must be for the benefit or for the development of the claim. In such an action the law requires clear, convincing evidence to effect the forfeiture of a claim duly located and worked in good faith, and the evidence must satisfy a jury by a clear preponderance thereto that the plaintiff failed to perform the necessary work before a forfeiture will be permitted. So whether work done on a mining claim is such as to benefit or develop other claims and so satisfy the requirement of the law as to development of such claims is a question of fact.

Big Three Mining & Milling Co. *v.* Hamilton, (Cal.) 107 Pac., 301. Jan., '10.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HENRY HANSON is in San Francisco.

E. B. KIRBY is in British Columbia.

FRED T. WILLIAMS is at Coalville, Utah.

F. W. DEWOLF was at Pittsburg last week.

W. H. WILEY has gone to Peru for three months.

GEORGE H. DERN was in San Francisco this week.

E. H. BENJAMIN has gone to Hayden Hill, California.

C. J. HUTCHINSON has gone to Eldorado county, California.

T. LANE CARTER is in Mexico making mine examinations.

J. E. SPURR recently spent some time at Tonopah, Nevada.

ROSS B. HOFFMAN has gone to Montana to examine mining properties.

W. E. THORNE has returned to San Francisco from Dawson, Yukon Territory.

H. ABBOTT TITCOMB is at Newton, Massachusetts. He will return to London soon.

J. H. BAKER and R. B. HEGARDT have returned to Oakland, California, from Mexico.

VICTOR E. TOLL, of Seattle, is at the Palace Hotel in San Francisco for the winter.

ARTHUR L. PEARSE has gone to Juneau, Alaska. He will be in San Francisco November 12.

W. M. KNOX is in London returning from Brazil. He will reach San Francisco about December 1.

R. H. TOLL, of Denver, was in Kansas City last week and has gone to Arizona on examination work.

ARTHUR K. ADAMS has left Cheyenne, Wyoming, and is now at the General Land Office, Helena, Montana.

BERNARD BRUHN was in San Francisco this week on his way home to Honolulu from Plumas county, California.

EMERSON GEE has been examining mining properties at Chloride, Arizona. He returned to Los Angeles October 25.

DONALD FERGUSON, of Goldfield, Nevada, spent several weeks in Sinaloa and Sonora, Mexico, on mine examinations.

W. G. ANDERSON, recently with the Cia. Minera La Republica Suaz, Chihuahua, Mexico, is now at 220 Parnassus avenue, San Francisco.

E. S. BASTIN and J. M. HILL have left Central City, Colorado, for Washington, D. C., having completed their season's studies of the geology of Gilpin county.

COREY C. BRAYTON has taken a position as superintendent of the rock-crushing department for the Natomas Consolidated. He will make headquarters at Sacramento.

Among the members of the American Institute of Mining Engineers sailing from New York October 21 for the Canal Zone were: D. W. BRUNTON, R. W. RAYMOND, J. W. AILES, THOMAS BROWN, F. L. CLERC, H. S. DRINKER, C. W. GOODALE, H. W. HARDINGE, HENNEN JENNINGS, WILLIAM KELLY, WILLIAM KENT, CHARLES KIRCHHOFF, W. A. LATHROP, A. F. LUCAS, R. V. NORRIS, E. W. PARKER, H. C. PERKINS, J. W. RICHARDS, D. M. RIORDAN, D. B. RUSHMORE, W. L. SAUNDERS, J. M. SHERRARD, JOSEPH STRUTHERS, A. E. VAUGHAN, DAVID WILLIAMS, GARDNER F. WILLIAMS, and THOMAS D. WOOD.

A TRANSLATOR with a knowledge of German, French, and Spanish, is wanted by the U. S. Bureau of Mines. Applicants should send to the U. S. Civil Service Commission, Washington, D. C., for Forms 752 and 1312.

JUNIOR ENGINEERS are wanted by the U. S. Bureau of Mines and an examination will be held by the U. S. Civil Service Commission November 22-23, to form an eligible list. Candidates should apply to the Commission at Washington, D. C., asking for Forms 757 and 1312.

Company Reports

TEWKSBURY AMAL. GOLD DREDGING CO.

Two semi-annual reports of the Tewksbury Amalgamated Gold Dredging Co. of Australia afford some interesting data on the cost of dredging in that region. The Tewksbury properties are situated in northeastern Victoria, along the Ovens and Buckland rivers, near the village of Bright. The company employed five dredges in its operations during the first six months of 1908, and the first half-yearly report of H. S. Eyton, the manager, shows that these five machines during six months dredged an area of 42 acres, moving 1,056,051 cu. yd. of earth, recovering 4395 oz. 19 dwt. of gold, which was sold for £17,817 5s. 7d., an average of 4.049d. (about 8c.) per cu. yd. The working costs during the same period were but 1.714d. (3.428c.) per cu. yd., a remarkably low cost for dredges of such relatively small capacity, the average daily yardage for the five dredges being only about 1460, which is about one-half the capacity of the larger type of dredges of California. The depth of gravel in the various pits ranged from 13 to 21.3 ft. Individually the dredges vary in capacity during the period mentioned from 58.3 to 71.2 cu. yd. per hour.

During the half year ended June 30, 1909, the performance of these five dredges was somewhat less satisfactory, the acreage being larger, and the number of cubic yards being 1,181,609, as against 1,056,051 in the first half of 1908. The gold yield in the first half of 1909, however, was but 3341.3 oz., as compared with 4395 oz. 19 dwt. for a similar period in 1908, while the working costs were increased from 1.714d. per yard in 1908 to 1.758d. (about 3.51c.) in 1909. The real cause of this increase in cost of operation is not apparent from a study of the figures of the report, further than that there was an increase in expense in nearly every department, though the increase in cost is particularly noticeable in the item of renewals and repairs to dredges during the later period, which was to have been expected. The dredges at Bright are of the ordinary open-connected type, and the work was done on alluvial flats under favorable conditions.

The following table gives the costs of dredging operations at the Tewksbury company's property for the two periods mentioned:

	Total, 1908.	Average per dredge.	Total, 1909.	Average per dredge.
Time worked, hours	16,476	3295	16,551	3310
Area dredged, acres	42	8.4	47.49	9.5
Average depth, ft.	16	....	15.4	....
Turnover, cu. yd.	1,056,051	211,210	1,181,609	236,322
Turnover, per hour	....	....	71.4	....
Gold won	4395 oz. 19 dwt.	879 oz. 4 dwt.	3341.3	668.3
Gold won, per acre	104 oz.	....	70.4	....
Gold won, per week	169 oz.	33.8 oz.	132.3	26.4
Gold won, value	£17,817 5 7	£3563 9 1	£13,521 4 0	£2704 4 10
Gold won, value per cu. yd.	4.049d.	....	2.746d.	....
COSTS				
Wages and salaries	£4404 8 4	£880 17 8	£4694 3 8	£938 16 9
Wages and salaries, cost per cu. yd.	1.001d.	....	0.954d.	....
Repairs and renewals	£855 13 10	£171 2 9	£1413 1 3	£282 12 3
Repairs and renewals, cost per cu. yd.	0.194d.	....	0.287d.	....
Firewood	3088 cords	617 cords	3657	731
Firewood, per week	118.9 cords	23.7 cords	140	28
Firewood, cost	£1533 8 3	£306 13 8	£1775 10 10	£355 2 2
Firewood, cost per cu. yd.	0.348d.	....	0.360d.	....
Other costs	£646 14 10	£129 7 0	£771 0 1	£154 16 0
Other costs, per cu. yd.	0.147d.	....	0.157d.	....
Total working costs	£7540 5 3	£1508 1 1	£8656 15 10	£1731 7 2
Total working costs, per cu. yd.	1.714d.	....	1.758d.	....
Total working costs, per oz. of gold	£1 14 4.2	....	£2 11 9.8	....

A comparison of costs of dredging must necessarily be unsatisfactory unless every condition in each instance is known. W. H. Shockley supplied figures on the cost of dredging in Siberia, in which he stated that in the Urals the cost per cubic yard was from 6.5 to 9c. and on the Yenisei it ranged from 8.5 to 11.5c. per cu. yd. In California, at one property, near Oroville, the average cost in dredging loose gravel with a bucket of 3½ cu. ft. capacity during a period of six years averaged 7.991c. per cu. yd., and another dredge, operating in tight gravel with buckets of 5 cu. ft. capacity during four years did the work at a cost of 9.947c. per cubic yard.

BROKEN HILL PROPRIETARY COMPANY

The semi-annual report of the Broken Hill Proprietary Co., of New South Wales, for the half-year ended May 31, 1910, shows unusual disturbance of operations, due to various causes, but principally to difficulties with coal supply due to a strike of coal miners. The zinc concentration plant was idle ten weeks of the time, while smelting operations were reduced to two furnaces, owing to inability to obtain sufficient fuel. The gross profit for the half-year amounted to £46,047 9s., which, after deducting £8183 2s. 1d. for depreciation, left a net profit of £37,864 6s. 11d. The total silver output was 2,004,702 oz., inclusive of ores purchased and zinc concentrate sold. Soft lead produced, inclusive of the product of purchased ores, was 31,135 tons. During the period covered by the report no work was done underground except a few repairs to timbers. There was treated in the lead concentration plant 126,700 tons of ore taken from old tailing dumps. At the zinc concentration plant 103,792 tons of ore was treated.

HOMESTAKE MINING CO.

The report of this company for the year ended June 1, 1910, shows that despite the discontinuance of work November 24, 1909, to January 9, 1910, 1,824,623 tons of ore were broken in the stopes, and 157 ft. of raises, 14,239 ft. of drifts, and 35 ft. of shaft, were excavated. The bullion receipts were $4,498,751.11, being derived from the milling of 1,237,381 tons of ore; an average return of $3.63 per ton. The principal improvement work of the year was in connection with the Spearfish creek hydro-electric plant. Expenditures on this amounted to $282,044, and T. J. Grier, superintendent, states that 82% of the 24,000 ft. of tunnel was excavated and that the intake dam is well under way. Total receipts for the year, including a balance June 1, 1909, of $677,339, amounted to $5,298,623. Dividends to the amount of $982,800 were paid, taxes amounted to $106,990, and the balance at the end of the year was $481,748. Mr. Grier estimates that the ore blocked but not broken is sufficient to supply the 1000 stamps of the company for twenty years.

HISTORY OF THE WATER LEYNER DRILL

By Charles A. Hirschberg

Any history of the rock-drill would be incomplete without mention of the Water Leyner drill, which marks a great advance in rock-drilling. There is no questioning the debt the mining industry owes to the invention of the reciprocating or piston type of rock-drill. The first drill brought out by J. George Leyner, in 1895, was of the reciprocating piston type. Being, however, of a progressive and inventive turn of mind, he was not satisfied with this type of drill, but began experimenting with drills involving the principle of the hand-hammer blow. He soon became convinced that this was the correct ideal for rock-drilling, since the whole energy of the blow could be imparted to and through the drill steel and cut the rock, and not wasted on inertia and friction. In the Leyner drill the only moving part is the hammer. This construction gives a weight that is light and constant at all times, permitting lighter construction and greater drilling speed. The correctness of this principle is generally admitted. Other inventors had previously experimented with drills of the hammer type, none of which, however, proved successful commercially. Mr. Leyner is, therefore, the pioneer in the advocacy, invention, and sale of drills constructed on this principle, which has proved successful. The first hammer drill which he produced did not embody the water feature, but, realizing the value of cleaning the holes from the rock cuttings while drilling, and, as the dust created by passing air alone through hollow drill steel to the cutting point prohibited the use of the drill as then constructed, he conceived the idea of passing air and water through the drill steel to the cutting point. This is very important to the mine manager, for the reason that it results in ejecting the rock cuttings during the process of drilling so that the steel is cutting virgin rock with every blow. Further, the fact that the dust is allayed at the same time, improving underground sanitary conditions, is receiving the attention of governments, notably that of the British government, particularly in South Africa and in Australia.

The first model of the Water Leyner drill was brought out in 1898 and demonstrated the value of the hammer principle as well as the water feature. The attention of Mr. Leyner has since been devoted to simplifying and strengthening the means of utilizing these two features. In late models, new appliances of utility and convenience have been added, one of which is an automatic oiling device. The importance of this is apparent, for rock-drills, more than any other class of machinery, are subjected to not only abuse, but to passive inattention and neglect as well. This device insures proper, automatic, continuous lubrication of the drill without any attention from the operator. The air-throttle, unlike that of other drills, is placed in a taper seat formed in the drill cylinder casting. This is automatically pressure-packed and consists of two parts, a handle and valve, while its location is both convenient and safe. Another important feature of the Water Leyner drill is that it permits of the use of an improved system of pointing drill holes, which, when charged with explosives and fired, break the ground more effectually than by other systems. The term 'Leyner cut' as applied to a round of holes has come into general use on account of the many upper or dry holes which can be drilled to advantage only with this drill. From the fact that the drill holes can be pointed exactly as they should be, without regard to angle, direction, or condition of the face, and are not limited in position by the unwieldiness of the machine, much less powder is required and the same breaking effect can be obtained with fewer drill holes of smaller diameter. It is possible with Leyner drills to carry out accurately every time, any system of holes that may be devised for breaking the rock to the best advantage. In other words, a hole can be started wherever desired and bottomed accurately at a predetermined point. The Leyner drill has reached such a point of efficiency that today it holds the three best American tunnel-driving records, not alone for drilling speed, but for cost per foot.

TABLE OF CONTENTS

EDITORIAL

IRON ORE shipments from the Lake Superior district are estimated at 44,400,000 tons this year, equivalent to about five per cent increase over the output for 1909.

MEXICAN mining properties must be properly surveyed and marked by monuments before next January. Fine and loss of property is the penalty for neglect to make the surveys. Mine owners would do well to take prompt action in the matter.

LOSS due to the recent fires in National Forests in Montana and Idaho is estimated to have amounted to six billion feet of timber. The gross value is put at $15,000,000. How much of this amount can be saved by sale of fire-killed timber is uncertain but the Forest Service is endeavoring to interest lumbermen by offering the stumpage at greatly reduced prices.

PORCUPINE continues to make a good showing. One of the things which augurs best for the new Canadian goldfield is the substantial character of the men who are taking hold of its development. With the Canadian Copper Company controlling the Dome, and the Consolidated Gold Fields of South Africa, Ltd., acquiring the Rea, the mines are sure to have both ample capital and excellent professional direction.

AN AMBITIOUS plan to generate power in the Grand Canyon of the Colorado by means of a dam 700 feet high, is under discussion. The difficulties in the way of building and maintaining such a dam without danger to the people below would be immense and may well prove insurmountable. Until, therefore, some adequate discussion of the technical problems involved is available, the project need not be taken seriously.

NEW ZEALAND is to entertain the members of the Australasian Institute of Mining Engineers January next. The Institute will assemble at Auckland January 25 and visits will be made to the Thames, Waihi, Karangahake, and Waikato districts, as also to the Rotorua Hot Springs. Extensive preparations for the meeting are being made and we can safely congratulate in advance the engineers who may find it possible to attend.

CONGRESS adopted last session a curious provision to the effect that items in an appropriation bill, as agreed on in committee, are not to be made public except as the bill is read on the floor of the House. Since an item once read is not subject to a point of order and members can not pos-

sibly know what is in the item until it has been read, the practical effect will be to increase greatly the already large power of the appropriations committee.

DESERVED honor has come to Mr. C. E. Munroe, who has been made president of the section on explosives of the eighth International Congress of Applied Chemistry, which is to meet at Washington, 1912. Mining men know Mr. Munroe mainly as the one who organized the investigations of explosives now being carried on for the United States Bureau of Mines by one of his students, Mr. W. O. Snelling. Aside, however, from this, Mr. Munroe has done research work of high character.

SILVER continues to rise, standing now at 56 cents. This is greatly to the delight, as it is to the profit of the mine operators in the Cobalt, Tonopah, and other silver-producing districts. The immediate cause of the increase in price is said to be speculation in India and China. Back of that and as a solid basis for the speculation stand improved business conditions in the Far East and a wider local demand for silver in the arts. When one photographic supply company endeavors to contract for ten million ounces yearly, new point is given to the admonition 'Take a Kodak with you.'

QUEENSLAND'S gold production in 1909 amounted to £1,721,386, and the total recorded output has been £22,137,259, according to figures in the *Queensland Government Mining Journal.* New South Wales, among the States of the Commonwealth, has now the largest annual production, if all minerals be taken into account, it amounting to £7,403,210. Western Australia comes second with £7,226,544, and Queensland third with £3,656,564. New Zealand now adds £2,678,685 annually to the mineral wealth of the world. The total yearly output of the Commonwealth and New Zealand now reaches £27,286,464.

PYRITE contains, as is well known, two molecules of sulphur. It has also been known in a general way that one of these could be driven off at relatively low temperatures. Attempts to use this information commercially in the roasting of ores have not been successful and exact data regarding the composition of pyrite and the temperature at which it may be broken down are much needed. A start has been made at the University of California where an informal association of instructors and advanced students of chemistry is this year working on the sulphur problem under the inspiration of Mr. F. G. Cottrell. It has been determined that the first molecule of sulphur is driven off at 625 to 680° C. Within these limits the actual temperature seems dependent upon the length of the roasting. Mr. Arthur L. Day and his associates in the Geophysical Laboratory at Washington are understood to be engaged in an elaborate investigation of pyrite and the commonly associated sulphides. From these and other studies metallurgists may confidently expect data that will be of wide service when applied to practical problems.

GASOLINE motors are being introduced in the coal mines for gathering cars. Between small mines where mule haulage is still profitable and large ones where electricity is economical, there are many, as there is a stage in development of the large mines, where motors are economical. The delay in introducing them has been due to danger from their operation. Provision is now made against this by passing the exhaust through a tank containing lime water. One of the recent types of 4-cylinder water-cooled engines develops 50 horse-power and hauls coal at a cost of one and one-half cents per ton mile, allowing 5 per cent for interest and 10 for depreciation. While haulage problems in collieries are much more important than in metal mines there are places where such an engine is used to advantage in handling ore, the Yellow Aster mine of California being an instance.

JUMBO EXTENSION has been much in the public eye recently. The properties owned by this company at Goldfield, Nevada, are so intimately interrelated with those belonging to the Goldfield Consolidated Mines Company that under terms of an agreement made in settlement of conflicting apex and dip claims, they are worked by the larger company, the profits on the ore being paid to the Jumbo Extension Mining Company. There has been minor friction between the two companies, and Mr. C. A. Herzig, who recently examined the properties as consulting engineer for the Jumbo Extension, made recommendations looking toward certain changes and increased activity in working Jumbo Extension ground. Negotiations are also under way for use of a separate shaft and for the Nevada Goldfield mill to handle this ore. In due time doubtless this or other equally satisfactory arrangements will be effected. That the ground is rich is well known. Mr. Herzig's estimates of reserves have been widely published. There has been an attempt to discredit his estimates, and in our news columns October 22 a rumor to the effect that they were exaggerated was quoted. Such statements are common. The signed statement of an engineer should naturally be given greater weight than an unsigned rumor.

Geological Survey Men and Foreign Travel

Geological investigations within the Panama Canal Zone have heretofore been primarily directed to solution of immediate economic problems. Mr. Ernest Howe, among others, has made notable studies of this sort. A great public work, however, such as the Panama Canal, should be carried on as well as conceived, along the broadest possible lines. If there are data of value to science to be collected and recorded, full provision for this should be made as well as for 'making the dirt fly'. We are glad to be informed that officers of the U. S. Geological Survey are to make a complete examination of the Culebra cut. The investigation should be extended to cover the whole Canal Zone. It has been one of the curious anomalies of the public service that, whereas officers of other branches may travel in any part of the world where they

may be called by their work, a member of the Geological Survey can not go outside the United States except at his own expense. Work in Alaska is provided for by special appropriation but even when the Director officially represents this country abroad, as at meetings of the International Geological Congress, he must personally meet the bills. When it was desired to learn something about the actual working of the system of leasing mineral lands as practised in Australia, it was necessary to send a special agent there at private expense. The Geological Survey is practically the only branch of the public service against which this discrimination is practised. It is unjust to the men, operating either to limit their opportunities to get at the facts essential to their investigations, or to subject them to large personal expense in spite of their small salaries. There should be reason in all things and the demand for work at Panama may well be made the occasion for providing for a reasonable amount of foreign travel by the geologists where it is to the public interest.

The Creed of Conservationists

In the last few years no subject has been discussed in America more generally than the necessity and means of conserving our natural resources. There is a wide realization of the fact that the time has come when we must change our methods of exploitation and development, to the end that there be less waste of the heritage we have received, and a larger residuum to pass on to our successors. We are all conservationists, at least in principle; the sharp differences of opinion which have arisen are with reference to means to be adopted and the particular steps to be taken. Many men have many minds, and opinions result from inheritance, training, and environment as well as from sound argument. Equally earnest and honest men differ widely as to what changes in our system are necessary and what are wise. The first requisite to any concerted action is a correct understanding of the position of each party to the controversy. In parts of the West there has been much condemnation of the conservation movement. We believe it to have been founded largely on misunderstanding. Mr. Gifford Pinchot, who stands as the leading proponent of the movement, has recently issued a full statement of the plans and purposes of himself and his followers. There need be no doubt as to exactly what Mr. Pinchot proposes, and there can be no doubt that up to the present he is the most conspicuous and influential leader of the conservation forces.

In his recently issued book, 'The Fight for Conservation', Mr. Pinchot states the principles of his party substantially as follows:

"The first great fact about conservation is that it stands for development. There has been a fundamental misconception that conservation means nothing but the husbanding of resources for future generations. Conservation, however, demands the welfare of this generation first, and afterward the welfare of the generations to follow. There may be just as much waste in neglecting the development and use of certain natural resources as there is in their destruction. Conservation stands emphatically for the development and use of water-power now. It stands for immediate construction of navigable waterways. The development of our natural resources and the fullest use of them for the present generation is the first duty of this generation. In the second place, conservation stands for the prevention of waste. In the third place, the natural resources must be developed and preserved for the benefit of the many and not merely for the profit of a few. Conservation means the greatest good for the greatest number for the longest time. Conservation demands the application of common sense to the common problems for the common good."

Stated in this form, there will be but little disagreement with the principles Mr. Pinchot has enunciated. That development is of first importance is particularly the creed of the West, and certainly there can be no dispute as to use being the best possible means of conservation. There can be no gain in allowing water to run unused to the sea; and, while forests may be destroyed and coal burned, if farms and prosperous agricultural communities replace the one and manufactured articles result from the other, the best of conservation has been effected. All this, however, affords no excuse for continuing methods of use that involve unnecessary waste or, and here is the field for dispute, giving to the few the opportunity for development of the resources if it be to the unfair expense of the many. It is around Mr. Pinchot's third proposition that conflict mainly rages. There are those who argue that conservationists have nothing to do with questions of ownership, that the latter involve problems in political economy rather than in technology. There are also those who insist that the indirect benefits to a community following from development of a water-power, for example, are sufficient compensation to the community; that the direct benefits should go to those who give time or service to bring about the development. Others insist that some part at least of the direct benefit shall go to the people at large as well as to the promoters and immediate owners. Over all is the cloud of controversy that has obscured discussions of monopoly since development began. It is clear that problems of conservation and problems of ownership at times run counter, but it is equally evident that in the present state of public opinion the two must be considered together. The large corporations familiarly known as 'trusts' are so unpopular that any public enthusiasm for conservation, if it inure to their benefit, is unthinkable. This may be foolish and short sighted, or it may be wise and far sighted; in any event, it is one of the facts to be considered. Let us agree that there shall be development, let us work toward better technical performance to the end that waste be reduced, but let us also recognize that problems of ownership will inevitably enter into the matter, and as citizens let us keep open-minded and fair. There can be no satisfactory termination of the matter until it is settled right, and a right settlement must be one which is fair to both corporations and people.

Native Methods in Siberia

By Fred L. Lowell

During a recent trip to the placer mining regions of eastern Siberia, I had an exeellent opportunity of seeing the working methods used by the Russians, Chinese, and Koreans in the alluvial diggings of that country. Their ways, in many respects, resemble those used in California in early years. They were so interesting, and showed such ingenuity that they will bear deseribing, as will also some of the customs of the people.

The principal means of entry into this mining country is by way of Vladivostok and thence by the Trans-Siberian railway and river steamers. Before landing at Vladivostok, all passports had to be examined and 'visayed,' or countersigned, and the baggage examined. At every hotel the passport is taken from the traveler and sent to poliee headquarters for examination, and hotel keepers are subject to a fine if they neglect to perform this duty. I

Native Batea of Wood at the Left.

found it inconvenient to be awakened at 5 o'cloek in the morning to deliver my document and answer questions, but had to bow to the inevitable. From the moment that I landed, a military atmosphere appeared to surround me. The eity is bristling with fortifications and the population seems to be eomposed mainly of officers. No eameras are allowed to be used in the city and they are promptly confiscated if this command is disobeyed. Then again, the great Trans-Siberian railway is a strategic system, and the authorities object to snap-shots of the stations or guard-houses along the line, but by a little strategy of my own I managed to get a few. The railroad is of 5-ft. gauge and the rolling stoek for passenger service is modern and eomfortable, especially on the express trains. A train consists of five eoaehes, including a dining car in which good meals may be obtained at moderate priecs. These trains travel about 20 miles an hour and make many stops. The locomotives burn wood.

In passing through Manchuria, I saw much rich land suitable for growing grain and vegetables. I am told that the native Chinese are not permitted to bnild villages within a certain number of miles of the railway for strategie reasons. On crossing the border into Siberia all passports and baggage had to be examined again, after which we passed on northward to the head of navigation on one branch of the Amur river. The ferry boat erossing the river is anehored by several hundred yards of eable which is supported on floats, and the boat is forced aeross by the current of the stream. Some of the river steamers are side and others stern-wheelers like the ordinary Mississippi River boats. They burn wood, of which there is an abundant snpply, taken on at intervals along the river. I used a Siberian pony in

The Native Current Ferry.

traveling from the river to the mountains. This animal is small, standing about fourteen hands, but tough and hardy; well adapted to the work on the bad roads.

On arriving at the plaeer mines, I was surprised at the amount of mining that had been done and was still being done by the Russians, Chinese, and Koreans. In some places, all the gravel that would

Removing Water With Bucket and Sweep.

pay to work had been washed and great piles of tailing remained to be re-washed, possibly, at some future time by modern maehinery with low working costs. All the alluvial ground that I saw was 'Cabinet' or Government ground, and the Chinese lease it from the Government, the leases being either for one or two years. The gravel averages about 14 or 15 ft. in thickness and the payable portion next to the granite bedrock is 1 to 3 ft. thick. The rich portion is called 'plast.' After diverting the waters of the

stream, the unprofitable gravel is stripped off as fast as the ground thaws, which is at the rate of about 6 to 7 in. per day, unless it be covered with a clay overburden. This thaws 1 to 2 in. per day, and in one instance I saw the men using picks to dig up this frozen clay in order to get to the gravel quicker. Although they save time in this way, yet they waste much time in other ways, such as drinking tea and standing around smoking. The working season is about 160 days and only a day shift is employed. The custom is for a company of Chinese to take a lease on a section of a creek and work it in co-partnership. The men appoint one of their number as 'boss man' and obey his orders. The Government has an agent in the district who supervises the work. He locks the boxes in which the gravel is washed and is present when they are cleaned up at the end of each day. The Chinese remove the gravel from the riffles and pan it down in a wooden pan of their own pattern, after which the gold is separated from the black sand by blowing, and the inspector seals it up and puts the Government stamp on the package. He is responsible for the percentage claimed by the 'Cabinet.' He also keeps the records of the gold output of the district and superintends the putting down of prospect shafts in virgin ground. In some instances when the lease is a short one, the Chinese strip ground that would pay to wash, but often discard it in order to get down to the richer bedrock gravel more quickly.

The water from the thawing gravel is drained into a swamp from which it is raised by several devices. One consists of a bucket attached to one end of a weighted pole similar to the old-fashioned well-sweep. Another is by a bucket which is swung by a rope between two men, much the same as an ordinary swing, except that the bucket is lowered to the pool to be filled and raised on the forward swing and emptied about 10 ft. higher up into a flume. A third method is to use a wooden pump, as shown in one of the illustrations. The gravel is transported in barrows to the washer, which consists of a box about 8 ft. long with an iron screen on one end having ½-in. holes. The coarse is thrown to the waste pile and the fine gravel, dropping through, passes over the riffles, which sometimes have fine twigs packed between them for catching the gold. The cleaning-pan is made of wood with a smooth concave face. One of these bateas is shown in an accompanying illustration. In appearance it resembles the cross-section of a jar.

On one of the rivers, I witnessed the operation of some native dredges. These consist of two rafts made of logs. One raft has a well in the centre for the scoop, which is made of iron and is fastened to the end of a long pole. The rafts are held in place against a three-mile current by four spuds, one at each corner, and sometimes by a guy-rope to the bank. Before lowering the scoop, the bottom of the river is loosened by dragging the end of an iron-shod pole through it, and then the scoop is dragged from the farther end of the raft to the windlass, after which it is lifted up to the platform. The gravel is then shoveled into the hopper of the washer and the oversize thrown into the river. The box is the same as those used on shore except that it is set higher

Unloading River Steamers.

Washing Gravel in the Puddling Box.

Gold Dredgers at Work.

Dredging a Sand Bar.

and the water for washing is pumped from the river. These dredges do not work to bedrock, but handle gravel containing gold from surface concentration and are more effective in shallow water. The 'Cabinet' officer superintends the clean-up and puts his official seal on the package containing the gold. The Koreans who operate these dredges make enough money during the summer season to keep them through the winter in Korea, returning to the diggings for the next season's work.

These operations are some of the many that are going on in the headwaters of the Amur river and the production in some of the districts has amounted to many thousands of rubles, as shown by the 'Cabinet' records. There are many instances where illegitimate mining is carried on by Chinese who are taking out gold from placers unknown to the officials, and who do not return royalty to the Government. These men are constantly appearing at supply points for their provisions and disappear mysteriously during the night to pursue their labors. Like other mining countries, this one has its dangers. Many crosses by the roadside bear witness to the murder of some unfortunate Chinese or Korean who has been shot from ambush as he was traveling to the river to embark for home. These bandits do not give the victim a chance for his life; not living content with robbery alone, they kill as well. The police write a description of the deed or what is called a 'protocol,' which goes to headquarters and is forgotten. Foreigners are not molested as much, for in such case, more energy is exerted by the police to capture the murderers and the chances of a residence in a penal settlement are greater. Speaking in a general way, the country is a good one for mining. Placer gold is scattered over a wide area, very rich in some districts and just profitable in others. Many of the difficulties encountered in Alaska must be overcome also in Siberia.

SHRINKAGE OF EARTHWORK

How much earthwork shrinks and the comparison of excavation and embankment quantities are very important subjects upon which the opinions of engineers are much at variance. They are also much mooted subjects between engineers and contractors. Shrinkage is provided for in several ways: (1) By raising the height of crown above the established subgrade by a percentage of embankment height. (2) By adding additional width to the standard crown width. (3) By combining methods one and two. (4) By adding a shrinkage percentage to the height of embankment, computing a new slope distance for this corrected height, thus increasing the width between slope stakes.

The Colorado bumping table is a suspended plane, hanging by rods. A cam pushes the table out of its natural position, and the table swings back toward its original position, striking sharply against a stationary object, which gives the table a 'bump,' hence its name. For some purposes it is a very satisfactory concentrating device, but not extensively used away from its home in Gilpin county, Colorado.

Lead and Copper Slags

By James A. Barr

*In lead smelting the operator is confined in the beginning in the selection of charges by the comparatively rigid limits of the regular type slags, a number of which are given in the following tables. By this statement is not meant that the so-called 'type slags' are the only ones that will work properly but rather that certain slags which have been tried are known to be satisfactory. The metallurgist may often have to sacrifice what he considers good metallurgical practice to obtain the greatest net profit, hence the type slags are not always followed. In the following table the analyses of type slags are given with the remarks on each. Under the columns headed MnO, MgO, BaO, etc., are given the maximum percentages of these substances that have been used with the corresponding type. By this it is not intended to imply that the entire list of impurities would be allowable in one slag to the extent of the maximum figures given. For the maximum percentages of one impurity in the presence of others, the reader is referred to the explanations following the table. A slag is designated as whole, half, quarter, etc., according to the ratio of the FeO + MnO to the CaO + MgO + BaO. Thus in a half-slag the CaO, etc., is approximately one-half the percentage of FeO. When the MgO, etc., is added to the CaO it is added according to its replacement value; thus 40.3 lb. of MgO is equivalent in fluxing power to 56.1 lb. of CaO. By the word 'charge' as in 'per cent lead on the charge,' is intended the blast-furnace charge including ore and fluxes but not the coke or slag for re-smelting. In the 'Table of Limits' is given the maximum, minimum, and average figures for slag constituents found in practice, also figures for other data important to silver-lead smelting. Unusual figures are enclosed in brackets.

SLAG TYPES

		Per Cent.			Limits with Corresponding Type Slag. Per Cent.				
		SiO_2	FeO + MnO	CaO + MgO + BaO	MnO	MgO	BaO	ZnO	Al_2O_3
A	1	35	28	28	5	5	2-5	10	6-10
	1	36	31	23	5	5	2-5	10	6-10
B	2	34	34	24	5	5	2-5	10	6
	1	35	38	17	5	5	2-5	8-15	6
C	2	31	38	21	5	5	2-5	8	6
D	1	30	40	20	8	5	5	8	5
	1	32	47	11	8	5	5	8	5
E	2	30	48	12	8	5	5	8	5
	1	28	50	12	8	5	5	8	5
F	2	28-30	54	6	8	5	5	8	5

REMARKS

A—Useful in case of an excess of silicious ore and for ores containing much alumina. It is not adapted to ores high in zinc.

B—More fusible and faster running than A, but still too silicious for ores high in zinc.

C—This type may be used successfully to work off zincy ores.

D—An excellent slag adapted to working irony ores; also good for zincy slags.

E—A good slag for working off irony ores, where they are in excess or most profitable to treat.

F—Not as good as the preceding types and of rather high specific gravity. Only used in case of an excess of irony ores and where silicious fluxes are not available at a reasonable cost.

*Abstract from 'Smelting Properties of Copper, Lead, Gold, and Silver Ores,' in 'Testing for Metallurgical Processes.'

EFFECT OF SLAG CONSTITUENTS

Alumina.—Aluminous slags will generally be slow running. They require a higher heat to make them flow properly than their temperatures of formation would indicate. Iles recommends that the iron content be kept well advanced and the silica be between 29 and 31 per cent.

Baryta.—This enters both the slag and matte and increases the specific gravity of slag so as to make proper settlement of matte difficult, otherwise it is a good alkaline earth flux. Baryta ores have been successfully handled by using a slag running SiO_2, 35 to 37%; Fe, etc., 20; lime, 27; BaO, 14.

Lime.—In general high lime makes slags low in lead except where zinc conflicts and requires the iron to be increased.

Magnesia.—Magnesia is especially troublesome in the presence of zinc and alumina, forming streaky, pasty slags high in lead. In a slag containing 8% zinc and 2 to 3% baryta, MgO is troublesome and 5% will give serious trouble. Magnesia alone and under 5 to 8% will give little trouble when intelligently handled. It has 1.4 times the replacement power of lime.

Potash and Soda.—These elements in excess will cause slags to run high in lead but good results may be obtained by using a hot slag containing 17 to 22% of alkaline earths.

Zinc.—Zinc decreases the fluidity of the slag and, while it lowers the temperature of formation, more fuel is required to make the slag flow properly and keep the lead content down. Zinc enters the matte and decreases the specific gravity making it difficult to settle properly. An excess of zinc is best taken care of by irony slags as indicated in the table. It is customary to preserve the slag type by replacing lime with one-half the zinc oxide present, and adjusting all the constituents so as to add up to the percentage of the original total. The amount of zinc volatilized depends upon how well the ore has been roasted and the zinc changed into oxides; a poorly roasted ore will result in a low volatilization of zinc. The amount of zinc volatilized and going into the matte will run from 10 to 20%. Following is example of slags, etc., resulting from smelting zinc retort residues:

Base bullion.	Slag.		Matte.	
		Per cent.		
Ag .....87.5 oz.			Ag .....19.0 oz.	
Au ..... 1.49 oz.	SiO_2	.....31.1	Au	0.04 oz.

Sulphur on charge.....	3.7	Lead	92.0
Matte formed	7.2		

GENERAL REMARKS

The slags to be re-smelted, consisting regularly of the shells from the slag dump-pots and any foul slag from clean-ups or unfavorable runs, will average about 20 to 30% of the total 'charge,' and even 35 to 40%; the term 'charge' referring to ore fluxes, but not the coke or slag for re-smelting.

Iron.—Where iron fluxes are dear a good slag would be: SiO_2, 32%; Fe, 32; CaO, 22; Zn + Al_2O_3, 10.

Base Bullion.—There should be enough precious metal on the charge so that the silver content of the base bullion will run between 100 and 300 oz. per ton and at least 0.10 oz. of gold per ton, as the refiners pay only for 0.50 oz. or over. The richer the bullion the greater the amount of precious metal that will be found in the slag and matte. A typical base bullion contained, Ag 266 oz., Au 3.49 oz., Pb 95.0%, As 0.28, Cu 0.70.

Lead.—For efficient collecting of the values, the percentage of lead on the charge should not be under 6 and is better 10. Over 20% is liable to force too much lead into the slag, though in one smelting works as high as 30 to 35% lead has been placed on the charges and the resulting slags have contained less than 1% lead under favorable conditions.

Fuel.—The quantity of fuel is lowered by high sulphur and a high percentage of lead on the charge, also by an easy running slag having a low temperature of formation. The maximum fuel under these conditions has been as low as 9 to 10% of coke.

Matte Fall.—The quantity of matte formed will depend upon the amount of sulphur available after volatilization and slagging. The slag will contain about 1% sulphur and the volatilization will be from 20 to 30% depending upon the condition of the ore; an unroasted ore will give a higher loss of sulphur than a roasted product. The matte fall should average about 10% in order to keep down the silver-lead content of the slag, and allow the handling of more impure and refractory ores than the lower matte falls given in the table. Low matte fall may be used with pure siliceous ores in the absence of $BaSO_4$. It will also depend upon the cost of roasting and re-smelting the matte. Where manganese is substituted for iron in the charge it lessens the production of matte.

Matte Content.—The matte should ordinarily con-

tain not less than 5 and not more than 14% copper to cleanse effectually the slag of silver. When in excess of 14 some of the copper is reduced and goes into the base bullion where it must be removed by drossing and returned to the blast-furnace. Since the matte is roasted and returned to the furnace, the copper accumulates and when in excess of the limit desired, it is removed and smelted separately to form a converting grade of copper matte. The lead, which is mostly volatilized in this process, is collected in the bag house. The following charge may be used for the concentration: (1) matte roasted to 4% sulphur; (2) silicious ores as free from S, Au, and Ag as possible; (3) copper ores; (4) limestone; (5) slag; (6) coke, 13 to 14%. The slag should run between 35 and 42% SiO_2. The matte formed should contain about 50% Cu and 15 to 20% Pb. Scrap iron may be added to the charge to the extent of 5 to 10% to lower the lead content of the matte, which should ordinarily run between 12 and 14% but can be reduced to 7 or 8% should the conditions warrant. It is not advisable to use scrap iron when there is much zincblende present, because metallic zinc is reduced and oxidizes to ZnO in the upper part of the furnace, forming accretions and preventing free combustion of the coke from the coating of oxide upon it. A lack of fuel to sufficiently superheat the slag and give proper reducing conditions is quite apt to produce a matte high in lead. In general a slag of 25 to 28% FeO is best suited for producing a matte low in lead. The lead also increases with the copper in the matte, namely, a 40% copper content may call for 20% lead. A typical matte analysis is: S, 20.29%; Fe, 35.0; BaO, 0.73; Zn, 6.42; Pb, 10.96; Cu, 14.8; Ag, 77 oz. per ton; Au, 0.18 oz. per ton; specific gravity, 4.64.

Speiss.—When sufficient arsenic is present to form a speiss, 2.3 times the weight of arsenic equals the weight of iron needed to form it. This must be subtracted from the total iron in the charge as it is not available for slag or matte. The per cent of speiss formed may be approximated by running a regular lead assay on the ore and noting the weight of the speiss button found with the lead. Ores forming much speiss should be run with a silicious slag in order that the temperature of the furnace may be high enough to keep the speiss liquid.

Losses.—In best practice 90 to 95% recovery of the lead and 98% of the gold and silver can be obtained.

Flue Dust.—The amount of flue dust will run from 0.3 to 3.5% (and more) of the total charge according to the amount of fine material and the strength of the blast. An average figure would be 2½ per cent.

Lead Roasting.—The question when to roast will be decided by the matte fall desired. Sulphur is commonly debited at 25c. per unit, which represents the approximate cost of handling and reworking the resulting matte. Then, since for each unit of sulphur driven off in a roast, 25c. is saved, the advisability of roasting may be estimated by taking into account the cost of roasting and the resulting losses which are from 2 to 7% of the lead and 1 to 5% silver, but can be kept within 3 to 4% lead and 1 to 2% silver with a trace of gold. The change in weight of a roast approximates the replacement of sulphur by oxygen and also in the case of a pot roast the loss of CO_2 of the limestone when used.

The copper slags are usually classed according to the ratio of the oxygen on the base side to the oxygen on the acid side. Iron and lime oxides being the chief bases and silica the principal acid.

(1)	Subsilicate ..... Ratio 3 to 2.	$3ROSiO_2$
(2)	Singulosilicate ..... Ratio 2 to 2.	$2ROSiO_2$
(3)	Sesquisilicate ..... Ratio 2 to 3.	$4RO3SiO_2$
(4)	Bisilicate ..... Ratio 1 to 2.	$ROSiO_2$
(5)	Trisilicate ..... Ratio 1 to 3.	$2RO3SiO_2$

In these equations RO represents the oxide of any base or combination of bases.

The silicate degree of a complex slag is found by taking the percentage of oxygen in the SiO_2 or acid side and that on the base side by the use of the following table and determining the ratio.

	Per cent oxygen.
Silica, SiO_2	53.35
Iron oxide, FeO	22.2
Manganese oxide, MnO	22.6
Lime, CaO	28.6
Magnesia, MgO	40.0
Baryta, BaO	10.5
Alumina, Al_2O_3	47.0

For example, take slag of the following analysis:

	Per cent.	Per cent O on base side.	Per cent O on acid side.
SiO_2	40.0	...	21.3
FeO	30.0	6.7	...
MnO	5.0	1.1	...
CaO	20.0	5.7	...
MgO	5.0	2.0	...
		15.5 = x	21.3 = y

x:y as 15.5:21.3 = 1:1.37; approximately 3:4 or $3RO,2SiO_2$.

The **subsilicate** would only be used in case of a great excess of basic ores, usually irony, with silicious fluxes not available at a reasonable cost. Slag of this type requires a high temperature to run properly; they are corrosive to crucible linings, and are of too high specific gravity to make a clean slag, and hence are generally unsuited to economical smelting except in extreme cases. The **singulo silicate** enters the range of ordinary commercial slags and is used where iron or other bases are in excess. It is still of too high specific gravity to give a perfect settlement of the matte and is seldom made where silicious ores are obtainable at a fair price. The **sesqui silicate** is a mixture of the singulo silicate with a bisilicate, and in the neighborhood of this silicate degree the majority of the copper slags may be placed. It has a low melting temperature and runs smoothly without forming a thick crust over its surface. It is low enough in specific gravity to permit a complete and rapid settling of the matte. It is perhaps the most desirable slag when conditions permit its use. The **bisilicates** are used in case of an excess of silicious ores. While they require a higher

percentage of coke on the charge than the preceding slags, still when they are properly melted, give a slag of low specific gravity and a very clean separation of the matte. A **trisilicate** comes more within the range of the iron blast-furnace. The following table gives the limits of the different slag constituents as found in modern practice.

supplemented by the remarks on alumina which are given following the table. The table may be used in a like manner to find the average figures for other slag constituents for all common types of smelting, also other data, such as matte fall and fuel on charge. The column heading 'Min.', is intended as an abbreviation for minimum. These columns contain the

*By the concentration ratio is meant the ratio of the per cent copper on the 'charge' to the per cent in the matte.

By 'ordinary matte smelting' is meant that practice which uses raw or roasted ore with low concentration, of say 4 or 5 into 1, and 10 to 15% of fuel, and primarily for the reduction of copper ores with gold and silver as by-products. By 'semi-pyrite' smelting is meant that type which uses a high concentration ratio, silicious slags, as small amount of copper on the charge as possible, pyrite being used as a flux and fuel if available, but primarily smelting is for the collection of gold and silver from unroasted ores that are not suitable for amalgamation or leaching methods. By 'pyrite smelting' is meant a smelting of raw heavy sulphide ores for the collection of their copper content, also gold and silver, with the least possible addition of lime and silicious flux. It is not possible to define sharply all types of smelting by these three divisions as there will be gradations of one into the other as conditions require. Ores for regular pyrite smelting should contain 60% of pyrite or its equivalent.

Example.—The use of the table may be illustrated as follows. In deciding on a slag for smelting a copper ore by ordinary matte smelting it is desirable to see how high an alumina content may be used. Opposite Al_2O_3 in the column headed 'Constituents of Slags' and in the column headed 'Ordinary Matte Smelting.' 'Average per cent Max.' is found the figure 10, which indicates that under average conditions 10% Al_2O_3 may be used in a slag. In a like manner under the column headed 'Special per cent Max.', is 15, which indicates that in special cases 15% Al_2O_3 may be used in a slag. These figures are minimum or lowest figures found in average as well as special cases.

NEW TOPOGRAPHIC MAPS

The topographic maps named below have been recently issued by the United States Geological Survey:

Bedford, Pa.
*Bisbee, Ariz.
Bouldin, Cal.
Breckenridge special, Colo.
Carson Sink, Nev.
Castle, Cal.
Clay, W. Va.
Danforth Hills, Colo.

*New editions.

The United States relief map sells for 10c.; the administrative map of Yosemite National Park sells for 25c.; the other maps sell for 5c. each. A discount of 40% is allowed on purchases of topographic maps amounting to $5 or more at the retail rate. Payment should be made by certified check or by postal or express money order, payable to the Director.

National, Nevada

By H. C. Cutler

National, the latest camp to attain prominence in Nevada, is in the northern part of Humboldt county. It is about 8 miles south of old Fort McDermitt and the Oregon line, and 75 miles north of Winnemucca, on the Southern Pacific and Western Pacific railroads. It lies well up in the mountains bordering the eastern edge of Quinn River valley and, unlike the majority of camps in Nevada, is rather pleasantly situated. Water and grass are plentiful and sagebrush and green shrubbery cover the mountain sides. Cottonwood and other trees are found in the gulches near the water, but not in sufficient quantities to furnish fuel for any length of time.

At present, the population of the town and vicinity is about 750. A daily stage brings the mail from Winnemucca over a road which is excellent for the larger part of the year. Freight and express are delivered in town for 1½c. per lb. A few wooden buildings have been erected, but the town is still largely composed of tents. The camp was established in June, 1907, by Jesse L. Workman, a prospector who used an automobile for transportation and who during the past six years had been over a large part of Nevada. He was attracted to this section by stories of high-grade float found at different times by sheep-herders or cattlemen who had neither the time nor the inclination, nor yet the knowledge, to follow up and discover the source from which it came. Workman located forty claims in the vicinity, but was not fortunate enough to find the high-grade deposit. Credit for this belongs to lessees who were attracted to the camp by the reports sent out by Workman. Among these were George and Frank Stall, who had mined in California and prospected in Nevada. They took a lease on the West Virginia claim on Charleston hill and, although often discouraged, out of money, and ready to give up, stuck to it and finally found the bonanza deposit in February 1909. Meantime, four of the claims located on Charleston hill had been incorporated under title of the National Mining Company, and control of the company secured by S. W. Gundaker, who kept the lessees hopeful and working until they were rewarded by finding the highest grade ore ever found in place. Later, a change in ownership of the control caused a dispute as to the rights of the lease, and litigation ensued which tied up the property during a part of 1909 and 1910. The suits were finally compromised and on April 9, 1910, work on the lease was resumed with a year and twenty days to run. In August 1910 the lease was sold back to the parent company for a large sum, although it is generally supposed that the best of the rich ore-shoot had been extracted. From April until August 1, 1910, the production of high-grade ore alone exceeded $650,000. This ore was worked in a small pan-arrastre mill and the tailing shipped to the smelter. The ore averaged $25 per pound, assaying in the ratio of about an ounce of gold to an ounce of silver.

General View of National, Nevada.

The geology of the country, both in the mine and its vicinity, is complicated. The camp lies near the southern edge of the Idaho lava flow. To the north and east, the mountains are capped with heavy flows of basalt and the gold-bearing Tertiary eruptives do not come to the surface. Beginning at Eight-Mile creek, about two miles north of National, the rhyolite and andesite appear and can be traced for a number of miles to the south. Buckskin peak, about three miles south of camp, is nearly all rhyolite. Farther south, the more ancient rocks, such as limestone, schist, slate, and granite, appear. All of this range is being closely prospected at the present time, but so far nothing of commercial value has been found outside of Charleston hill, where the Stall lease was situated. Scarcely enough work has been done in the mine to determine the actual geological conditions with certainty. A north-south break traverses the property its entire length and has been traced for several miles in the adjacent claims. This break has every indication of being a faulting plane —heavy gouge, crushed quartz, and country rock, smooth boulders embedded in the clay, and striations on the wall. All of the Stall lease workings are in this fault plane, and all of the high-grade ore extracted up to the present time, with the exceptions noted later, has been in the form of smooth boulders and pebbles or in crushed quartz. The rocks vary in size, from a pin-head to pieces weighing 150 lb. When small they are scattered throughout the gouge and crushed quartz near the wall or fault plane and make from a foot to 18 inches of mill ore assaying from ten dollars to several thousand per ton. This mill ore is, however, confined strictly to the high-grade shoot, and is necessarily limited in amount. The fault plane, starting with a dip of 49° at the surface, gradually straightens until at the 400-ft. level the dip is 80°. The east side of this break is a highly silicified rhyolite and the west side, where the ore occurs, is andesite. There is every indication that the west side has been raised, but just how far it is impossible at present to tell on account of the limited amount of development. The andesite belt is apparently not over 300 ft. wide, and directly west of it is a diorite dike, not more than 100 ft. thick. Farther west, the rhyolite appears again lying over the diorite. Basalt dikes cut through both the andesite and the rhyolite, with a general north-south trend, but I do not believe they have any relation to the ore

deposition. It was originally believed that this main break was a contact fissure in which the ore was formed and afterward broken and displaced by a general faulting movement, and still later slighly re-cemented in places by a later solution. Development has tended to disprove this theory and the present indications are that the ore was derived from a vein in the andesite striking S. 20° E. This vein is one of a series of parallel veins cut and displaced by the fault. All of these veins do not carry ore of commercial value, although it is possible that high-grade ore will be found in some of the others. If this contention of a general faulting plane is true, and now it appears to be the only reasonable explanation, then all the ore mined up to the present time is simple 'drag' from this main vein and the fault has broken through and displaced the ore from a phenomenally rich ore-shoot. No ore has been cut by the fault, although a drift was run several hundred feet south. It is quite possible that there are parallel veins carrying ore of value farther south, and a number of lessees are working in that vicinity with this idea in mind.

Some work was done on this main vein, and a few pounds of ore of the same phenomenal richness taken out, but on account of the limited hoisting facilities and the appearance of so much high-grade ore in the faulting plane lower down, work was discontinued later. Several thousand feet of work has been done by the National Mining Co. on this fault plane north of the Stall lease, but up to the present time no ore of any kind has been found beyond a point 50 ft. north of the lease boundary. Quite recently on the Hyde lease, in a block of ground about 1500 ft. north of the Stall lease some of the high-grade was found in one of the parallel veins in the andesite. This may lead to another bonanza deposit. At the Stall lease, while operating, 75 men were employed. It was equipped with a 25-hp. Fairbanks gasoline hoist, a 1600-lb. skip, a No. 4 Buffalo exhaust fan, and a complete high-grade plant. A change-room, with lockers and wash-rooms, was provided for the miners, and a complete change of outside garments required.

The high-grade ore, assaying over $20 per lb., was taken out in sacks to the mill, crushed in a small Blake crusher to ½-in. mesh, then re-crushed in a small laboratory crusher to ¼-in. mesh. From this crusher it passed to a No. 2 cone-grinder and finally to a Braun disc-grinder, where it was pulverized to pass a 60-mesh screen. The pulp was then put into a 4-ft. pan-arrastre with the proper amount of quicksilver and water and amalgamated for six hours. About 150 lb. of ore was run to a charge and four charges in 24 hours. An extraction of 98 to 99.5% was made by the process and the tailing shipped to the smelter. About $650,000 in bullion was turned out of this little mill in less than three months. Besides the high-grade ore, three other grades were made: seconds, assaying from $2 to $6 per lb., high-grade mill ore, $100 to $1000 per ton, and low-grade mill ore, anything assaying over $8 per ton and too low grade for other classes. The last three grades were placed in bins or on dumps until such time as other means of reduction could be obtained.

At the present time, the centre of activity in the district is on Charleston hill, and a number of lessees are working on the National Mining Co.'s property and on adjacent claims both north and south. Among the more prominent properties being developed in this way are the National Consolidated, the First National, the Charleston Hill Mining Co., and the Mayflower. A mile from Charleston hill, in the suburbs of town, the Radiator group is being developed under bond by Seattle capitalists. All of these different places will be watched with interest, as a discovery in a new place will mean much to the camp and possibly may cause another of Nevada's booms.

Stall Lease, National, Nevada.

Much of the knowledge regarding the flow of water in pipes to which engineers are today indebted is the result of extensive and expensive experiments made in Europe. Darcy, the noted French engineer, about 60 years ago, after studying the flow of water in pipes under pressure, extended his observations to the flow of water in open conduits, and to this end had built a channel nearly 2000 ft. long, and 80 in. wide. This channel was lined successively with various materials possessing differing degrees of roughness: the cross-section was given different forms, and the bottom varying degrees of slope, with a view to ascertaining the results of these changes on the flow of water through the channel. From the observations made at that time Darcy wrote his formula. This work was taken up by Bazin after the death of Darcy, and the experiments were continued on the same elaborate scale. In California, Hamilton Smith carefully gauged the discharge of water from riveted pipes of various sizes under varying heads, and the results of this line of investigation is considered as of equal importance with the Darcy and Bazin investigations and as reliable.

A Japanese Mining Exhibit

By Reiji Kanda

At the Japan-British Exhibition held at Sheperd Bush, London, this fall, the displays made by the mining and metallurgical companies of Japan were particularly good. Collectively they afforded an excellent picture of the present development of the mining industry in the Island Empire. Among the more important exhibits the following may be described.

In the exhibit of Chobei Tanaka, the predominating feature was the excellent display of cast-iron pipe, mild steel rods, bars, angles, pig iron, iron ores, and manganese ore. The exhibit represents the outcome of twenty-five years' hard work on the part of Mr. Tanaka and his assistants, and the difficulties to be overcome were almost insurmountable. The firm has a large business in the shipment of pig iron, cast steel, and cast-iron pipe. It owns the Kamaishi Iron & Steel Works on the Kamaishi harbor in the Province of Rikuchu, and branch works at Kurihashi, about sixteen miles from Kamaishi. It also owns and works several mines in the district and has a fleet of five steamers. The operations of the firm now cover also the smelting and export of copper, although it is only recently that this branch of the business has begun to pay. The annual value of the products of the company is about $855,000.

Mitsui & Co., Ltd., a firm of world-wide reputation, had the largest and most representative exhibit in the whole section. In addition to fine samples of refined bismuth, pig lead, coal, coke, and sulphur, there was a panoramic model of the new Miike harbor and large scale working models of Miike patent skip-loaders. These loaders, which were constructed by Head, Wrightson & Co., to the designs of the engineering staff of Mitsui & Co., are unique, and are capable of loading steamers at the rate of 500 tons per hour on each loader. Two are now at work and another is in course of construction. The loading of the skip and its discharge into the vessel take but a few minutes, and the result is that the cars are practically always on the move. As there is always a good depth of water in the harbor and entrance, Mitsui & Co. anticipate making this place a large commercial port as well as a coaling base. Some wonderfully good photographic views of the harbor and coal mines were shown. The amount of coal annually turned out by this company is valued at $5,710,000.

The great firm of Mitsu Bishi, which is about the largest and richest concern in the Japanese Empire, had a fine exhibit which included gold, silver, copper, coal, and other minerals. The samples of electro-refined gold and silver were especially worthy of notice, and the various grades of copper, both in the raw and manufactured stages, were excellent. Mitsu Bishi also sent over a sectional model of the famous Takashima coal mine, which showed the geological formations and the various levels under the sea. The coal from this mine is of good quality and is mostly supplied to the Japanese Navy. There were also views of various mines and refineries. The value of the products of both the coal and metal mines of Mitsu Bishi is $5,274,000 annually. The Furukawa Mining Co. had a good display of raw and manufactured copper and of various by-products therefrom. It also showed a relief model of the famous Kune copper mine. The annual value of this company's output is estimated to be about $4,370,000 and this concern, with the Mitsu Bishi Co., may be considered the pioneers of Japanese mining.

K. Sumitomo represents a family that has successfully worked the famous Besshi copper mine for over 200 years, and as the resources of this mine are apparently inexhaustible, a prosperous future is anticipated. Mr. Sumitomo had on exhibition a beautiful model of the Shisakajima smelting works. This plant is one of the most modern in the Japanese Empire. In addition to mining and smelting copper ore and the manufacture of copper and brass tubes, rods, sheets, and cables, Mr. Sumitomo does a large business in steel making and casting, and exhibited fine specimens of work of this class. Mr. Sumitomo's annual production of copper is valued at $1,840,000.

A glimpse at the exhibit of the Nippon Oil Co., Ltd., would have convinced the visitor that the various classes of illuminating and lubricating oils made are of high quality. The crude oil shown was from several different leases in the Echigo district and the specific gravity varied from 0.7919 to 0.9253. The gasoline refined from these samples is of specially good quality, both for engine and stove purposes, and the various lubricating oils shown compete with any in the world. The paid-up capital of the company is now $5,000,000; it gives employment to about 3300 people, and the area developed is about 6500 acres. When it is stated that the average dividend amounts to 25% per annum, it will be understood what a flourishing concern this is. The Nugata Iron Works Co., which is operated by the directors of the Nippon Oil Co., Ltd., showed heavy well-boring appliances, including their patent 'Shokudai' (or candle-stick) pipe-recovering implement. This receives its name from its resemblance to a *shokudai* or Japanese candle-stick. It is used for recovering casing and is successfully and easily operated.

F. Kuhara had a representative exhibit of the various ores and copper products from his Hitachi mine. This mine, which is situated in the Province of Hitachi, has been known for 200 years and is now classed as one of the four great copper mines in the Japanese Empire. It was originally opened by members of the Satake clan, but has, since its inception, had several owners. It came under the present management in 1905, and since then enormous progress has been made. The method of prospecting and exploration is by boring with Calyx drills. Large and small cores were shown. There is still a great area to be exploited, and it is anticipated that the present annual output, which is valued at $555,000, will be greatly increased in the near future by further exploration. The Fujita company, of which the head office is situated in the city of Osaka, has a large business which covers mining, agriculture, and forestry. It is one of the largest private concerns in

Japan and was started in 1864 by Denzaburo Fujita, who is still its president and is assisted by his son, Heitaro Fujita, as vice-president. The Kosaka mine, of which a large model was exhibited, is operated by this company. This mine was discovered in 1861 and until 1897 was worked for silver. A new process was then found which made it possible to extract copper from the complex sulphide ore, which hitherto, owing to its low grade, could not be worked profitably. The Fujita company commenced to work this metal principally, with the result that an abundant supply has been obtained since, together with gold and silver of no less value, though the latter exists in a very small percentage in the ore. Lead also is recovered. Some years ago metallic zinc was produced experimentally at the Kosaka mine to determine which could be produced more economically, copper or zinc. The verdict was in favor of copper and for the time being zinc is not being taken from the Kosaka mine, although experiments are now in progress with a view to extracting the zinc from the copper slag. The Fujita company also owns and works the Zuiho and Omori gold mines. The samples of gold and silver ingots, electrolytic copper, pig lead, and various ores obtained from all the mines were striking. There was also a chart showing the processes and products of the Kosaka mine from the time the ore is mined until the metal reaches the market. The annual output of the Fujita company is valued at $3,170,000.

The Hokkaido Colliery & Steamship Co., Ltd. (Hokkaido Tanko Kisen Kabushiki Kwaisha) is a large company in the northern coal district. This company is concerned (in conjunction with Armstrong, Whitworth & Co., and Vickers, Son & Maxim) in the construction of war supplies and the manufacture of steel. It has blast-furnaces and other plant at Mororan. Mororan, Otaru, and Hakodate are the open ports on the island of Hokkaido, and this company has coal sheds and loading plants at each. It does a large business in bunker coal and this trade is rapidly increasing. The value of the coal produced last year amounted to $3,165,000. A large lumber and general timber business is carried on profitably as side business. The Imperial Steel Works of Japan showed a large case of polished sections of mild steel joists, girders, bars, and some turned steel locomotive tires of three different diameters. They also showed furnace brick made from chamotte, silica, chromite (for Martin's furnace), and fire brick from agalmatolite. This is the only exhibit in this section which showed materials of this class. The firm also had on view manganese ore, magnetite, magnetite changed to hematite, dolomite, and limonite. The works have by-product coke ovens and recover coal tar, oil, pitch, and ammonia. The Association of Colliery Owners in the Province of Chikuzen and Buzen represents practically the whole of the mine owners in these two provinces, and their output of coal is more than 60% of the entire production of the Japanese Empire. Under the management of the Association the progress made in late years has been rapid. The exhibit comprised fine specimens of coal from the various mines. The coal is hard and is largely used for naval and railway purposes. There was also shown natural coke which has been formed by the intrusion of volcanic rock. This natural coke, or *senseki* as it is locally called, is found only in a few places in Japan, but is valuable owing to its high calorific power.

The Imperial Geological Survey Department had a large and representative exhibit comprising about 350 specimens. These included, among the minerals, samples of native elements, sulphides, silicates, tellurides, sulpho-salts, haloids, oxides, carbonates, neobates, tantalates, phosphates, sulphates, tungstates, and hydro-carbon compounds. There was a specimen of every kind of rock found in Japan. A large and varied assortment of fossils was shown, some being both wonderful and rare. The crystals of various kinds on view were especially fine, and many of them appeared to be new. There were also two large maps of the Japanese Empire (with the Korean peninsula), one showing the geological formations and the other the important mines. The maps were each 21 ft. square and every detail was easily and clearly understood. The Bureau of Mines sent over some models that represented the output and value of the various minerals at different periods. The descriptions indicated how marvelous has been the growth of the industry since 1880. The articles represented were coal (illustrated by miners of different heights), gold, silver, copper, and iron (by different sized ingots), and oils (by storage tanks). There were large charts showing the annual imports and exports of various minerals, the licenses granted for their production, and deaths and accidents in the mines.

The Yamato Metal Co., of Tokio, had an exhibit of their antifriction metal. This metal is in great demand throughout Japan. It is made of various mixtures of selected brands and in seven different degrees of hardness to meet all requirements. The Higher Technological schools of Tokio and Osaka have experimented with this metal extensively and some splendid results have been obtained. It has also taken medals and prizes in the various exhibitions and shows in Japan. The Yoshinotani Coal Mining Co., Ltd., (whose European agent is S. Samuel & Co., Ltd., of London) exports a large amount of coal for commercial purposes to Chinese ports and supplies about 30,000 tons of bunker coal annually to ocean-going vessels in Far Eastern waters. This company also owns and works the Yusenji copper mine. Considering that this mine was not opened until 1902 the production last year of about 700 tons of copper ingots is a very good result. The exhibit by the Yoshinotani company comprises coal (in block form), chalcopyrite, and copper ingots. The Kaijima Mining Co. and Yasukawa & Matsumoto are the largest independent colliery owners outside the Association in the provinces of Chikuzen and Buzen. Each of these companies has a number of well equipped mines with total outputs amounting to $2,635,000 and $1,285,000 respectively. These companies exhibited a number of samples of coal from seams of varying thicknesses together with very good specimens of oven coke.

Mining in the San Juan—I

By William H. Storms

On August 23 I left San Francisco on the Western Pacific railroad, by way of Salt Lake, for a visit to some of the mining districts of Colorado. I took the second regular passenger train leaving Oakland on the new road, returning by the same route October 20. The Western Pacific passes through an interesting country, including the picturesque canyon of the Feather river, in California; Lake Lahontan, a large ancient Tertiary dry lake in Nevada and the scenic region of eastern Nevada and western Utah. The road is splendidly equipped, the service excellent, and a trip over the newest transcontinental railroad is a real pleasure.

Business conditions throughout the country, whether good or bad, usually find a decided reflex in the mining regions but it may be said that in the San Juan mining districts of southwestern Colorado the present status of the mining industry is largely due to other causes than to the condition of business generally throughout the country. From this statement it must not be concluded that the industry is stagnant in the San Juan. By no means. Nearly all of the larger mines—those which have made that region famous—are still in successful operation and there are a number of new enterprises, which promise a great future, that have only fairly started upon their careers for better or for worse.

My recent visit was the first I had ever been able to make to that noted region, and as usual, notwithstanding the numerous descriptive and illustrated technical and popular articles I had read of the San Juan, I found that there were many things which, to be appreciated, must be seen. No description, it seems to me, can give an adequate idea of the grandeur of those mountains, and photographs, in most instances, fail to give the perspective which will carry a proper idea of their towering heights, while the combination of colors is wholly lost.

Ouray is a good sized town picturesquely situated in the canyon of the Uncompahgre river; almost completely surrounded by vertical cliffs of red and buff sandstone and limestone, which rise a thousand feet or more from the steep talus at the base. From the top of the first scarp of red sandstone, the rocks slope steeply upward to a second line of cliffs, buff, gray, and red in color which add another thousand feet or more to the height of the mountains. Above this is piled layer on layer of dull gray conglomerate, tuff, and massive lava to a height of 2000 to 3000 ft. more, making a total of 5000 ft. or over from the bottom of the canyon to the summit of the ragged sky line. These magnificent mountains present many phases of light and shade with colors brilliant or sombre, according to the conditions of atmosphere, sunshine, and the shadows of clouds. In a hot midsummer day the rocks take on a metallic glare, trying to the eyes and unimpressive, except as to their height. One day in the latter part of last August I stood on the Camp Bird road near the Mineral Farm mine. A heavy thunder shower had just passed and thousands of cascades were leaping down the cliffs on all sides, the rapid run-off swelling the streams in the canyons into raging torrents. The sun was shining through the clouds upon a huge mass of eruptive rock near the Bright Diamond mine, on Gold hill, just beyond Ouray, and the rocks which an hour before had been dull and uninteresting, were now magnificent in the rich color effects produced by the sunlight streaming through the clouds. I only saw one other sight which to my mind surpassed it, when the following day I rode up the canyon of the Uncompahgre, about three miles from Ouray on the road to Silverton. Again the heavy rain clouds had spread like a blanket over the mountains about me, but to the southward in the vicinity of the Red mountains the sun shone brightly. Words cannot describe the gorgeousness of that scene. The mountains were aflame with color. Rich crimson, bright scarlet, dull red, and orange predominated, which the isolated areas of olive green, chocolate, violet, and black set off to wonderful advantage. Mount Abrams on the left is sombre gray on one side, with streaks of gleaming snow near its summit, and Mount Hayden, dark and frowning, on the other, formed a magnificent frame for the splendid picture beyond. A friend of mine endeavored to describe Red mountain to me. He said, "it looks as though some fellow had climbed up there with several barrels of red paint of various shades, and then amused himself by pouring it out on the summit of the mountain allowing it to run at will down the sides of the mountain." I do not believe I can improve upon his description.

On reaching Ouray, one naturally expects to see mines, and is surprised that none is in evidence. Inquiry of the citizens leads to the stranger being directed to scan the summits of those awful cliffs, and there, amid the 'rough and rugged rocks,' 1300 to 2000 ft. above the canyon bed he can with difficulty discern the buildings, looking much like the rocks themselves. The American Nettie, famous these many years as a great gold producer, and a mine of large possibilities yet, is situated high up among those crags nearly half a mile above the town. On a bench 700 ft. lower, the Bright Diamond mine buildings can be seen clinging desperately to the edge of the ragged cliff.

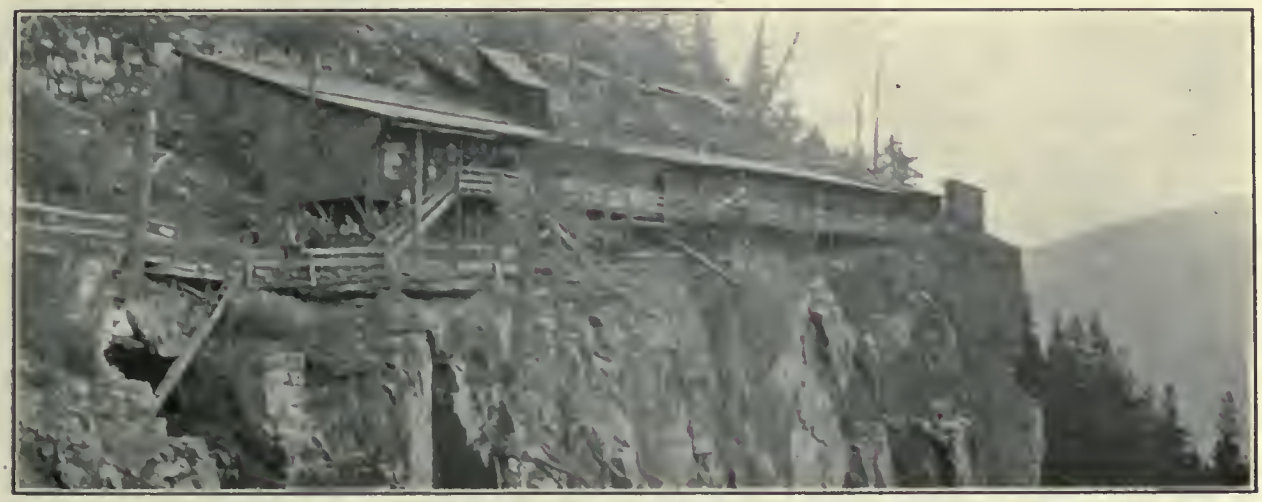
"How do you get up there?" I asked. "By the trail, on horseback," was the answer.

I made the trip, and am free to say a nervous person had better remain down in the village.

The Bright Diamond mine is situated 700 to 800 ft. lower than the American Nettie, and like the latter the ore deposits are found in quartzite, the mineralization occurring at no less than five geological horizons in beds over 100 ft. in thickness. This property is being operated by the Wanakah Mining Co. of Ouray. G. H. Barnhart is manager, and Mr. Roberts, superintendent. The principal development in what is locally called the 'lower contact' is on the Iron-Clad and Finance claims. On the 'upper contact' the openings are on the Bright Diamond claim. The orebodies lie approximately horizontal and extend into the mountain, gaining depth rapidly.

The escarpment of the American Nettie quartzite is from 1500 to 2000 ft. farther east than that of the Bright Diamond-Iron-Clad group and the workings of the American Nettie extend more than 3000 ft. into the mountain, or 4500 to 5000 ft. easterly of the outcrop of the Wanakah company's mines. There seems to be no reason why mineralization on these lower ore-bearing strata should not extend back into the hill at least as far as in the American Nettie above. This, however, remains to be proved by actual development. In addition to the flat sheets of ore, there is in these workings a vertical vein, occupying a fissure in the strata and called the Memphis. It is from one to five feet wide and carries sulphide ore similar to that in the flat deposits. A nearly vertical dike of andesite cuts the sedimentary formations about 200 ft. northerly of the Memphis vein, which in places is accompanied by ore. This dike crosses the canyon of the Uncompahgre, and can be seen cleaving the cliffs for 3000 ft. or more in height. It is known as the Memphis dike, and is thought to have influenced mineralization in the quartzites. Faults are not uncommon in these mines, and in the vicinity, though in most cases the throw is not great. At one place in the mine workings is what seems to be a continuous bed of ore, about 8 ft. thick which along a vertical line shows evidence of disturbance, the ore being crushed and mixed with country rock. On one side of this break the unmineralized rock is quartzite, on the other a partly altered limestone. This is certainly indicative of faulting. Further development should throw more light on this interesting occurrence, the amount of displacement not having been determined.

It is probable that this occurrence affords an illustration of two beds of ore, originally formed at separate horizons, now brought opposite each other by faulting, making them appear to be a single continuous sheet of mineralization. An interesting feature of these deposits, and of the American Nettie as well, is the occurrence of caves in the quartzites along the outcrop, wholly or partly filled with ore. One of these had been discovered a few days prior to my visit and the ore was being removed, little blasting being required. The material filling the cave consisted of a loose, spongy mass of quartz—a skeleton, as it were of an original deposit, presumably of sulphides, in a quartz matrix. As oxidized products were found, hematite, limonite, wad (a mixture of iron oxide and manganese), lead carbonate, and other lead ores, clay, calcite, and both green and blue copper carbonate. Vivianite is seen occasionally. Stalactites of aragonite were not uncommon, and the walls and roof in many places were coated with calcium carbonate now being deposited from seeping waters. Copper sulphate was also found on the roof and walls, and saturating the ore beneath in places. Large pieces of the cellular quartz were removed that were generously bespangled with bright flakes of gold, though these required careful handling, for the gold was loose and was dislodged by a slight blow. Scattered irregularly through the heterogeneous mass of mineral were bunches of sulphide ore, which resemble the unaltered mineral in the quartzite, consisting of the sulphides of iron, lead, copper, and zinc, with gold and silver. Occasionally magnetite is found mingled with the sulphide ores. The horizontal deposits range from a few inches to 8 or 10 ft. in thickness, but are very irregular as to outline, though having a general trend southeasterly into the hill. The sedimentary beds roll somewhat—taking a decided dip along one edge of the deposit, but it is probable that mineralization will be found to continue beyond the roll, along the axis of which the rocks are more dense and show little sign of fracture or crushing—conditions essential to the formation of ore in all such deposits. The Wanakah company has leased the American Nettie stamp-mill situated near the river side of the canyon and was giving it a thorough overhauling. A new aerial tramway had just been completed, and a few buckets of ore had been sent down. Next to a flight in a modern aeroplane a trip in a steel bucket on one of these aerial rope ways of the San Juan should be the most satisfying to those having ambitions in the way of aerial navigation. The Bright Diamond tramway is 2700 ft. long and descends about 1300 ft. vertically. There are but two towers, each near the upper terminal, and none between these and the mill. At one point the



American Nettie Mine, Ouray, Colorado.

bucket swings fully 900 ft. above the canyon bottom. The ore is to be concentrated in the mill when repairs are completed, and very satisfactory results are anticipated.

The American Nettie mine I did not visit as only a few lessees are at work under direction of Frederick O. Seaberg, of Ouray, who told me he considered his prospect of discovering valuable orebodies from present indications as particularly good. There are over 12 miles of workings in this mine, and it has been frequently described by various technical writers, among them T. A. Rickard, in his book, 'Across the San Juan Mountains.' Several million dollars have been taken from these mines of Gold hill, and the deposits are still far from being exhausted though the problem presented today is the economical handling of the large amount of low-grade sulphide ore available in the numerous claims.

About four miles northeast of Ouray is the Calliope mine, one of several on the quartzite that has given fame to this district. The mine is under the management of Carl Sigfried. In the latter part of September it was about ready to make a shipment of ore which was said to carry $8 gold and several ounces silver per ton.

While at Ouray my attention was attracted to several unusual matters. Among them was the four-horse stage which leaves every morning for Silverton. This stage carries passengers and baggage—particularly the latter. The baggage is comfortably arranged and the passengers dispose themselves as best they may. One morning the stage drew up in front of the hotel Beaumont to take on passengers. In front on the foot-board, beneath the driver's seat, was a 50-lb. box of dynamite. A man on the sidewalk who had engaged passage eyed in alarm the label on the box: 'Hercules—40% nitro-glycerine. Explosive—Dangerous.'

"You ain't going to take that powder in the stage?,' he gasped.

"Sure," replied the driver. "The end that explodes—the dangerous end—has been cut off, else I wouldn't pack it, you can bet on that."

This explanation seemed satisfactory, for the man took his seat in the stage with the other passengers, and reached Silverton in safety that afternoon.

In former years there were two smelters down the canyon from Ouray but neither has been in operation for many years. At the site of one of them nothing remains but the slag dump. The ores of the district are sulphide and silicious. Limestone is abundant, and if the smelters could get sufficient ore of their own selection from the mines there seems no reason why smelting cannot be successfully accomplished at Ouray, but the earlier plants evidently had difficulty in getting suitable fluxing mixtures, which with the close competition of those days, made the business unprofitable. Notwithstanding this, there is again talk of organizing a company to build a smelter near Ouray to treat the ores of the surrounding region.

Just south of the town are a number of hot springs which discharge a large volume of scalding water. These springs mostly issue along the line of an east-west fault which has brought the Algonkian rocks up opposite the Carboniferous sandstones. This fault can be traced many thousand feet and at places contains a little ore, but thus far very little ore has been found in any of the fissures occurring in the hard, dense quartzites of those ancient crystalline rocks. There are two other faults approximately parallel with that just mentioned, which have a throw of 50 to 200 ft. Both of them are of some importance where they cross the Mineral Farm property, as the orebodies developed there may possibly be repeated by faulting. The extensions have not been found as yet, no prospecting having been done for them. There is still much opportunity for the prospector about Ouray.

NEW YORK'S WATER PROJECT

The most stupendous municipal water-supply system in the world is that which will eventually supply New York City with water for domestic and other purposes. The magnitude of this engineering project places the largest of Western mining operations, by comparison, in the light of very ordinary affairs. Concerning it, the *Engineering Record*, referring to a recent engineering report to the municipal authorities, says: The Hudson river crossing of the Catskill aqueduct has involved subsurface explorations of such an extensive and difficult character that the detailed account of this portion of the Board of Water Supply's work by Mr. Dodge and Mr. Hoke, not only should prove of great value to others engaged in similar undertakings, but also should be of interest to the engineering profession as a whole, for it records the methods used in determining the location and depth of the deepest inverted water works siphon in the world. After certain preliminary investigations had been made at a number of different points the location for the aqueduct crossing under the Hudson river was fixed at the point where the river narrows in the gorge between Storm King and Breakneck mountains, for at this place the rock was found to be sound granitic gneiss, admirably suited to tunneling. It remained, therefore, to find out how deep the proposed tunnel would have to be driven to remain in sound rock for its entire length and have over it a rock cover of at least 150 ft. This information was obtained by wash borings, by vertical diamond-drill borings put down from scows in the river, and by long inclined diamond borings started from chambers in test shafts about 300 ft. below ground. The longest inclined hole had a length of over 2000 ft.; holes of such depth are unique in this portion of the country, although deeper borings have been made in the Lake Superior copper region and in the South African mining fields. At the Hudson river crossing of the Catskill aqueduct the ledge rock shelves off steeply from both shores, forming a deep notch which is believed to have been gouged out by the action of the ice during the glacial period. This gorge has subsequently been filled in with glacial drift, consisting of sand, gravel, and boulders, the latter often reaching 10 ft. or more in size.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Iron and steel when embedded in conerete do not rust, as the air is excluded from contact with the surfaee of the metal.

Sand-lime brieks are made of 40 parts sand and 1 part lime, enough water being added to make a thiek mortar. This mixture is plaeed in molds and heated by steam under pressure.

Total visible copper supply on September 1, 1910, aeeording to the semi-monthly eireular of James Lewis & Son of Liverpool, was 97,506 tons. This by October 3 had been reduced to 93,961 tons.

Laws relative to the location, possession, and use of water are not as clearly defined as is desirable. The law takes eognizanee of water that flows beneath the surface as well as that upon it.

Unpatented mining claims have been held by the courts to be 'real property' in the strictest sense of the law, and being such are subjeet to assessment and taxation, and may be sold for taxes or under judgment for other debts.

Metallie mercury in tailing is said by some eyanide operators to be an advantage in treatment. In other forms than metallie, however, its presenee is less desirable. Silver-mill and patio tailing eontains mereury in various altered forms, principally as ehloride.

Steel for car wheels is limited to the following as to chemical composition, aeeording to 'Standard Speeifietions' of the Carnegie Steel Co.: carbon 0.65 to 0.85%; manganese, 0.60 to 0.85; silicon, 0.08 to 0.25; phosphorus, not to exceed 0.05; sulphur, not to exceed 0.05.

Flint pebbles are used instead of steel balls in tube-mills where the fine metallie particles due to attrition would be a disadvantage in treatment of the pulp by eyanidation. Where roasting preeedes eyanide treatment all iron partieles are reduced to oxide and are harmless.

Flash-light photographs, partieularly when taken underground, to be successful should have as much light as possible. It is advisable therefore to use a liberal quantity of flash-light powder, or several strips of magnesium tape, otherwise the exposure is likely to be disappointing and much valuable time lost.

Antimony is quoted in New York at 12 to 12¾c. per pound. The reduction of antimony ore is not a simple process. It requires furnaees of partieular construetion, and it is unlikely that the prospector owning a vein producing antimony sulphide or other ore of the metal would make a metallurgieal suecess of the undertaking, to say nothing of eommercial profit.

The strike and dip of veins are governed by no known law, nor does the pitch or trend of an ore-shoot bear any relation to its direetion of dip. There are many who say an ore-shoot will be found to dip to the right when standing on the apex of the vein facing in the direction of dip. This is a fallaey, as ore-shoots may trend either right or left along the plane of the vein, and are frequently known to dip in different directions at various points.

Inspection of a steam-boiler is a matter of importanee. When notified to prepare a boiler for internal inspeetion, proceed to eool down and elean the boiler. Remove all seale, clean out the ashes and soot on the grates and in the eombustion-chambers, and sweep off the plates, heads, and tubes, so that every part of the boiler may be examined and its exact eondition determined. Have the boiler eold for the inspector when he arrives. Have the steam-gauge ready for testing, water-eolumn eonnections open for inspection, and everything in readiness to facilitate a thorough inspection of the boiler and all its conneetions.

Where an association of eight men loeate a plaeer claim of 160 aeres, the law requires the performanee of $100 worth of work, or a like amount in machinery or improvements on the property eaeh year after that in which the location is made. As oil lands are subjeet to entry as placers, this law of annual labor must apply to such oil locations. The law requires annual labor, or improvements, on each claim, but does not speeify the size of the elaim, therefore the holder of a 20-acre elaim or of a fraetional claim of less than half that area is required to expend $100 annually on his claim, regardless of its size, and a claim of 160 aeres requires no more than a small one.

Failure to perform the annual assessment work on an unpatented mining claim is construed by the law as equivalent to abandonment, and the claim then beeomes subjeet to re-loeation by any person, a eitizen of the United States. If A negleeted to do the annual work on his elaim in 1906-7, B had a legal right to re-loeate the elaim in 1908. A's proeedure of serving papers on B eommanding B to cease work on the claim should have been taken into eourt, as A had no legal right to eommand B to stop work. Any work done by B could not be eonsidered as having been done by A, unless A paid for the work. A's only eredit was the four days' work done by himself. If in 1909, while A and B were wrangling over the location, insuffieient annual work was done on the elaim, any third party—C—was legally entitled to loeate the claim for himself. If the 'papers' served on B at the instance of A were in the nature of an order of eourt, B's title would remain unehanged pending a settlement of the matter in eourt, but as B failed to defend his title to the elaim, C had the right to proceed and take legal possession of the property by re-loeation. B may have a just eause of action against A, who eaused him to cease work and thus lose his title to the elaim. Better consult a lawyer.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Avino Mines Company

The Editor:

Sir—In your issue of October 8 I notice in the London letter reference to the Avino Mines of Mexico, Ltd. From the remarks therein one is apt to obtain a wrong impression of the part played by the engineers referred to, A. A. Blow and myself. The property was worked by the Mexicans for several hundred years before it was sold to F. L. Gardner and associates, and a fabulous amount of silver was extracted from the upper workings. Most of the ore taken from the mine under Mexican control was obtained from open-cut work, from the surface down to a depth of 500 ft. Judging from the size of the open-cuts hundreds of thousands of tons must have been extracted. The open-cuts, over 200 ft. in length and, in some places, over 300 wide, would indicate an enormous tonnage. The ore taken from these workings was treated by pan-amalgamation and in patios and was a dry silver ore containing some gold. At the time this property was taken over by Mr. Gardner and others the workings were in sulphide ore, showing two shoots—one of lead and the other of copper ore. These shoots were so thoroughly defined that it was a simple matter to mine the two classes of ore separately, though concentration was required, if a complete extraction was to be considered. I understand this was suggested by Mr. Blow, who was at the time acting as consulting engineer. A concentrating plant was installed and operated for some time. This gave some good results, but the average results were unsatisfactory. I cannot give the reasons for this, but think the poor results were due partly to the inefficiency of the machinery used and, possibly, to the mixture of the different ores going to the mill. There is little data available now to put one in a position to analyze what was done, but I am satisfied that had Mr. Blow's suggestion been carried out carefully the results obtained would have been different. At a later date the concentration plant was thrown out and a lixiviation plant was installed and operated for a considerable time. From the data available and results secured, I judge that this process proved anything but successful. After a series of failures and with depleted funds for operating the property, I undertook its resurrection. In order to do this, I suggested that the then small capital be used to develop the mine laterally and in depth before determining on a method of treatment and all of my earlier efforts were devoted to the development of ore reserves. In the course of this work I was able to ship several thousand tons of copper ore, which netted a nice profit over cost of extraction and furnished about the first profit received from the property. This was after the best ore had been mined and the stopes had been picked over by the previous managements. The ore shipped during the time I acted as manager was taken largely from new development work. After opening up over 100,000 tons of ore and our funds again becoming nearly exhausted, the method of treatment was again taken up. At this time I suggested water concentration, but it was thought advisable to look about for a better method of concentration and after testing a considerable amount of the ore by the Elmore Oil Vacuum process it was decided to give it a thorough trial. An Elmore machine was installed and the ore was thoroughly tested, first with oil, then with oil and acid, and finally by heating the pulp, but the results were, one and all, eminently unsatisfactory. I then tried to persuade the directors to allow me to ship a quantity of ore to H. E. Woods, of Denver, to thoroughly test it by water concentration, but could not get them to agree to this course and I severed my connection with the company. Immediately after that my suggestion was adopted and the ore was sent to Mr. Woods—who tested it without representatives of the company being present—and upon his recommendation an experimental plant was installed some two years ago, so that by now the company should be fairly out of the experimental stage, although this is not indicated by the London letter in question, and it is there suggested that further experiments are advisable.

RALPH NICHOLS.

Gilmore, Idaho, October 21.

Crushing by Stages

The Editor:

Sir—In your issue of July 30 I took exception to Felix Cremer's remarks in regard to the mining fraternity not recognizing the efficiency of the principle of grinding as illustrated in the conical tube-mill. I made some criticism of the principle involved mainly for the purpose of getting accurate data from metallurgists who have the two types of machines, cylindrical and conical, working side by side. The results on which I based my opinion were, as Mr. Cremer suggested, not recorded with sufficient accuracy to preclude errors of judgment and as the two types of machines were not used, no comparison was available. Mr. Cremer has offered no figures nor any mathematical deductions to prove his point.

Then comes Stuart Tod, who supplies concrete figures of an actual comparison of two mills working side by side on the same ore. This is the kind of information that is wanted. The comparative efficiency of the two mills is herein worked out. H. W. Hardinge, the professed parent of his 'baby,' as he calls it, enters into the discussion, October 8, but offers no figures of actual work done. I am surprised at some of the mathematics he has offered. I was unaware that all of the surface of the balls introduced into a tube-mill was effective crushing surface, for I had labored under the delusion that the balls only touched at points, and not over their entire superficial area, which renders Mr. Hardinge's mill '13,000 times' more effective than stamps of a weight equivalent to the weight of balls in his conical mill.

Doubtless Mr. Hardinge has authenticated figures which represent the actual (not theoretical) performance of his mills, and if these were published much needed light would be thrown on the subject. I notice Mr. Hardinge takes exception to Mr. Tod calling his mill a single-cone mill. This is unfortunate, for if the principle involved is correct there should be a central feed and double discharge, as Mr. Abbé has developed his double conical mill. Why? Because if this sizing action is pronounced the tendency must be to keep the fine material at the feed end and to push the coarser material in the opposite direction—forcing this coarse material to that portion of the cone where the crushing efficiency is at its lowest. In other words, the heavy stamp has missed the coarse ore and the light stamp must attempt to do this work at a disadvantage. (Note Mr. Hardinge's comparative illustration of stamps in the tube-mill.) This point is proved by Mr. Tod's figures, 15.1% + 20-mesh, the feed, and 3.5% + 20-mesh, the discharge, showing that 3.5% of the ore passed entirely through the mill without any reduction in size.

I do not agree with Mr. Hardinge that I take the position that the body of his mill "is formed on correct lines." I believe the nearer it approaches the cylindrical, the more effective it would be, but I did suggest in *The Mining World* that provided the sizing action was pronounced, as claimed, that an ellipsoidal-shaped mill would be more effective than the conical because it gave more 'large diameter.' A mill, to be effective, must revolve at a speed proportionate to its diameter, or, as the formula shows, inversely as the square of the diameter, the variation in speed due to load of pebbles, physical quality of ore, etc., being secondary. A conical tube cannot conform to this condition, because all diameters make a revolution in the same time, but not at the same peripheral speed.

I have recommended two mills or more, and intermediate sizing not, as Mr. Hardinge states, using the same media, but mills of different diameters, different size pebbles, and different speeds. This is a different proposition. To analyze Mr. Tod's figures, it may be supposed that the mean grade of ore remaining on a 20-mesh screen to be that corresponding to the average of the sizes between 10 and 20 mesh, that on a 40-mesh to be an average between 20 and 40, and so on, and that going through 120-mesh as the mean between 120 and 200. The figures will be as fair for one machine as for another. The sizes of the apertures in the different mesh screens may be taken as follows, calculated as in Richards' 'Ore Dressing.'

+ 10 mesh	0.0205 inch
+ 20 "	0.027 "
+ 40 "	0.0115 "
+ 60 "	0.0072 "
+ 80 "	0.0057 "
+ 100 "	0.005 "
+ 120 "	0.004 "
+ 150 "	0.0036 "
+ 200 "	0.003 "

"The problem becomes the mathematical one of determining the relative surface of the grains of pulp before and after passing through the tube-mill, assuming similar shapes and equal weights of all the particles included in each successive grade. Since for any definite weight of ore the total surface area varies inversely as the diameter, then the relative surface exposed by each grade may be determined by dividing the weight of that grade by the average diameter of the particles in the grade."

COMPARATIVE EFFICIENCY TABLE

Cylindrical Tube

Mesh.	Mean grade.	Feed. %	Feed. Relative surface.	Issue. %	Issue. Relative surface.
+ 20	0.023	3.1	1.34	....	....
+ 40	0.019	15.5	8.15	3.2	1.63
+ 60	0.009	15.6	17.33	4.5	5.00
+ 80	0.006	14.6	24.33	10.5	17.50
+ 100	0.005	9.6	19.20	15.8	31.60
+ 120	0.0045	2.4	5.33	2.4	5.33
— 120	0.0035	39.2	112.00	63.6	181.71
			187.68		242.77
					187.68
					55.09

Conical Tube

Mesh.	Mean grade.	Feed. %	Feed. Relative surface.	Issue. %	Issue. Relative surface.
+ 20	0.023	15.1	6.56	3.5	1.51
+ 40	0.019	55.6	18.78	21.2	11.15
+ 60	0.009	10.4	11.55	14.1	15.66
+ 80	0.006	11.1	18.50	17.9	29.83
+ 100	0.005	6.4	12.80	11.2	22.40
+ 120	0.0045	0.7	1.55	1.6	3.55
— 120	0.0035	20.7	59.14	30.0	87.14
			128.83		171.24
					128.83
					42.41

I have divided the product by 100 to bring the calculations to unity. The relative mechanical efficiency is obtained by dividing the work done by the amount of power used. The cylindrical tube has reduced the surface 55%; the conical tube 42.4%. If the power and tonnage were the same the relative work done would be as 55 to 42, but while the tonnage is the same the power required is different.

$$\text{Work done, cylindrical, } \frac{55 \times 75}{30 \text{ hp.}} = 137.5$$

$$\text{Work done, conical, } \frac{42.4 \times 75}{25 \text{ hp.}} = 127.2$$

This shows the relative efficiency of the cylindrical and conical mills as calculated from Mr. Tod's figures of actual work accomplished, to be as 137.5 to 127.2.

ALGERNON DEL MAR.

Fort Bidwell, California, October 15.

COST OF POWER PER HORSE-POWER DAY*

Steam-power, non-condensing engines, coal at $4.50 = 16 — 18 cents.

Condensing engines = 14 — 16 cents.

Compound condensing engines = 11 — 14 cents.

For each $1 increase in cost of coal add 1½, 1¼, and 1c. respectively.

Electric-power, $40 — $65 per yearly horse-power = 11 — 18 cents.

*J. A. Barr, 'Testing for Metallurgical Processes.'

Special Correspondence

PITTSBURG, PENNSYLVANIA

First Mine-Rescue Car Arrives.—Men Being Trained.—Illinois Stations Rushed to Completion.—First Aid Work.

Mine-Rescue Car No. 1 of the U. S. Bureau of Mines was delivered at the Pittsburg station recently, where it will be completely fitted for emergency calls and systematic training in rescue methods and first-aid relief. This is an indication of the efforts being made by the Bureau under recent legislation. The malden trip was the occasion for bringing to Pittsburg the Illinois men who are in training for positions at the three State stations now under construction. On arrival of the car at Urbana station it was inspected by State mine inspectors and members of the State commission for mine rescue work. It is a re-built Pullman, with berths and arrangements for meals for ten men, including the two in charge. One-half of the car has clear floor-space for equipment and for demonstration work, but has upper berths which are lowered for use at night or as temporary hospital quarters. Similar cars will probably

Mine Rescue Car, U. S. Bureau of Mines.

be purchased by the State of Illinois for auxiliary work. The car was in charge of R. Y. Williams, mining engineer, and J. M. Webb, foreman of the Urbana station. F. W. DeWolf, State geologist, accompanied the party, which included the following men who have completed preliminary training at Urbana: Charles Swan, G. H. Walmsley, Peter Donnelly, J. C. Duncan, Frank Rosbottom, and Thomas English. These men are in training for places in Illinois stations as superintendents and assistants. Three State stations to cost $11,000 are being built. It is hoped they will be finished and equipped January 1, 1911. On arrival at Pittsburg the men joined the Federal corps and other miners from Pennsylvania, Alabama, Indiana, and elsewhere, assembled for instruction in rescue work or engaged in the scope of the investigations under way at the Pittsburg station. Dr. Shields, well known for his efficient work in organizing and training first-aid corps in the anthracite region, was present and gave daily instruction and demonstrations of methods. His corps of six men served as a stimulus to others in training. The complete course of training will require a week or ten days. At the close of the meeting it is expected that the men will scatter to various Federal and State stations to spread the benefits which follow systematic rescue and first-aid instruction. Other special cars—six in all—will be delivered at once, and buildings at various sub-stations will be rushed to completion as soon as possible in order to guard against the mine accidents which usually are more numerous and serious during autumn and winter months. Illinois is the first State to take up the work independently. It will there be in charge of a commission, which has recently selected Richard Newsome, of Peoria, as general superintendent.

BULAWAYO, SOUTH AFRICA

Important Consolidation of Rhodesian Mining Properties.—Geological Survey for Southern Rhodesia.—New Companies.

One of the most important projects that has ever been launched in connection with Rhodesian mining is now being arranged in London, and by this time it should be completely arranged. The scheme in question is the formation of a Rhodesian trust company which will control the fortunes of a number of important mining and financial undertakings; will finance these concerns, and advance the development of the several mines. The new company, which will in reality be a reconstruction of the Rhodesian Exploration & Development Co., will have cash in hand to the amount of over £4,000,000, and should prove a 'tower of strength' to mining enterprise in Rhodesia and likewise greatly increase the stability of the industry. It is proposed to increase the capital of the Rhodesia Exploration & Development Co. from £450,000 in £1 shares (of which 350,000 are in issue) to £2,000,000 and to acquire the whole of the interests at present held by the Rhodesian Banket Co., the Rhodesian Abercorn Shamva Trust Co., the Etna Development Co., the Gold Schists of Rhodesia, Ltd., the London & Johannesburg Trust Co., the London & Johannesburg Syndicate, and the French S. A. Development Syndicate, Ltd. These companies will receive between them 1,407,299 shares in the new trust and the allocation of the remaining capital will be as follows: 300,000 shares will be offered to shareholders in the above mentioned companies and syndicates at 45s. per share. These have all been guaranteed by Abe Bailey, the moving spirit in the new enterprise. The remaining 292,771 shares will be held in reserve. The chief objective of this re-shuffling of the cards is to provide ample funds for the development of the several important mines concerned in the reconstruction. The blocking out of further reserves of ore is an urgent need in Rhodesia today, for the number of mines in possession of any really substantial tonnage in sight is comparatively small. Until quite recently the majority of Rhodesian mining companies were content to produce in a very hand-to-mouth manner, and it is only during the last two or three years that any really serious endeavors have been made to place Rhodesian properties on a sound and business like footing in so far as development is concerned. The number of mines possessing air-compressor plants is still small, but it is satisfactory to note that two or three air equipments have recently been installed and that the question of erection of other installations is receiving attention. With the large sum of money placed at its disposal by the new reconstruction and absorption scheme the Rhodesia Exploration & Development Co. should be able to place the mines which are being acquired on a satisfactory basis in regard to development. The promoters of this scheme anticipate, indeed, that its consummation will impart to Rhodesian mining affairs an inherent soundness and stability similar to those conditions which have resulted from consolidation of interests among the mines of the Witwatersrand.

H. B. Maufe, who has been appointed head of the Geological Survey of Southern Rhodesia, has arrived in Bulawayo, and after a few days' stay here will proceed to Salisbury to confer with the administrator on the subject of his new work. The Geological Survey has only recently been sanctioned by the British South Africa Co., although it has long been realized that there was urgent need for some thoroughly scientific examination of the numerous mineral belts of Matabeleland and Mashonaland, and for a proper classification and delimitation of the varied and complex strata of the country. It is doubtful whether there is any other territory in the world in greater need of a Geological Survey than Southern Rhodesia. The great majority of

the country's mines have, as is well known, been opened on the sites of ancient workings—workings resulting from the activities of Phenician adventurers, or the early Portuguese invaders. The amount of prospecting work that has been carried out in 'virgin' country has been very small, and in view of what is known today of the gold belts of Southern Rhodesia and their wide distribution and of the general geological characteristics of the country, it does not seem a rash statement to assert—as it often is asserted by the more intelligent prospectors in the country—that Rhodesia has so far merely been 'scratched' and that there are vast mineralized areas awaiting exploration. Mr. Maufe's work will then, it may be confidently expected, result in the obtaining of much valuable data, valuable from an economic as well as a scientific point of view. New companies are being constantly formed for the purpose of acquiring and working Rhodesian ventures, and among the latest flotations is the Don Proprietary mines with a capital of £75,000 in £1 shares. The company has been registered to acquire the Don, Peggy, and Scouts mines in the Gwelo district of Matabeleland. The company has over £20,000 cash at its disposal as working capital, which in view of the fact that two of the mines, the Don and the Peggy, are already equipped with stamps and cyanide plant and that the Scouts mine will shortly be the subject of a subsidiary flotation, can be devoted chiefly to the prosecution of further development. The expenditure on the Don mine to date has been £25,000 and on the Peggy £15,000. The properties have been inspected and reported on by Clement Dixon, M. I. M. M., consulting engineer to the company, and influential Rhodesian and London boards of directors have been got together. The head office of the Don Proprietary mines is at Gwelo, Matabeleland.

TORONTO, CANADA

Discontinuance of Iron and Steel Bounties. —Condition of La Rose.—Other Cobalt Bonanzas.—Porcupine.

The Canadian Government, it is announced, has finally determined not to renew the iron and steel bounties or to give an equivalent in the way of additional tariff protection to those industries. The question was left an open one when the termination of the bounties was decided on last session, though W. S. Fielding, Finance Minister, warned the iron and steel men that it was not likely that any further protection would be granted. The attitude of the Government has probably been largely influenced by the growing free-trade or tariff reduction sentiment of the Western farmers, so strongly manifested during the recent visit of Sir Wilfrid Laurier and his colleagues to the West, and a consideration of the increased representation in Parliament to which that section will be entitled on the redistribution of constituencies on the basis of the census of 1911.

The withdrawal of the bounties is a serious matter for the large steel industries, as the total amount distributed in this form during the fiscal year ended March 31, 1909, amounted to $1,864,000, over one-half of which went to the Dominion Steel Corporation of Sydney, N. S. This company has for some time been shaping its policy in view of the threatened depreciation of revenue. It is increasing its productive capacity by about one-third by extensions now completed or in progress, in order by increased sales and the diminished cost of production on a large scale to make good the loss, and J. H. Plummer, the president, announces that further extensions are being arranged for. The bounties on pig-iron and steel ingots terminate with the present year; the payments on wire rods continue to June 30, 1911, when they also cease. It is the present intention of the corporation, according to Mr. Plummer, to discontinue wire-rod manufacture and substitute other forms of finished steel, as he does not believe that Canadian manufacturers, in the absence of protection, can compete in this line with their rivals in the United States and Belgium. The salient feature in connection with Cobalt is the marked advance in La Rose during the last few days, consequent on the publication of the annual report with a very favorable showing, accompanied by later reports of an important find in the mine. The report covering the fiscal year ended May 31, gives the total product at 3,170,028 oz. silver of the value of $1,472,005, produced at a cost of 23.27c. per oz., including the expense of development work. The shareholders received $900,000 in dividends or 12% on the capital, after providing for which there remained a combined surplus of the holding and operating companies amounting to $473,740. The ore reserves on the La Rose proper are estimated at 5,544,000 oz., an increase of 576,000 oz. over the previous year's estimate. The Temiskaming is another company whose position has much improved lately. The payment of dividends, discontinued last year in order to obtain funds for the installation of a concentrator, has been resumed at the former rate of 3% per quarter. The mill is now making $1000 per day over expenses from the large accumulation of low-grade ore taken out in the course of development. Work is being carried on at the 500-ft. level to catch the ore-shoot worked on the upper levels. A report made by the Crown Reserve of the operations of the nine-month period ended September 30, showed a revenue of $1,150,303. operating expenses $184,128, and royalty $108,889, leaving net profits of $857,286. Out of this amount $795,966 was paid in dividends, leaving a balance of $61,320. The total surplus on hand was $610,595. The Trethewey has resumed dividend payments, declaring a 10% dividend, after providing for which and covering outstanding liabilities it has a surplus remaining of $102,759. Gould Consolidated, the stock of which has been on the bargain counter for some time, is looking up. The finding at the 300-ft. level by diamond-drill of a vein rich in silver is reported. A shaft will be put down on this vein. The Silver Bar is another mine that has been regarded as a 'dead one' and is showing signs of recovery. It has been closed for about a year, after bagging considerable ore, having an outstanding indebtedness of $35,000. A syndicate is being formed to pay this off and raise money for operating expenses, but there are some legal complications in the way. The property of the Cobalt Central, now in liquidation, is to be sold by auction December 28. The Porcupine camp is apparently on the eve of a boom and is receiving a good deal of attention from British and American investors and mining brokers. The Consolidated Gold Fields Co. of South Africa is in the field, and has secured two properties, having a combined area of 320 acres in a central portion of the camp. On one of these a rich vein, averaging 12 to 15 ft. in width and carrying free gold, have been uncovered for 200 ft. The advent of this company is considered an important event as foreshadowing development on a large scale. It is stated that the Dome company has about 500,000 tons blocked out. The first mining flotation for several months has been made here this week by the United Porcupine Gold Mines, Ltd., capitalized at $1,500,000, of which 500,000 shares of the par value of $1 are being offered at 10c. each. According to the prospectus the balance of the shares has been issued in payment for the property. If the public prove sufficiently receptive it will doubtless be followed by others of a similar character. The experiment of placing on the Ottawa market the peat-fuel manufactured at the Government peat plant at Alfred, Ontario, under the direction of the Mines Branch, has been successful. A consignment of 500 tons was quickly bought at $3.25 per ton and the consumers were so well satisfied that a great many orders for further supplies have been received. The general opinion among those who have tried the peat fuel is that it is cheaper and gives more satisfaction than coal.

LONDON

Development in West Africa.—Tasmania Gold Mining Co.—Conditions at Kalgoorlie.

Recent development work at Cinnamon Bippo and Wassaw mines in West Africa has necessitated a revision of the estimated ore reserve. At the former the reserve on June 30 was 241,669 tons averaging 7.81 dwt. as compared with 208,809 tons on March 31 averaging 10.13 dwt., while at the latter the reserve has risen from 202,916 to 237,442

tons, but the average has fallen from 10.65 to 8.39 dwt. No ore is being extracted at present, as operations are centred on development. It will be seen on analyzing the figures that the total gold content is less now than three months before. This is due to the orebodies being found to be much more broken than was at first supposed.

The Tasmania Gold Mining Co., one of John Taylor & Son's group, is to be reconstructed with an assessment of 2s. 6d. per share which will yield additional capital amounting to £62,500. The company was formed in 1903 to consolidate various gold mines in Tasmania that had become unprofitable owing to the great volume of water coming into the deeper levels. After installing a gigantic pumping plant the company produced large amounts of gold yearly, though without making any distributable profit. A year ago the average content fell, causing a loss on operations. As the orebodies are promising at depth, the directors now advise the raising of this additional capital to continue operations. As already recorded, the production at the Golden Horse-Shoe at Kalgoorlie has fallen recently. At the meeting of shareholders in May the directors promised a special report by the manager, J. W. Sutherland. This has now been issued. His estimate of the ore reserves revised on June 30, gives 903,592 tons averaging 10.32 dwt., as compared with 1,071,638 tons averaging 11 dwt. on December 31 last. The decrease in the tonnage is accounted for solely by the extraction of ore for the battery and not by the rejection of any parts included before. At the same time the reserve has not been increased, as the development work done during the half-year has been preparatory rather than final. The ore mined during the half-year has averaged 10½ dwt. It will be seen that the revised estimate does not reduce the content to the extent expected by many. Mr. Sutherland attributes the recent fall in the output to a combination of factors. First, some of the stopes were in poor ground, second at other points the vein was more faulted than was expected, and third, it happened that mining could not be done at some other points where the ore was known to be richer. In addition a few breakdowns of machinery occurred, in themselves of no great importance, but taken in conjunction with the other circumstances caused further restriction of the output. Mr. Sutherland writes hopefully of the future. The directors have requisitioned the services of Henry Kuss, the French inspector-general of mines, who will proceed to the mine to make an independent examination.

KALGOORLIE, WESTERN AUSTRALIA

Lectures by T. W. E. David.—Conditions on the Golden Mile.— Output for August.

During the past week we have had a series of lectures in Kalgoorlie by T. W. E. David, demonstrator in geology and allied subjects at the Sydney University. The lectures were: (1) 'The Shackleton Expedition to the South Pole'; (2) 'The Journey to the South Magnetic Pole'; (3) 'Mexico—Past and Present'; and (4) 'The Origin of Ore Deposits, and Remarks on Artesian Water.' Mr. David was with the Shackleton party in 1907-09. He and three others were the first men to ascend the active volcano of Mt. Erebus, 13,000 ft. high, and also to locate the south magnetic pole. He did not participate in the final dash to the south pole. In 1906, Mr. David went as a delegate to the International Geological Congress at Mexico City. As far as geology is concerned he is both a thinker and a worker, and has studied Australian conditions closely. All the above lectures were illustrated by fine lantern slides. In connection with the first subject, the lecturer explained the manner in which one should dress, eat, and drink in such cold latitudes; the difference between icebergs and snowbergs; he showed slides of several fossil plants and leaves, identical with those found in Australia; he said that granite, limestone, schist, and coal seams exist in Antarctica. The coal gave on analysis 68% of fixed carbon, and may some day be of economic value. The second lecture was somewhat on the lines of the first, but details of the locating of the south magnetic pole were given. The lecture on Mexico was especially interesting, the lecturer going deeply into the history of the country and its present state under President Diaz with the great improvements in Mexico City and other towns, irrigation and electric power schemes, the geographical, geodetical, and geological surveys in progress, meteorological observatories, and touching lightly on the mining industry. 'The Origin of Ore Deposits' was an unusually interesting discourse, illustrated by pictures, maps, and rock sections. Mr. David began with a consideration of the old theories of the earth's formation. Norman Lockyer held that the earth had been formed by a number of meteorites flying through space, and coming in contact with one another when traveling at a terrific speed, had become fused together. T. C. Chamberlin, of the Chicago University, propounded the planetesimal hypothesis, and assumed that this process was still going on, and at the present day the earth was getting bigger and heavier. It was calculated that 100 tons (an unknown quantity falling into the sea) of meteorites fell upon the earth every year. Probably 500,000 tons of meteoric dust fell on the earth annually. During the South Pole Expedition experiments were made to substantiate this dust theory by taking a carefully weighed quantity of pure snow and finding the percentage of solids contained. A surprising amount of fine dust was found. Meteorites are cold in the interior, but hot on the outside on account of the friction due to rushing through the earth's atmosphere. Through the accumulation of meteoric material, great pressure is held to have developed, and the hollows been gradually filled. From the

Part of Oroya-Links Dump Now Being Treated.

evidence of earthquake phenomena, Mr. Chamberlin adduces strong proof of the correctness of his theory. Seues has accepted the Chamberlin views. In discussing volcanoes Mr. David argued that in eruptions there were three stages: (1) at the height of eruption when everything was extremely hot, and hydrogen, oxygen, and chlorine were emitted, the two former combining to form water, which came down to earth in the form of rain, this water having never seen the light of day before. (2) The eruption cooling off somewhat, when sulphur and arsenic were emitted. (3) The quiescent stage when large volumes of CO_2 were given off, as occurs in certain spots on the earth at the present time, and carbonaceous material was formed. Solutions eventually were formed, which filled in the cracks on the earth, gradually leading to the formation of metalliferous lodes. In the Associated Northern Blocks, the Ivanhoe, and Great Boulder mines at Kalgoorlie, at depths from 500 to 2650 ft., Mr. David had seen carbonaceous mineral in the form of graphitic slate and schist, bearing out the theory of the CO_2 coming up from great depths, and forming these minerals. In the first-mentioned mine, methane had been and is still occasionally given off in quantity. Regarding the lodes at Kalgoorlie, Mr. David considered them intensely interesting, and demanding much research, such as has been done by Messrs. Gibb, Maitland, Larcanbe, Gibson, Maclaren, Woodward, and others. During the lecture, pictures and sections were shown. Among others were the Mt. Morgan mine; the Broken Hill lode and mines; the lodes at Joachimstahl, in Bohemia, Austria; the Bendigo saddle-reefs (after Rickard); the Ballarat Indicator; and sections of the country in Central and Western Australia. While

there is a great area of artesian water in Australia, there is not enough for purposes of irrigation. Wells must not be sunk too close together or one would rob the other. The popular idea of artesian water basins was explained, and the real formation shown and proved by experiment. There were springs in the limestone cliffs at Eucla in the Great Australian Bight; and Mr. Woodward, one of our geologists, decided to sink a bore for water in the Permo-Carboniferous rocks in the northwest of this State. Geologists were astounded, but the well was sunk and developed a large supply of water. Altogether, the series of lectures was most profitable and interesting.

This is the season when for the next six months the wind is strong, and tailing is blown all over the place, making work disagreeable near the mines, besides damaging plant and machinery. Some of the sand heaps have been sprayed with salt water, which forms a crust over the tailing. At other places the material is being re-treated and pumped into ponds. The Perseverance company is using the South Kalgurli heap for stope-filling. The Lake View & Star is the latest to install machinery to pump away its tailing. At one time the dumps were great landmarks, but one by one they are being removed. In development profitable ore has been cut at 2650 ft. in the Great Boulder, at 1850 ft. in the Kalgurli, and at 500 ft. in the Lake View & Star mines since my last notes. It is probable that there will be a drop in the Oroya Links output next month, as the Eclipse mine cannot keep the 50-stamp mill fully employed. As affairs are now the Associated, Associated Northern Blocks, Chaffers, and Oroya Links may be classed as having poor prospects.

Only $38,500 was paid in dividends for August, but $475,000 has been declared for September. The gold output for the month totaled $2,470,000, and the yields from the principal producers were as follows:

Name.	Tonnage.	Value.	Profit.
Associated	10,853	$73,500	$1,600
Associated Northern Blocks	2,500	29,000	16,500
Chaffers	4,413	33,500	3,450
Golden Horse-Shoe	23,867	170,000	800
Golden Ridge	2,400	31,000	14,000
Great Boulder Proprietary	19,048	244,500	123,000
Great Boulder Perseverance	†13,138	83,000	‡7,800
Great Fingall	10,887	82,500	13,000
Hainault	6,150	38,500	5,500
Ivanhoe	19,622	205,000	100,000
Kalgurli	11,060	142,000	76,500
Lake View Consols	*9,385	7,900	1,950
Lake View & Star	12,070	70,000	‡18,000
Oroya Brownhill	*21,945	26,500	13,500
Oroya Links	10,902	67,500	8,500

Sons of Gwalia	13,510	118,000	45,500
Sons of Gwalia South	2,432	23,000	8,000
South Kalgurli	9,350	61,500	8,500

*From old dumps. †First return from new mill. ‡Loss.

BUTTE, MONTANA

Development of Deep Levels in Important Mines. — Tests of Montana Coals.

What is known as the Tramway shaft of the Red Metal company is being deepened and a station is being cut at the 2000-ft., where another level will be opened. Extensive development is going on in the Rarus mine, another Red Metal property, and that mine is again yielding good ore. Development at the Right Bower group has been practically suspended, as its purpose has been accomplished, namely, to prove the ownership of the disputed vein on which the Butte Ballaklava company was mining, and on which it has been enjoined by the court. That the Butte Ballaklava ground contains other good veins not in dispute is admitted by officers of the Anaconda company. The Butte Ballaklava company is doing much development and has opened another fine body of ore on the 700-ft. level.

The North Butte and the Tuolumne company have renewed activity in preparation for the coming trial. It is understood that offers have been made to some of the large stockholders of the Tuolumne for a purchase of a controlling interest by the North Butte, but these stockholders refused to sell unless the stock of some of their friends was purchased. There was also a difference between the North Butte people and the Tuolumne officers as to the value of the Tuolumne fractional claim. The Tuolumne people wanted to sell at a rate of $8 per share for the 800,000 shares of stock, while the North Butte offered, in exchange of stock, about $4 per share. Reports from the Raven mine indicate a probability that the patience of Raven stockholders is to be rewarded. Some high-grade copper samples have come from the 1300-ft. level, the first ever found in the mine. A new level is being opened at the 1500, and if the ore is found at that depth it is almost a certainty that the Raven will develop into a good copper mine.

At the Washoe and Great Falls smelters tests have been carried on for some time with Montana coal with the idea of substituting it for Wyoming coal, and to use coal fire direct at the Great Falls smelter instead of deriving heat from coal gas, as at present. The shaft of the St. Lawrence mine is being repaired, and new ore-bins are being built, to be completed in six weeks. Cross-cutting and driving is going on at the Badger State mine, with good results, and sinking is being pushed at the new Gagnon shaft and at the four-compartment shaft on the Belmont, which has reached a depth corresponding to the 2100-ft. level of the Anaconda mine, with which it is being connected on each level. At 2400 ft., the Belmont shaft will be connected with the deepest level of the Anaconda mine and will be used as an auxiliary shaft. It will also improve ventilation in all the Anaconda Hill mines. It is situated about a mile south of the main shaft of the Anaconda and is the largest shaft in the district.

SALT LAKE, UTAH

Important Changes in Management. — New Mill for Park City. — Ontario to Resume.

Two personal items of interest have been announced within the past few days: D. C. Jackling, manager of Utah Copper, has been appointed manager of all Guggenheim interests in the Western United States, Mexico, and Alaska, and Colin McIntosh, manager of Ohio Copper, has resigned and will devote his time to his private interests. Mr. Jackling has been at the head of Utah Copper since it was scarcely more than a prospect and has brought it to the position where it is one of the largest producers in the world. Mr. McIntosh took charge of Ohio Copper when the control passed to the Heinze interests. In addition to developing the mine and building the mill he has carried the company through a very trying financial period and has brought it into the producing class. With the completion of the mill, only one-half of which is in operation, Ohio will be one of the large producers of the world. The methods and systems which Mr. McIntosh installed in both mine and mill will not be altered by the new manager, Al Frank, who has been chief engineer on the Heinze staff. The Starlus group in Bingham has been bonded for $800,000 to Eastern capitalists. The group lies next to the Utah Copper and is owned by E. A. Wall, one of the original owners of the latter company. The Grasselli Chemical Co., which operates a mill at Park City for the treatment of zinc tailing, is building a new mill on the flat north of the town. This plant, which will have a daily capacity of 125 tons, will treat an accumulation of old mill tailing along Poison creek. The accumulation is 3500 ft. long, 500 to 1000 ft. wide, and has an average thickness of two feet. H. M. Crowther has taken a lease on the Ontario mine and will probably operate it more extensively than at any time since the drain-adit caved some years ago. It is not likely that the company will operate the mine again unless the lessees open some large bodies of ore at present unknown. The Ontario has produced $45,000,000 and paid $15,000,000 in dividends, the largest of any silver-lead mine in the country. The old 'bogy' of the Success mining deal will not

down, and another suit has been filed against Jesse Knight and others for an accounting and restoration of rights. The claim is that Knight secured control of the Success, merged it with Colorado, and canceled a large number of stock certificates on the ground that an assessment (notice of which was never given) had not been paid. This is only one of several suits that have been and will be filed. C. A. Pringle, manager for the Tintic Mining & Development Co. and for the Yampa Smelting Co., has resigned that position and has been succeeded by J. W. D. Moodie, of Los Angeles, and formerly of Park City. Sioux Con. has declared its regular quarterly dividend of 4c., bringing the total within the last two years up to about $800,000. The company has a cash balance, after deducting the dividend, of over $65,000. After four months of shut-down the Mammoth is ready to resume operations at regular capacity. The wrecked hoisting machinery has been replaced and the shaft largely re-timbered. The cable is on hand and all that remains is to string it and finish timbering the shaft. The Scanton mine in North Tintic has made a find of a good sized body of zinc carbonate. The company is mining 600 tons of zinc ore per month and shipping it to Wisconsin. A deposit of antimony has been opened at Antimony in Garfield county, but no shipments have been made, as a suitable method for treatment has not been found. This ore contains gold, and experiments have been made with the Masson method of treatment by which antimony is extracted by a chemical process and the tailing cyanided for the gold. A project which will mean much to the camp of Alta, if carried out, is the Alta & Jordan Valley railroad, which recently filed articles of incorporation. Alta possesses much good mining ground, but freight rates are high and the camp is isolated for several months each year on account of snow. A railroad would be a great help to the camp. The Hornsilver, in Beaver county, is planning to build a concentrating mill of 100 tons daily capacity this winter. The company has been making extensive tests to determine the best method of treating the ore and will doubtless remodel the old mill at the mine. There is considerable low-grade ore stored in the old stopes and drifts and also a large tonnage that has never been mined.

NEW YORK

Conditions in Wall Street Improved. — Copper Going Up. — The Ray Central Deal.—El Rayo.

The bull campaign now in progress on the New York Stock Exchange is assuming well-grown proportions. The ostensible head of the movement is the house of Eugene Meyer Jr. & Co. Steel has been used as a leader. It has been marked up to 80⅛ and is evidently to be put still higher to induce public interest. Other elements are assisting the rise in prices. The political situation is the largest market factor. Wall Street is professing a strong belief in the defeat of the Roosevelt forces, and a large part of the present campaign is built up on the theory that the New York State election will result in a defeat for the growing and supposedly dangerous radical theories of Mr. Roosevelt, and a big triumph for the safe and sane treatment of corporations. In a sense, therefore, the present market is an appeal to public sentiment. The dangers to which market operators are exposed are consequently obvious. The copper metal market is in a fair way for complete recovery, though it seems to be understood that it will not be allowed to soar with consequent disastrous reactions. The market is reported as sold ahead; the three largest agencies, United Metals, Phelps-Dodge, and the Guggenheims, are all quoting 13 cents with nothing for delivery until after January next. Killing off the consumer with 25-cent copper is directly responsible for the accumulated surplus which has clogged the market. The General Development Co. has come in for sharp criticism on account of the Ray Central deal. When the $100,000 of bonds was taken by the Development company, it also had an option under which it acquired, at $1 per share, 200,000 shares of stock. All of this, it is said, has been peddled out as the market would take it during the past few months at three and four times the option price. At the meeting of the Development company held this week the board, acting upon the advice of J. Parke Channing, resolved to reject the Ray Central option, and the Lewisohn representatives on the Ray Central board sent in their resignations, to become effective upon the election of their successors. Just what steps the Philadelphia men, who are now again in control of Ray Central, intend to take has not yet been announced. It is looked upon as certain that eventually the company will be absorbed by the Ray Consolidated, though in all likelihood there will be some independent development done in the meantime. The Philadelphia contingent has been a heavy buyer of the stock since the position of the General Development Co. has been made public, and this is thought to be an indication that some deal may be made in the future. The directors resigning from the Ray Central board were Julius Lewisohn and Alvin Untermeyer. Oscar A. Turner, who was formerly connected with the Ely Central Copper, also resigned from the Ray Central board and was succeeded by J. B. Cummins. The bonds of the Braden Copper Co., recently authorized, have been underwritten by Eugene Meyer Jr. & Co. at 95, and stockholders may subscribe to the extent of one-sixth of present holdings. The mill is expected to go into operation in July next. Federal Mining & Smelting is in a bad way. Preferred sold this week at 37, a new low record. It was 112⅞ in 1906. The common sold at 12, as against 199 in 1906. When the American Smelters Securities Co. took over the control of the Federal the common was about $100 per share. The new directorate of the Granby Con. has semi-officially announced a resumption of dividends on a basis of 1% quarterly. Samuel Newhouse has become identified officially with the South Utah Mines & Smelters, a reorganization of the old Newhouse Mines & Smelters, although he has not, heretofore, been an official of the new concern, though the largest stockholder. The company is shipping concentrate to the Tooele plant of the International Smelting & Refining Co. and expects to output 1000 tons per month. The Lake Copper Co., which last winter was acclaimed the greatest recent copper development in the Michigan copper country, and sold up to $90 per share on the Boston Exchange, now requires further financing, 13,450 shares of treasury stock having been underwritten at $35 per share. Stockholders may have rights at this figure on the basis of one share for each seven shares held. The $444,000 which will be available by the sale of this stock is expected to finance the company for a year and a half. The El Rayo Mines Co., which has recently been paying dividends, has announced that further dividends will be deferred until after January 11, 1911, when the time for the exchange of El Rayo and Dolores into the enlarged Mines Company of America will expire. Both the Mines Company of America and the Dolores are making similar postponement of dividends, the current earnings being applied to the purchase of the La Dura in Sonora, Mexico. This is the first additional property to be acquired by this merger, formed some months ago as a developing and holding company. On the exchange basis more than 90% of both Dolores and El Rayo has been exchanged for the new Mines Company of America. The deal for the La Dura involves a cash payment of about $400,000.

L. Vogelstein & Co., who represent Aron Hirsch & Sohn in this country, have secured the contract for the refining and selling of the output of the Mt. Lyell, which is one of the largest producing coppers of Australia. These ores have heretofore been handled by the American Smelting & Refining Co. at its Baltimore plant. The Hirsch-Vogelstein combination is making a strong bid for the handling of all the Australian output. An electrolytic refinery has been erected by these interests, acting jointly with the Mount Morgan Gold Mining Co., the refinery being known as the Electrolitic Smelting & Refining Company of Australia, Ltd. This plant is now being enlarged to take care of the Mt. Lyell output, and the refined copper will be sold by the Hirsch-Vogelstein combination.

General Mining News

ALASKA

The Alaska Mexican Gold Mining Co. reports for the month ended October 19, as follows: mill, 120 stamps, run 30 days 17 hr. 54 min.; water-power, 2 days 17 hr. 54 min.; steam-power, 28 days 4 hr. 20 min; tons ore crushed, 19,772; tons concentrate saved, 365; estimated value of free gold, $35,431.20; estimated value of concentrate, $37,295.92; less amount due Alaska United G. M. Co., $1912.08; total production, $70,815.04; realizable value, $68,270.73; operating expense, $29,403.07; net operating profit, $38,867.66; construction expense, $10,073.62; yield per ton $3.58; stock of broken ore increased 2332 tons; development work, 254 ft. in ore, 316 ft. in waste; assays run from $1.44 to $2.96. ——The Alaska Treadwell Gold Mining Co. reports for the month ended October 15, as follows: 240-stamp mill, run 30 days 6 hr. 21 min; water-power, 3 days 14 hr. 37 min.; steam-power, 26 days 15 hr. 44 min; 300-stamp mill, water-power, run 22 days 4 min.; tons of ore crushed, 240-mill, 35,952; 300-mill, 38,248; total, 74,200; concentrate saved, 240-mill, 625 tons; 300-mill, 610 tons; total, 1235 tons; estimated value free gold, $115,400.11; estimated value concentrate, $65,720.90; total production, $181,121.01; realizable value, $172,557.01; operating expenses, $88,566.27; net operating profit, $83,990.74; construction expenses, $28,235.33; yield per ton of ore crushed, $2.44; stock of broken ore increased 17,077 tons; development in ore 153 ft., in waste 318 ft.; assay value, $2.18 to $3.11.

ARIZONA

GILA COUNTY

(Special Correspondence.)—Hayward, Holden, and Smith, mining engineers of Denver, Colorado, have completed an examination of the Inspiration mine for Hayden, Stone & Co., of Boston. One of them says the mine can easily supply a concentrator with a capacity of 5000 tons per day, but that the construction of such a mill will probably not be commenced until next spring, as much valuable

Miami Portion of Globe District.

information can be obtained from the working of the Miami Copper Co.'s plant, which begins operation about Jan. 1 next.——The vein opened last week on the eighth level of the Superior & Boston mine has proved to be the so-called Iron Ledge fault and not the Great Eastern vein. The Iron Ledge crosses the Great Eastern diagonally. The drifts following this fault have shown much iron and some copper stain. These drifts are 30 and 50 ft. long, respectively; the longer one running northward is expected to strike the Great Eastern vein in a short distance.——The winze sunk on the Old Dominion vein at the Arizona-Michigan property is 106 ft. deep and a cross-cut has been driven from the winze to the vein at that depth. This cross-cut is 25 ft. long and has penetrated the vein 8 ft., but has found only crushed material stained with hematite. ——The Superior & Globe Copper Co. has started a second diamond-drill hole horizontally into the country rock from the 650-ft. level. This hole is 60 ft. long and is in diabase. It is estimated that it will cut a vein 250 ft. from its starting point. The hole driven downward, to tap the Yuma vein at 1260 ft. from the surface, is 330 ft. deep. H. V. Snell is superintendent.——The Summit Copper Co. employs 48 men in development work, ten miles west of Miami, where operations have lately exposed much high-grade copper ore.

Miami, October 29.

MOHAVE COUNTY

(Special Correspondence.)—There is considerable activity in the San Francisco district, near Kingman, where the Tom Reed and Gold Road mines are producing steadily. Several engineers and prospective investors have been in the district recently. At the Frisco mine, in Union pass, a large body of ore is reported to be developed, and the 100-ton mill is nearing completion rapidly. Two recent discoveries of good-grade gold ore are reported from Secret pass, three miles to the south. Five miles farther south the Ruth mine is being reopened and preparations are going forward for the construction of a mill. The deepest workings here are a 115-ft. shaft on the Ruth claim and a 216-ft. shaft on the Rattan. A new working shaft has been started on the foot-wall side of the vein on the Ruth, dipping at an angle of 60°. This is 35 ft. deep and in a good grade of gold ore at the bottom. A head-frame and hoist, good for a depth of 500 ft., will be erected. ——Engineers recently examined a tungsten property in the Aquarius mountains, Mohave county, about 12 miles by hard trail from Owens on the Big Sandy river. The property has not been developed to any great depth, but adits have opened several small veins, in which wolframite occurs in bands in a quartz vein. Up to the present work has consisted in mining the high-grade mineral and 8 or 10 tons have been shipped. Development consists of many open-cuts and small adits, the longest being 175 ft. The Planet mine, near Bill Williams fork, has been closed recently by the General Development Co. This company has been operating the mine for more than a year, during which the workings have been extended to a depth of 600 ft. Several drill-holes have also been put down to explore the sulphide zone. It is reported that low-grade sulphides were developed, but accurate information is not obtainable. There is some activity on the California side of the Colorado river from the Copper Basin district, north of Monument peak, south to Riverside mountains. Several properties have been reopened and prospecting is in progress at many points. The Calzona Mines Co. and the Steece Copper Co. have resumed operations at their properties 17 miles southwest of Parker. Several carloads of machinery and supplies have been shipped in within the last few weeks.

Kingman, October 28.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—N. Glavinich was killed in the South Eureka mine on the night of October 29, while repairing the shaft track below the 2500-ft. station. He was struck by a falling rock, and fell to the 2700-ft. point where a bulkhead had been placed. Extensive shaft repairs are in progress at the South Eureka mine.——The Chichizola Estate Co. of Amador City attached the Wildman Mahoney mines at Sutter Creek last fall, to secure the payment of a debt of the California Con. Mines Co., owning these mines. The property is now advertised by the sheriff, who will sell it to the highest bidder on November 12, to satisfy the judgment in favor of the plaintiff. The sheriff also advertises the sale of the Consolidated Keystone properties, on November 19, to satisfy a judgment in favor of D. J. Cambie, who attached the property in the interest of himself and others for wages due. The court has appointed John H. Isham receiver for all the property of the California Con. Mines

Co., which includes the Keystone group at Amador City and the Wildman Mahoney group at Sutter Creek.

Jackson, October 28.

IMPERIAL COUNTY

The long-idle mines at Hedges, six miles northeast of Ogilby, on the Southern Pacific, are being rejuvenated. About December 1, crushing in the 100-stamp mill will begin, but 50 stamps being dropped at first. A new 6-in. pipe line is being laid from the pump station on the Colorado river, and the old water line will be utilized as an oil line between the railroad and the mines. It is expected gradually to get the entire 140 stamps in operation, and perhaps to increase the size of the plant.

KERN COUNTY

The discovery of a new vein of high-grade ore at the Butte mine at Randsburg has resulted in renewed activity on Butte hill. The vein has been traced for nearly 1500 ft. into the adjoining King Solomon ground. Six shafts and five sets of lessees are opening ore at various points along the strike. At the Butte mine, the superintendent, Mr. Fayhe, is sinking on the ore, and the shaft has passed 50 ft. and still shows the vein, 12 in. wide, and worth about $100 per ton. A recent cloudburst is responsible for the discovery. In walking along the road after the downpour, Mr. Fayhe picked up pieces of ore showing gold.——Easterly from the Butte shaft, Watchman Bros. & Cagle have reached a depth of 100 ft. and are taking out good ore. Farther along two shafts are being worked on the Halford lease. Three men are being employed on the adjoining Zackley lease and some good ore is being taken out.

TUOLUMNE COUNTY

(Special Correspondence.)—J. L. Witney of Los Angeles has completed an examination of the Dutch and Sweeney mines, on the Mother Lode, near Jamestown. It is probable that this property will be reopened. The shaft is 1730 ft. deep and about 30,000 ft. of levels have been driven. On the 1200-ft. level ore of milling grade shows a width of from 50 to 75 ft.——At the Harvard mine, north of the Dutch and Sweeney, a discovery of rich gold ore on the 900-ft. level is reported. This property is developed down to the 1100-ft. level. A 60-stamp mill is in operation.——The Water Lily Gravel & Leasing Co., composed chiefly of San Francisco people, has begun operations on a gravel property on the Stanislaus river, three miles below Robinson's Ferry. The deposit is in an old river bed and is reached at a depth of 40 ft. A two-compartment shaft, 4 by 8 ft., will be sunk and drifts run to the gravel.

Jamestown, October 28.

The United Mines Corporation of Cleveland, Ohio, is developing a group of mines near the town of Tuolumne. This group includes the Eureka, Deadhorse, Lady Washington, Grizzly, and New Albany. These mines are all on the East Lode and several of them have been worked extensively, particularly the old Eureka, Deadhorse, and Grizzly. Hardinge conical tube-mills are in use in the metallurgical plant.——It is reported that a large pocket has been discovered in the Tarantula mine, north of the Rawhide.——J. C. Huston has resumed river channel mining at Moffit bridge, near Chinese, and will take advantage of the low water.——In the Longfellow mine, at Big Oak Flat, driving and cross-cutting are in progress at the 800-ft. level. The shaft will be sunk to the depth of 1000 ft.——The Karnac Mining Co. has bought the 10-stamp mill at the Horseshoe mine and hauled it to its property near Rawhide.——It is said that Los Angeles men have bonded the Wickam mine, near the Rawhide.

COLORADO

GILPIN COUNTY

John W. Dean, Vandyke Moore, and Chris Grendmaier, miners employed in the Frontenac mine at Central City, were instantly killed by the premature explosion of a blast in a cross-cut on the 600-ft. level, on October 22. It is thought that in loading a series of holes a detonater in some manner was pushed to the side of the stick of nitro-powder in which it had been inserted, and was forced against the rock at the side of a drill-hole when the charge was being tamped. The blast caused the explosion of 60 additional sticks of 60% powder lying on a shoveling sheet at the face of the cross-cut. Another theory was that something caused the box of detonators to explode, which exploded the powder on the floor, the blast exploding later. These theories were advanced for the reason that two distinct explosions were heard.——The Federal mine in Russell gulch has a face of ore 4 ft. wide, which carries gold and copper.

OURAY COUNTY

The Anderson-Halter Mines Co. has bought the Micky Breen mines and mill and the Grizzly Bear mines near Ouray. The properties have been idle for some time.

SAN MIGUEL COUNTY

Lafe Crandall, a miner, while at work in the Smuggler-Union mine, near Telluride, drilled into a 'missed hole' on October 27 and was seriously though not fatally injured.——The Moorehead Mining & Milling Co. has filed a suit against the Liberty Bell Mining Co. for damages claimed for alleged trespass. It is another apex case.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—The Marsh Mining Co., operating in the Coeur d'Alene, will begin shipping about the middle of November. Driving on the 500-ft. level is under way. The vein was cut recently by a cross-cut from the 200-ft. level from the main shaft. The vein was 5 ft. in width, of which more than 50% is of clean shipping ore.——E. P. Spalding, president and manager of the Monarch Mining Co., operating in the Coeur d'Alene, says that the new 200-ton mill will be ready for operation December 15. Meantime the old 75-ton mill is in operation on the ore taken out in development. Shipments are at the rate of 6 to 8 cars of concentrate monthly.——Ground has been broken at Wallace on the site of the new 400-ton concentrator for the Hercules Mining Co. The company has been operating the old Tiger-Poorman mill at Burke. The mill will be modern and will probably take four months for construction.

Spokane, October 24.

MICHIGAN

ONTONAGON COUNTY

Adventure's vertical shaft has reached rich copper ground in No. 1 lode. The shaft is not placed exactly parallel with the strike of the lode. The vertical distance through the copper-bearing part of the lode, as exposed in the shaft, is about 16 ft., according to the latest developments. Assuming an incline of 45 degrees for the lode, this indicates that the rich part of the lode, when the shaft perforates it, has a thickness of 12 ft., measuring at right angles to the incline. People from all parts of Ontonagon county have visited the shaft and carried away specimens, and the general sentiment is that a highly satisfactory showing has been made. Sinking is still in progress. It will be necessary to get 15 or 20 ft. below the lode before cutting a station, if one should be established at this time. It has not been fully determined that a station will be cut at this depth during the present year.

MISSOURI

JASPER COUNTY

(Special Correspondence.)—Among the new producers in the Joplin district is the Jim D. mine, at Webb City, which has been making regular shipments of 30 tons weekly for some time past. The mill is on the M. & S. land at Carterville where a deposit has been opened at 140 ft. in boulder ground. It is neither typical sheet ground nor soft ground. The mill is a new one of 150 tons capacity.——The Mercedes Mining Co. has been developing a deeper run of ore on the Center Creek land, taking a large stope from the 130-ft. level to 190 ft. The company is making

an effort to mine the lower ground without running new drifts. There are two shafts; one operates on the upper level and the second has been put down to the greater depth. This mine has been producing steadily for years. ——On the same land the Comet company has begun operations with the new 200-ton mill on land which was extensively mined in the early days, when the operations were shallow—from the surface to 130 ft. Lately operations have been deepened to 190 ft. where drill-holes showed better ore. The Comet company has opened the Rattler mine which operated here previously.——The Maggie G. mine at Thoms station is being reopened and unwatered after a long idle period.——A new shaft has been sunk north of the mill which will enter the ore at 190 ft. A long tramway has been built to connect the new shaft with the mill. The blende is high grade and is found in large pockets. There is only a small amount of galena.——In the vicinity the old Katherine mine has run drifts into rich ore in two directions. This company is one of the oldest in this part of the field. Stopes have been taken up at different times until the drifts are very high and heavily timbered. ——To the west of Joplin, in the recently developed disseminated-ore field, several companies are working. Some new mills have recently been added to the camp, among them the Muskingum, a modern plant of 300 tons capacity. Some new features have been added to this mill, one being the greater attention given to the slime. The mill con-

A Joplin Prospect.

tains six concentrating tables of different types. Another unique feature is the ventilating system of the mine, there being large suction fans attached to drill-holes sunk to draw out the foul air, the pure air flowing down the main shaft. When the drift is extended too far beyond the drill-hole for perfect ventilation, another drill-hole is sunk to the face.——The Hackett mill is progressing slowly, owing to the elaborate plans for its equipment. The main buildings have been completed and there remain only the placing of the machinery and its adjustment.——In the same field the Kittie Mack has recently completed a 225-ton plant to replace one destroyed by fire, and the company has resumed operation after months of idleness. The plant is modern throughout, and more attention is given to the saving of fine than previously. The ground is well opened at the 180-ft. level and carries an 18-ft. face of disseminated ore.——A new prospect has been opened on the Sampson land near the Kittie Mack lease which is unique for that part of the field, as it is in soft ground instead of the prevailing disseminated ground. The ore occurs above the disseminated level and a shaft has reached that depth. It also carries a larger per cent of ore.

Joplin, October 27.

MONTANA

SILVER BOW COUNTY

Four miners in the Leonard mine at Butte were instantly killed by a premature blast on Tuesday morning last. They were Finns.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The last shipment from the Socorro mines consisted of 11 bars of gold and silver bullion, produced from only a part of the precipitate on hand. An increased tonnage is being crushed. Work is progressing in sinking the 3-compartment vertical shaft.——At the Ernestine the mill is running full time, crushing 100 tons per day; 36 sacks of high-grade concentrate was produced from 620 tons crushed. The precipitate accumulated since the recent pipe-line installation has not been melted.——At the Deadwood mines rapid progress has been made in the erection of the mill. The main building, started a month ago, is under cover. The reinforced-concrete foundations for the mortars are completed, the engine foundation is being laid, and all other work is keeping pace. Cheap power and filter operation have received exhaustive investigation by the owners of this property, and it is believed the innovations in these departments will prove to be a big stride toward low milling costs.——The Mogollon Gold & Copper Co. is grading for a sawmill which will be installed to square timbers for the main shaft on the Cooney mine, which the management reports will be unwatered and retimbered. In the meantime the main adit is being advanced on the East vein, which is showing native copper at a depth of 600 ft. below the apex of the hill. Development continues on the Bloomer Girl, Fluoride, the Little Charlie groups, and the Malachite mine, all this work furnishing a milling grade of ore.——The Gold Dust Mines Co. is developing its property situated on a vein lying south of the Last Chance. Gold predominates in the ore thus far developed.

Mogollon, October 28.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The Goldfield Mining & Ore Reduction Co., for which M. Arnold is manager, has had the Golconda claim under lease from the Goldfield Con., and is negotiating for an extension of the lease. This lessee has sunk four shafts, one to a depth of 428 ft. Several hundred feet of cross-cutting has been done, and if lease is renewed exploration will continue in the search for ore. The company has expended $115,000 in development and equipment in Goldfield.——The Goldfield Annex Mining Co., composed of Philadelphia operators, having a lease on the Palo Verde claim of the Jumbo Extension group, has sunk a 1065-ft. shaft on that property, 400 ft. east of the Clermont shaft of the Goldfield Con. group. The shaft has three compartments and is timbered. Surface equipment consists of a 75-hp. electric hoist and an 8-drill air-compressor. The lateral work from the shaft amounts to 2500 ft. on all levels. They found some ore on the 800-ft. level, some of which was marketed. A raise is being cut from the 1000-ft. level to the vein, on its dip, that was opened on the 800. Alex T. Baugher, one of the stockholders, who has direction of operations, states that the company's lease runs one more year.——Donald Ferguson, while recently in the East, effected a consolidation of various properties lying east of the original part of Goldfield under the name of the Pittsburg-Nevada Mining Co., for which he is the manager. The groups merged include the Red Top, Dixie, Mayflower, and Frances. There are now several shafts, including one 400 ft. deep. Work on the Mayflower opened a 53-ft. vein at a depth of 400 ft., 29 ft. of which is quartz containing excellent value in gold and silver. New equipment is to be installed and development is to begin soon.——The Combination Fraction, controlled by George Wingfield, and managed by C. D. Wilkinson, has a 750-ft. shaft, from which seven levels have been opened. Work is progressing on six of these, producing 60 to 70 tons of ore per day, which runs $20 to $30 per ton, and is treated at the old Nevada-Goldfield plant which is under lease to the Fraction company.——Two sets of lessees at work on the Booth are not yet shipping ore; four sets are at work on the Sandstorm and Kendall,

from which small shipments are being made. The Goldfield-Daisy Syndicate, owner of the Daisy at Diamondfield, has let one lease from which some ore is being shipped. Lessees are at work on the Blue Bowl, but are not shipping as yet.

Goldfield, October 27.

EUREKA COUNTY

(Special Correspondence.)—The Buckhorn mine, one of George Wingfield's Nevada properties, situated 35 miles south of Palisade, and 30 miles from Beowawe, produces gold and silver ore, which it is believed can be successfully cyanided. It is undergoing thorough development with F. J. Seibert in charge. The erection of a crushing and cyanidation plant has been deferred till next spring. It is thought the Palisade & Eureka railroad will be rebuilt. This line, or a large part of it, was destroyed by high water last May.

Eureka, October 28.

HUMBOLDT COUNTY

(Special Correspondence.)—The Ohio mine, situated on Rebel creek, 54 miles north of Winnemucca, the sale of which to Milwaukee men was negotiated by Donald Ferguson of Goldfield, is to be put in order this winter and a mill is to be erected next spring. Mr. Ferguson states that mill ore of the value of $100,000 is on the dump, and that a large tonnage of similar ore is blocked out in the mine. The ore carries gold and silver which will probably be recovered by concentration and cyanidation. Mr. Ferguson is to have the management of the property.

Winnemucca, October 26.

NYE COUNTY

(Special Correspondence.)—The Goldfield-Bluebell Mining Co., operating the old Stokes mine and a 30-stamp mill at Berlin, has been shipping concentrate and gold bullion with some regularity for two years. The ore is gold-bearing quartz, the recovery being made on amalgamating plates and on concentrating tables. The ore runs about $8 per ton. The vein has a width of 18 in. to 10 ft., and is opened by an 800-ft. incline shaft. The mill, hoist, and other machinery are operated by steam power, wood being used as fuel. D. S. Johnson is manager. Berlin is 65 miles south of Austin.

Berlin, October 25.

(Special Correspondence.)—The Rescue and North Star properties, situated close to the Belmont at Tonopah, are being reopened by Lockett and others, with A. J. Canavan in charge of the work.

Tonopah, October 28.

STOREY COUNTY

On October 28 hydraulic elevator No. 2 in the C. & C. shaft at Virginia City was lowered into the sump below the 2650-ft. station. This is the greatest depth to which the ejector has ever been worked. It lifts the water to the tank on the 2150-ft. level, where the electric pump sends it to the Sutro tunnel level.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—The Le Roi mine, which only a few years ago was the leading gold-copper mine of this camp, and which has produced millions of dollars worth of ore, is now offered for sale by the liquidator, A. J. McMillan, of Rossland. There is a large quantity of low-grade ore still in the mine, which should average about $10 per ton in gold, silver, and copper. When it is considered that the Boundary mining companies are taking out $3 ore, it will be seen that there are possibilities for the Le Roi. The engineers state that it would take several hundred thousand dollars to prospect for ore that is of a better grade than that now blocked out. It is reported that the Great Northern railroad may interest itself in the property, benefiting by the long haul to Grand Forks and the business the operation of the mine would create. It is also thought that either the Consolidated, or Le Roi No. 2, Ltd., of Rossland, could work this property to advantage.——Work on the Blue Bird mine is resulting in important ore discoveries. At 45 ft. depth in the main shaft 30 in. of solid galena has been found. A shaft-house is being built and the working force augmented. ——The September report of the Le Roi No. 2, Ltd., shows receipts from Trail smelter amounting to $44,603, covering 2364 tons ore and 82 tons concentrate. Expenditure for development, ore production, and mill operations was $19,350. New work on the Surprise property consists of 19-ft. drift, 24-ft. winze. The 1300-ft. level was advanced 127 ft., of which 30 ft. assayed 34 gr. gold and 1% copper.

Rossland, October 25.

(Special Correspondence.)—Ore shipments from the Rawhide mine of the New Dominion Copper Co. to the Greenwood smelter have increased from 1100 to 3000 tons per week in the past month. The net earnings of the British Columbia Copper Co. for September amounted to $27,600. Copper was produced at a cost of 8.3 cents, a slight increase over August, when this cost was 7.7 after making the usual deductions for gold and silver. The three furnaces are in operation.——The Tip Top mine, near Greenwood, is again in operation, five men being employed. Work has also been resumed at the Bay property. It is the intention to make shipments over the snow roads this winter. At the Napoleon mine the B. C. Copper Co. has 60 teams and scrapers stripping.——The ore shipments from the Boundary district for the week ended October 22 were 28,445 tons.

Phoenix, October 26.

MEXICO

OAXACA

(Special Correspondence.)—Among the resident mining men it is well known that there is more activity in mining matters than is supposed by the public. This camp passed through a boom three to five years ago, when money was plentiful and mining claims were held at ridiculously high figures. As is usual in such times, there was little work of merit being done. Wild-catting was the order of things and fortunes changed hands in short time. At present there is more ore being taken out than in Oaxaca's palmy days. The workers of early years have left their marks, and their work can be traced in places, the most interesting probably being the wooden stamps and wheel-transmission of the early English, some of which are still in fair condition. At present the San Juan, Purisima, Esperanza, Sanford, Veronica, Rosario, Escuadra, and a number of other properties in Taviche district are shipping ore. In the Sierra Juarez district, aside from the Natividad mines, possibly the best known in the State, the Colonial Mines Co., of Boston, the Old Mexico Mining Co., of New York, the various properties of Maurice Clark, and others, are being operated with good results. In the Totolapam districts the La Leona mine and mill, the Soledad Mining Co., Harold Sturgis, La Victoria y Tapada mines, J. L. T. Hall, and W. E. McEwen are the best known, most of which are in bonanza and are either shipping or treating the ores in local mills. In the gold belt of the Parian, Perez, and Penoles districts several mills are running, another is being erected for Sr. Montroy at Perez, and, while this is the least active of all the districts, enough returns are being received to make a good showing.——In the San José and Ejutla districts, the San Martin, operated by a Canadian company, is working full time in development; the Tezuitlan Copper Co.'s property; Los Ocotes, known to have more value in sight than any other mines in the State, and various others, are operating extensively. The La Alianza, under the management of F. M. Woods, is in bonanza and shipping ore.

Oaxaca, October 25.

CHIHUAHUA

The Palmilla mine is to put three centrifugal pumps, each of 1200 gal. capacity, on the eighth level. The pumps can be operated either singly or together as desired. The column pipe is 13 in. diameter.——It is reported that in the Guadalupe mine at Inde a body of high-grade ore has been discovered.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. M. Rolker is in San Francisco.

Francis Drake has gone to London.

C. K. Leith has returned from Brazil.

W. S. Noyes was at Oroville this week.

E. A. Montgomery has gone to Guanajuato, Mexico.

A. D. Miles has been visiting San Francisco and other Western points.

R. B. Lamb has opened offices in the Traders Bank building, Toronto, Canada.

Charles D. Kaeding has gone to Nicaragua. He will return about February 1.

G. H. Cady is at Urbana, Illinois, this winter with the State Geological Survey.

Norman C. Stines has been in Berlin and London and will be in New York next week.

John Gross, of Draper & Gross, has gone to Sonora, Mexico, on professional business.

Jesse J. MacDonald has gone to Bluff, Utah. He will return to Los Angeles December 1.

H. H. Webb is at Porcupine, Ontario, managing the Rea mines for the Consolidated Gold Fields of S. A., Limited.

Mark R. Lamb left on October 25 for an extended commercial journey in South America for Allis-Chalmers Company.

N. Y. Truschikoff, manager of the Blagodatny mines and smelter at Ekaterinburg, Russia, was in San Francisco this week.

Moaton Webber has returned to New York from North Carolina, where he has been examining mines for New York clients.

Rush M. Hess has left the service of Cia. de Real del Monte y Pachuca to become engineer for the South American Mines Co., Guayaquil, Ecuador.

O. F. Westlund, formerly manager for the A. S. & R. Co. of the Aguas Calientes smelter, is general manager in Mexico for the Mines Management Co. of New York. His office is at Num. 48, Avenida 16 de Septembre, Mexico City.

G. E. Webber, who has been associated with H. Eckstein & Co. for seventeen years, has resigned as general manager of the Rand Mines, Ltd. He will remain at Johannesburg until April, after which his American friends hope to see him at home.

OCTOBER COPPER REVIEW.

By M. E. Appelbaum*

During the month of October the price of copper rose from 12½c. delivered thirty days, to 12⅞c. delivered thirty days, and the buying for both domestic and export trade assumed large proportions. In fact, more copper was sold during the month of October than in any month during the last half year. The advance was principally due to the more favorable European statistics and to the large decrease in the surplus reported by the Copper Producers Association. In that report the production for the first time showed the effect of the curtailment policy, and the statistics for the month of October are expected to show a still further falling off. I estimate deliveries for the month of October to be about 67,000,000 lb. each for export and domestic trade, against a production of about 112,000,000 lb., thus indicating a decrease of about 22,000,000 lb. The key to the metal situation lies with the railroads, which, it is expected, will have to order large equipment. If these orders materialize and the curtailment policy continues, it is confidently expected that the metal will continue to advance gradually, and it will not be surprising before long to see a 13½c. level established.

*President the New York Metal Selling Company.

Market Reports

CURRENT PRICES FOR ORES AND MINERALS

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked*.

	Min.	Max.
Antimony ore, 50%, per ton	*$20.00	$25.00
Arsenic, white, refined, per lb	0.03	0.03½
Arsenic, red, refined, per lb	0.08	0.09
Asbestos, according to length and quality of fibre, per ton	100.00	350.00
Asbestos, lower grades, per ton	10.00	100.00
Asphaltum, refined, per ton	15.00	20.00
Barium carbonate, precipitated, per ton	42.50	45.00
Barium chloride, commercial, per ton	42.50	47.50
Barium sulphate (barytes), prepared, ton	20.00	30.00
Bismuth ore, 10% upward, per ton	*75.00	upward
Chrome ore, according to quality, per ton	10.00	15.00
China clay, per ton	15.00	20.00
Cobalt metal, refined, f.o.b. London, per lb	2.50	
Coke, foundry, per 2240 lb	15.00	17.50
Diamonds:		
Borts, according to size and quality, per carat	2.00	15.00
Carbons, according to size and quality, per carat	75.00	100.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Bauxite, per M	175.00	200.00
Magnesite, per M	200.00	250.00
Silica, per M	47.50	
Flint pebbles for tube-mills, per 2240 lb	15.00	25.00
Fluorspar, per ton	10.00	15.00
Fullers earth, according to quality, per ton	20.00	30.00
Gilsonite, per ton	32.50	45.00
Graphite:		
Amorphous, per lb	0.01	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	7.50	10.00
Infusorial earth, per ton	10.00	15.00
Magnesite, crude, per ton	7.50	10.00
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	45.00	125.00
Mica, according to size and quality, per lb	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per lb	0.02½	0.03½
Platinum, native, crude, per oz	*20.00	25.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 70%, per ton	*400.00	450.00
Tungsten ore, 65%, per ton	*475.00	520.00
Vanadium ore, 15%, per ton	*100.00	125.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00
Zinc oxide, per 100 lb	7.50	8.50

CURRENT PRICES FOR CHEMICALS

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

Zinc shavings, 800 fine, bbl., 100 lb	10.75	11.75
Zinc sheet, No. 9—18 by 84, drum, 100 lb	9.75	10.75

Tin shipments from the Straits settlements for the first half of October, according to L. Vogelstein & Co., were reported by cable as approximately 2000 tons, about 4300 tons being estimated for the entire month. As October is not a 'banca sale' month, and assuming that United States deliveries will again be good, a considerable shrinkage in the visible supply is indicated. Even so, if the present market is maintained values will appear high. There is, however, no relation between stocks and prices. During the first 10 months of this year the visible supply will have decreased between 5000 and 6000 tons; surplus stocks are closely held in strong hands and demand continues equal to if not in excess of supply. Under such circumstances control of stocks means control of the market and we still hold that "in the absence of forced liquidation we see no reason to apprehend lower prices and of forced liquidation there is no prospect." (See our letter of August 13). The Syndicate's operations naturally attract tin to London. Yet there was in store and to arrive at that port October 1. only 1000 tons more than at the same time a year ago.

EDITORIAL

DECREASES in visible stocks of copper, tin, and spelter are all reported. This can only mean better prices, whether it be due to increased consumption or curtailment of production.

COLORADO is interested in the announcement that a new railway is to be built from the main line of the Denver & Rio Grande near Newcastle, north into Rio Blanco county and ultimately, it is hoped, to Utah. The projected railroad will open important coal and oilfields. Gilsonite and carnotite deposits also occur in the territory to be traversed.

NOME suffered November 3 from a disastrous flood due to heavy surf driven over the sand spit and through the lower part of the city. No one was killed, but there were heavy losses in provisions and other property, ruined or carried away to sea. It is suggested that the tidal wave was caused by submarine disturbances connected with the recent volcanic activity of Mount Bogoslof and Mount Shishaldin.

ZINC-SMELTING conditions have changed radically in the last year. Several months ago we presented a careful analysis of the situation by Mr. R. G. Hall, manager of the United Zinc & Chemical Company, indicating that a shortage in spelter was to be expected this winter. The pinch is already slightly felt, and with increasing cold weather and resulting demand on the Kansas gasfields, may be expected to be intensified.

SUBSCRIBERS and others frequently write to us, but neglect to sign their names, or else use an assumed signature. This is probably due to a misunderstanding. It is impossible to pay any attention to letters unless the genuine name of the sender is attached. This is not necessarily for publication, indeed there is rarely any objection to the use of a pen name for that purpose when it is preferred, but the Editor must have some evidence of the good faith of the correspondent. Aside from that, it is often simpler to answer by letter than through the columns of the paper. This is impossible unless the correct name and address be given.

OIL MEN from all parts of California are expected to meet at Bakersfield today and attempt to get together in their requests for modification of recent rulings of the Land Office. The major difficulty lies in the requirement that discovery shall be made prior to location. It could ordinarily be met by prompt re-location after discovery. In the areas covered by withdrawals this is now impossible,

and in effect the ruling, however well founded, operates to defeat the law that was intended to permit patents to issue to those who had located lands prior to withdrawal and have proceeded in good faith to develop them. The injustice of this is so apparent that it can hardly be doubted that some means will be found by the Department to modify the rules so as to carry out the intent of the law.

EARLY returns from the election indicate large Democratic gains. Election of Mr. Woodrow Wilson to be Governor of New Jersey and re-election of Mr. Judson Harmon in Ohio are especially noteworthy and are causes for congratulation. In New York, Mr. John A. Dix has been elected, greatly to the delight of Wall Street, which, as our correspondent states, was a unit on 'anything to beat Roosevelt.' It is interesting to recall that until Mr. Roosevelt entered the campaign few had any hopes of electing a Republican successor to Mr. C. E. Hughes as Governor. In California, Kansas, and other States the progressive Republicans won notable victories, though in Indiana and elsewhere they were defeated. On the whole, the results are not clearly decisive. The new issues have not yet brought out new leaders with nation-wide followings.

THE RECLAMATION SERVICE is engaged in construction work of first importance. It has not hesitated to attempt doing new things or adopting new methods. To engineers one of the most interesting phases of its work has been the large amount of construction carried out on force account and the small amount of contract work done. The showing presented on another page is greatly to the advantage of the force-account system. The same result followed from its introduction on the Los Angeles aqueduct work and must follow wherever conditions permit honest and capable supervision. Contractors naturally, and properly, estimate to cover the maximum risk, and there must be contractors' profits or the business would not continue. Capable assistants and foremen can be found to work directly under the engineers as well as under a contractor, and if such men are not employed something is wrong. Incidentally it may be remarked that the substitution of force account for contract work lies at the bottom of some of the criticism of the Reclamation Service.

THE PONDEROSA copper mine in the Collahuasi district of Chile is one that is well known for the great body of high-grade ore present. When the property was purchased by the Ponderosa Mining Co., Ltd., from the Chilean company that opened the mine, it was estimated that 100,000 tons of ore containing 25 per cent copper and 12 ounces silver per ton was developed. The new company started under apparently good auspices and in July 1909 paid a five per cent dividend, amounting to £26,458. Soon, however, there were rumors of trouble, though details were not made public. The manager and several members of the Board resigned and a new administration came in charge. It promptly became clear that the payment of the dividend had not been warranted. The mine is situated at high altitude and the engineers evidently have great difficulties to overcome. At the same time, the cost of production, and the fact that there was a deficit rather than profit after 25,782 tons had been sold, are surprising in view of the value of the ore. That shipped in 1909 averaged 22 per cent copper and 6½ ounces silver and brought £181,211. The cost of mining is stated to have been £188,253, including £40,489 for transportation, but not including £7487 for development, £6069 allowed for depreciation, and £16,945 for management in London and at the mine. In the absence of complete data it is difficult to determine what has been included under the item of management, and why the cost should have been so high. It would appear that there was either poor work or poor bookkeeping.

Mapping South America

Maps are among the important but little considered adjuncts of civilization. They are essential to any complete development of a territory. All the great nations maintain bureaus for making surveys and publishing maps. Most of them support geological surveys whose special function it is to make maps showing the distribution of different formations. At first each country established its own scale and each geologist used any color scheme that met his fancy. Gradually a measure of uniformity has been brought about, largely through the activity of the International Geological Congress. This has many points of practical advantage. An engineer may be wholly ignorant of Russian or Japanese and yet be able to read the excellent geological maps published in those countries. This is possible because according to the international scheme, Carboniferous rocks are represented by various shades of blue, Cretaceous by green, Tertiary by yellow, and a different color is assigned to each system. Some years ago arrangements were made by the leading European Governments to co-operate in producing a great map of Europe on a uniform scale of one to one million, and many sheets of this have now been issued. Later the United States, Canada, and Mexico became parties to the agreement, and the preparation of a world map is now in progress. Mr. Bailey Willis, well known for his excellent work in connection with the United States Geological Survey and for his monumental 'Research in China,' has now enlisted the support of the leading South American nations. New and extensive surveys are to be undertaken in Argentina, Chile, Brazil, and Peru, and doubtless later in other countries. Mr. Willis has been invited to organize the work in Argentina by the Government of that country, and arrangements have been made at Washington for him to do so. Aside from the eminently practical results likely to ensue from the making of the surveys, this is a form of co-operation between the United States and South American republics that deserves hearty approval. The people of the two continents need more contact on the intellectual plane. Attention should not be devoted too narrowly toward promoting commercial relations. American geologists have rendered dis-

tinguished service in South America. Messrs. Ch. Hartt, O. A. Derby, and J. C. Branner in Brazil, I. C. White in that country and in Argentina, G. I. Adams in Peru, and many others, have contributed to the solution of the scientific and economic problems of our great South American neighbors. Mr. Willis is an especially fit man to carry on the work already begun and to extend and reorganize it as the need arises.

Railways and Politics

One of the beneficial results of the election held this week will doubtless be further decrease in the political activities of railways and other large corporations. There was a time when each great railway system in the United States supported a political bureau, and when, under the guise of local attorneys and tax commissioners, men were maintained in each community to look after the political interests of the road. Senators were made and unmade, Congressmen selected, and even local petty officials picked out on the basis of their faithfulness to the railway political machine. This is an open secret to anyone familiar with the practical workings of politics in almost any American State in the last twenty years. The evil effects of having political action controlled by special interests have been many. However honestly a railway manager may have desired only to protect the legitimate interests of his stockholders, he has been forced inevitably into alliance with all that was corrupt in our political system. The henchmen of the corporations have been the crooks and the grafters. It has been entirely too common in discussing the matter to heap condemnation on the railways without a fair consideration of the conditions that made activity in politics a practical necessity on the part of any manager who would do his duty by his stockholders. Not that the railway managers have been free from blame. They have been promoters as well as victims of the conditions, and on the whole have profited rather than lost. At the same time the blame rightly should rest in most cases on the community at large as well as on the conspicuous offenders. The situation in California may be used to illustrate what has been common elsewhere as well as on the Pacific Coast. Essentially it is a matter of taxes and the very human desire not to pay more, and if possible to escape with less, than one's neighbor. In California certain items of railway property have been assessed by a State board and others by local assessors. In the nature of the case a local official, familiar with the price of farm land and cattle, is not a competent judge of the value of railway property. The most expert would have difficulty enough since practically the largest value in any railway system is the intangible 'good will' or earning capacity incident to going concerns. The amount to be assessed therefore has been largely discretionary, and railways under these conditions have been forced to use every effort to secure election of assessors not unfriendly to them. Though more conspicuous, the problem is the same as in a county where both mining and agriculture are important. A farmer, elected to the position of assessor, is but human if he adjust matters so that the larger burden of taxes falls on mines; and, while we have high respect for men engaged in mining, we have no doubt that a miner as assessor would see more value in farm lands than would a farmer. The railways have labored under another disadvantage, in that they and other public service corporations have been open to attack through many dishonest bills introduced in legislatures with no other purpose than that those backing them should be bribed.

Wise managers have long realized the difficulties of the situation and many have made determined efforts to escape. The Colorado Fuel & Iron Company, long a most important factor in Colorado politics, at one time cut off all support from its political henchmen. Their years of activity had, however, built up an organization that lived on the spoils of corrupt politics, so that the company was forced to abandon for the time the effort toward righteousness. In California the activity of the Southern Pacific in politics has continued so long that it has been accepted as one of the fixed facts. Mr. Otto H. Kuhn in a recent interview has announced that the railroad will no longer support a political bureau, but will devote itself to its legitimate function of furnishing transportation. This announcement has been received with smiles of incredulity, since similar declarations have been made before. There need, however, be no doubt as to the desire of the owners of the system to stay out of politics, and in the primary and general elections the complete defeat of the old crowd indicates that the people are equally in favor of a new order of things. Fortunately there is reason for believing that a change is possible. Adoption of the constitutional amendment separating State from local taxation and changing the method of assessing corporation property, removes the main underlying difficulty—that of taxes. The railway and other large corporations will hereafter be taxed only by and for the State and being independent of local assessors, will have no interest in the election or defeat of particular candidates. In determining the amount to be paid as State taxes a simple mathematical rule is also substituted for the old discretionary authority. Railways, for example, are to pay four per cent of their gross receipts. Since this calculation can be made with equal certainty by a Republican or Democrat, an honest man or a grafter, the corporations no longer need look to the election of men to represent them in the State Board of Equalization. In many minor ways the condition has been improved. The way is open to better things. There will still be uninformed and dishonest men elected to the legislature and to other important positions, but in the main the underlying need for the railway to be in politics has disappeared and honest managers can hereafter devote themselves to their legitimate business if they wish. It is hopeless to attempt to make men honest by law, but each community owes it to all the individuals therein, corporate as well as others, to establish conditions under which honesty is possible.

Failure of the Yuba River Debris Barrier

By H. H. Wadsworth

*The structure on the Yuba river, California, commonly known as 'The Barrier' was one of those forming the system of works to restrain the movement of hydraulic mining débris down the Yuba into the Feather and Sacramento rivers. Some portions of this system are in operation, and others are in course of construction. The barrier failed on the night of Mareh 17 and 18, 1907, during the unprecedented flood that set new standards as to flood heights and stream flow, of the Saeramento river and all its tributaries, for engineers dealing with reelamation and flood eontrol problems.

Two steps of the dam were built, 6 and 8 ft., respectively, making a total of 14 ft. above what was the bed of the river when the first step was built. The first step was baeked by tailing on the oeurrenee of the first high water after its completion. Likewise, during the first flood following the completion of the second step, tailing banked up to its crest, and subsequent high waters carried large quantities of gravel over the dam, which caused considerable wear on the concrete surface. At the same time, the water, with its increased veloeity, due to its drop, eaused extensive scour at the toe. In 1906, it was decided not to raise the dam by an additional step, but to devote all the energy possible to excavating a spillway and construeting the side-wall, and to increasing the output of the quarry to a maximum for use in toe proteetion.

The Yuba river, the flow of whieh ranges from a minimum of about 400 see.-ft. in summer to a maximum of 125,000 sec.-ft. during extreme floods, maintained, during May and June and well on into July 1906, a flow of between 10,000 and 20,000 see.-ft. On aecount of the arrest of the passage of débris by the dam, which would eontinue to be effeetive, though in lessening degree, until the aeeumulation above it had been built up to a slope approximately parallel to the former slope of the river bed (about 19 ft. per mile at this point), the flowing water, thus relieved of its load above the dam, was able to piek up a new load below and scour out a channel downstream from the dam sufficient to prevent a water cushion from forming there, which would have served as some protection against further undermining aetion. Of more than 5000 tons of large rock placed at the toe of the barrier in 1905, comparatively little remained in sight by June of the next year, the seouring action having buried it in the gravel. The depth to whieh scouring extended was in some places as great as 12 ft. The undermining of the gravel from behind the plank bulkheading of the first row of piles extended baek under the dam irregularly, in some places as far as 4 ft. The surfaee of the river above the dam was 25 ft. above the lower part of the undermined face, but the fact that there was little or no evidence of seepage showed the density of this natural hydraulie fill. During the summer of 1906 this cavity was filled with rock placed by hand, and about 3500 tons of large rock was added to the rock apron, the theory on which this work was continued being that, as the high-water periods during whieh exeessive erosion oeeurred were separated by several months' time, it would be possible after eaeh flood to restore the settled roek fill to grade by the addition of new material, and that this proeess could be eontinued until the barrier had been raised to its final height. On reaching this point, the spillway, as designed, would have suffieient capacity to earry the entire flow of the river except during a very few days each year. How vital to the maintenance of the barrier the construetion of the spillway was reeognized to be, is shown by the following consideration. The nearest down-stream point whieh would limit positively the depth of scour above it was at Daguerre Point cut, 6 miles away, the sill of which was at El. 125. The conerete apron at the toe of the barrier was at El. 195. If, by reason of holding back the supply of gravel above, the scour continued below until a slope as flat as 8 ft. per mile up from Daguerre Point was reaehed, it would then have stood 36 ft. above the bed of the river. The projected height would thus have been reached, but by building downward rather than upward. Bedrock in the old ehannel of the river is probably at about El. 140, or 55 ft. below the eoncrete apron of the dam.

During 1906, in addition to repairing the damage at the toe and placing the large rock previously mentioned, a spillway 65 ft. wide (150 ft. wide at the entranee) was excavated, and a eonerete side-wall for it, 320 ft. long, founded on solid rock, was built. The spillway and wall foundation required the excavation of 2500 eu. yd. of rock and 8300 eu. yd. of earth. A new railway traek of 25-lb. steel rails, 3-ft. gauge, and nearly level gradient, was constructed from the barrier to the quarry (one-half mile), and ears, derrieks, and an additional hoisting engine, were aequired in order that in future the Government might save the expense of the long haul of eontraetor's plant when a change of contractors oeeurred. The first step of the spillway afforded little relief in floods, but it was capable of earrying the entire dry-weather flow, and was expected to be of service in eonstrueting additional steps to the barrier, as the difficulties in making the closure and turning the water over the completed structure when the first, and to a much less extent, when the second step was built, would be avoided. By the time the work of 1906 had been completed the engineers in charge of the Yuba River work had become convinced that the attempt to increase materially the storage of débris by raising the barrier several additional steps, as planned, would be hazardous to the structure until a spillway of the full capaeity finally eontemplated had been construeted. It may be well to note that the usual risk to interests along a watereourse below a reservoir dam of questionable stability did not exist here, because at no time was

*Paper to be presented to the Amer. Soc. C. E., November 16. Abstracted by permission.

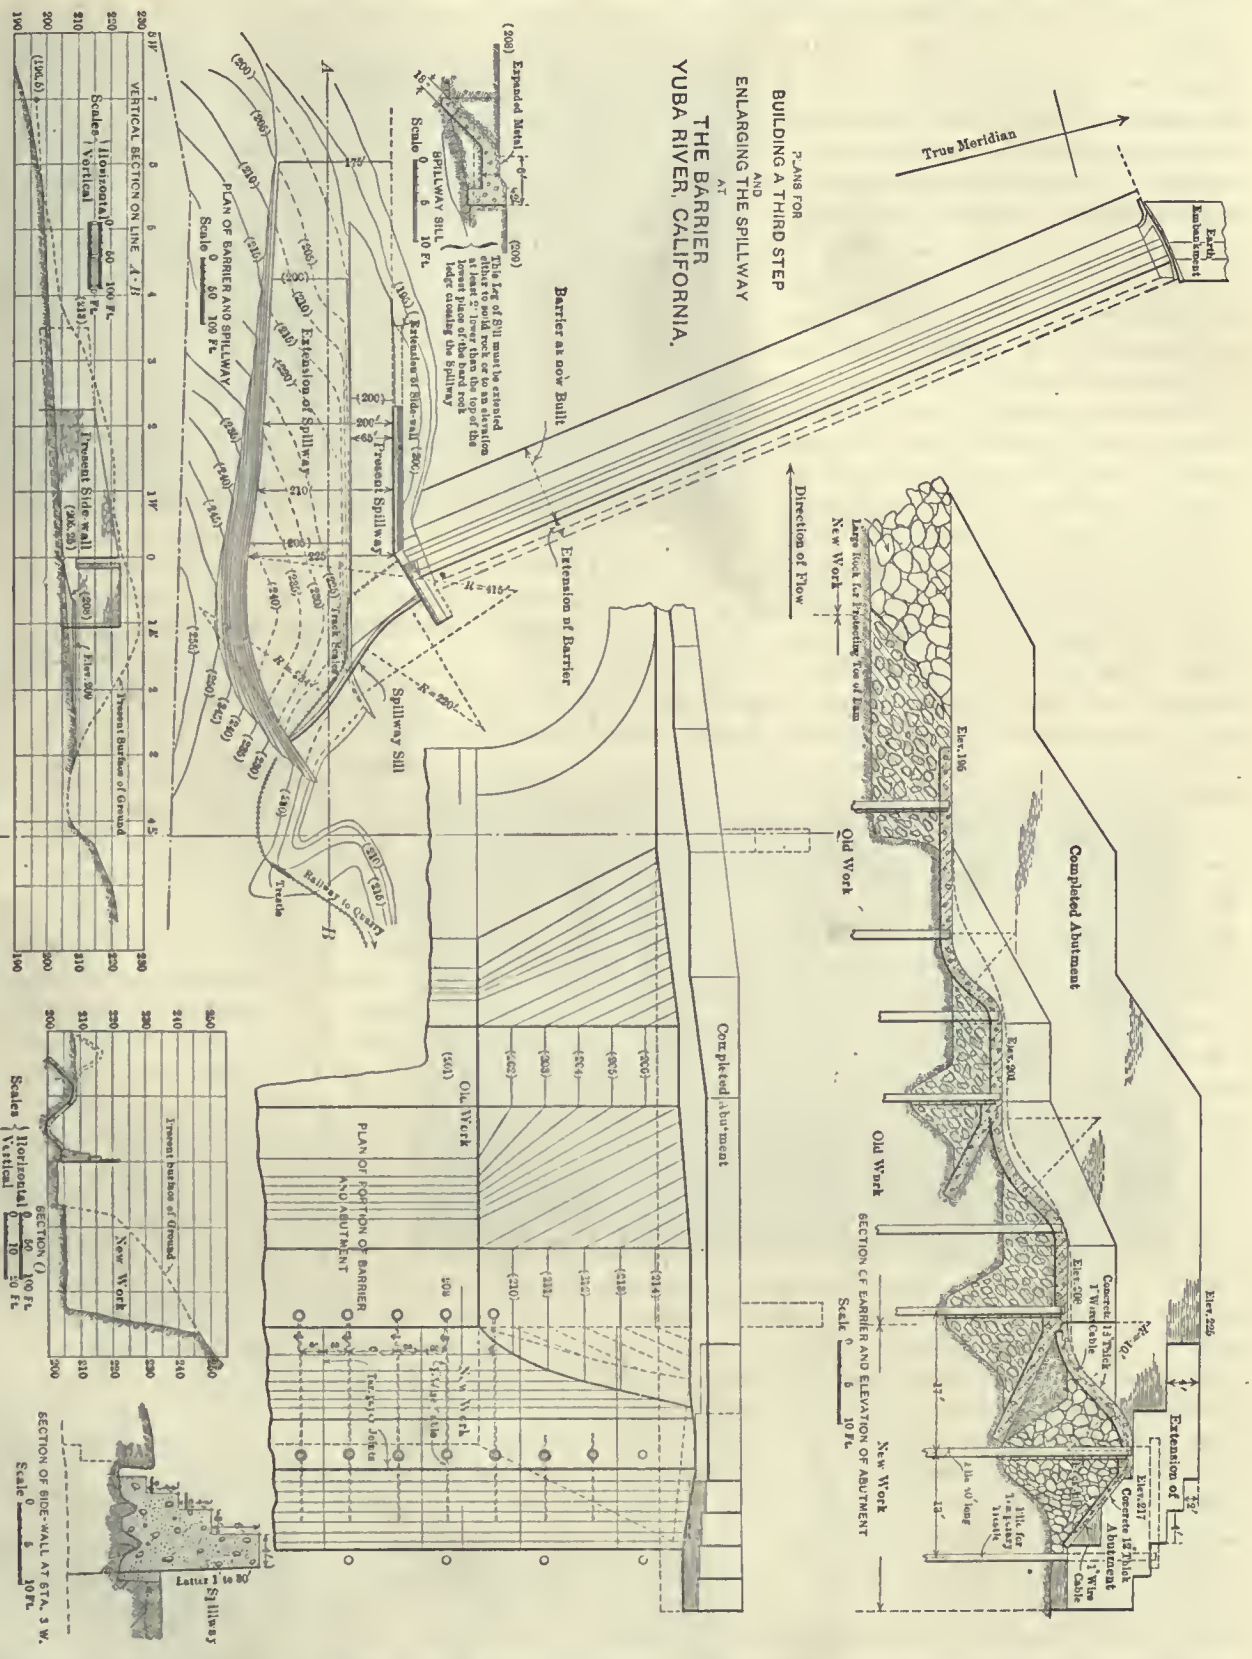

Fig. 1. Plans and Cross-Section.

any considerable volume of water impounded. In designing the several Yuba River works, the maximum flow had been assumed at 125,000 sec.-ft., which was from 25 to 50% greater than the probable maximum, as indicated by available records. This discharge, however, was nearly, if not quite, reached during the 1907 flood. This meant a depth of water of more than 7 ft. over the 1225-ft. crest of the barrier. A flood of anything like this volume, however, continues for but a few hours, and a flow of one-quarter of that amount never continues more than a few days. The site of the spillway was a steep hillside, necessitating a much larger amount of excavation to give a cross-section sufficient to carry the desired flow of 20,000 sec.-ft. below the level of the crest of the barrier than would have been the case could the barrier have been first built to its projected height. As the further movement of large quantities of gravel over the concrete surface of the dam, already backed up to the crest, was then known to be fraught with serious consequences, it was decided to widen the spillway, without materially raising its floor, and to build one additional step to the barrier, which would increase the depth of water in the spillway by its own height and, on account of the large flow through the spillway, would

not be banked up by tailing to its crest, except possibly at its north or farther end. In order that the extensive work contemplated might be done during the season of 1907, plans were prepared and a contract let much earlier in the season than had been customary on previous contracts. On February 23 a contract was awarded for building a third step to the barrier, 8 ft. high, enlarging the spillway, extending both the spillway side-wall and the north abutment, constructing a sill across the spillway, and placing large rock at the toe of the barrier. The general plan for this work is shown in Fig. 1.

Work was started at once. The contractor made arrangements with a water company for water, to be delivered at a point above the site of the work, which would give 100-ft. head; and a plant was partly installed for making the earth excavation of the spillway by hydraulicking. The necessary stripping in the quarry was commenced. From January 31 to February 2 there was a severe storm. The flow of the river, as deduced from depths on the barrier and in the spillway, rose to 80,000 sec.-ft., and a large volume of gravel passed over the dam. The water continued to be too high to permit of a critical examination of the structure, but its appearance, as viewed from either end, did not differ noticeably after this flood from that before. In fact, the rate of scour at the toe seems to have been greater at somewhat lower stages than at maximum flood stage, the reason being that the outlet channel from the pocket eroded from below the toe was of insufficient capacity to carry the flood without backing it up to a considerable extent, thus forming a water cushion. Had this February flood been the last of the season, as might reasonably have been expected, the barrier would probably have been still standing, with but little doubt as to its permanency, as the maintenance would have been a much simpler matter after the completion of the contract then in force. However, the disastrous flood already referred to, which was of greater volume than had ever theretofore been reliably recorded, occurred in that month and during the night of March 17 and 18 about one-half of the barrier was swept away. The contractor's camp was not more than 500 ft. distant, but no one there knew of the failure until the next morning. Water marks in the vicinity showed that before failure the depth on the crest was 7.5 ft. at the south end and 6.5 ft. at the north end. When I examined the place, a few days later, the river-bed through the breach presented the same smooth gravel surface that had marked it before the barrier was started, with only one or two piles, having pieces of the wire-rope anchorage attached, projecting above the surface, about 100 ft. down stream from the line of the dam.

Either of two causes may have been immediately responsible for the failure: first, the undermining of the structure by back-lash; or, second, the wearing away of the concrete surface of the apron and first step, 18 in. thick, thus permitting the rapid washing out of the rubble rock fill. There was not time, nor did the flow of the river diminish enough between the two floods of February and March, to permit of any addition being made to the rock fill at the toe of the dam, or of any repairs to the concrete surface. Considering the conditions at the toe of the dam on the day before the failure, as reported by reliable witnesses, and the appearance of that part of the structure still standing, which adjoined the part washed out, I am convinced that the concrete surface for a considerable length was literally worn away by the great quantity of hard quartz cobbles and gravel which passes over it. Fig. 2, 3, and 4 show the conditions at the barrier at various times before and after the break.

Notes on the design of the spillway may be of interest. The stepped form of the cross-section of the side-wall is due to the fact that it was originally designed with special reference to future enlargement to the requirements of a dam 14 ft. higher than that of the modified plan. The spillway was designed to carry 20,000 sec.-ft. of water before any passed over the barrier. For different depths of water on the crest of the barrier, the total discharge of the river would be distributed approximately as follows:

Depth on barrier.	Discharge over barrier.	Discharge through spillway.	Total discharge.
0	0	20,000	20,000
1	4,400	23,300	27,700
2	13,000	25,700	38,700
3	24,000	29,300	53,300
4	38,000	30,900	68,900
5	54,000	33,400	87,400
6	71,000	36,100	107.100
7	90,000	38,600	128,600

Considering the fact that practically all the scour occurred when the depth on the crest was between 1 and 3 ft., with the spillway completed, the period of scour would be limited to a very few days, even during such a flood season as that of 1907; and it should be remembered that such a record had not been made when the spillway was planned.

The hillside through which the spillway excavation was to be made had a slope of about 1 to 5 and was of irregular formation. The south abutment of the barrier was founded on a ledge of hard blue rock, either trap or diorite. The outcropping rocks on the hillside consisted of boulders and the pinnacles which are characteristic of this region and which, below the surface, vary in character from hard trap to soft chloritic rock or serpentine, and to decomposed rock and clay. When sinking drill-holes in this formation a difference of 2 ft. in position would frequently make a difference of many feet in depth to hard rock, and even then there was no assurance that a ledge had been reached. For this reason the exact location of the sill was left indeterminate. It was to be placed as far up stream as a suitable foundation would permit. The crest of this sill, 2 ft. wide, was to be 8 ft. below the crest of the new step of the barrier. The concrete surface was then to have a drop of 1 ft., on a 45° slope, followed by a 3-ft. level surface. From this point the floor of the spillway was to have a gradient of 1.25%. The plan of the spillway and the gradient were ad-

Fig. 2. Yuba River Barrier, on October 4, 1905.

justed to give the greatest capacity for the least amount of excavation.

In addition to the work for the protection of the barrier, already described, which was in progress, a change in the form of its concrete rollway surface was contemplated in connection with the repairs to that surface which had become necessary. When there had been but one step the water followed smoothly along its ogee shape, but when the second step was constructed the increased velocity at its foot caused it to leap over the upper curve of the first, so that, with its load of gravel, it struck the lower or reverse curve well down toward the apron. The impact of the water and gravel on the concrete doubtless greatly increased the wear on the latter. A uniform slope to the down-stream face would probably have carried the gravel down with less wear, but that form was not adopted originally because less weight was given to that fact than to the reduction in the dangerously high velocities which the steps would effect. To transform the stepped face to a uniform slope would have required an excessive amount of concrete.

A study of the path of the body of water as it leaves the horizontal portion of several succeeding steps, assuming an initial velocity of 8 ft. per second, shows that, if all the energy acquired in each decent were retained, the radii of curvature of the convex portion of each step, from the top down, to be just in contact with the flowing water, would be approximately 2½, 20, and 34 ft., respectively. Assuming that 20% of the energy developed by the fall over each step be dissipated, the horizontal velocity of the water would still be such as to require radii of curvature of 2½, 16, and 25 ft., respectively, for succeeding steps. The destruction of the barrier and the decision to use the further available funds along lines which gave promise of greater efficiency in restraining the movement of débris than would the reconstruction of the barrier, put an end to further consideration of plans for its maintenance. At present, three years after, the site of the barrier presents substantially the same appearance as it did a week after the failure, except that more of the impounded tailing has washed out from the portion left when the barrier failed.

Practically all the monazite of commerce is derived from placer or gravel deposits, all attempts to extract it from its original rock matrix having failed. The deposits were worked like placers—by sluicing and hydraulicking—and the crude monazite sand obtained is further cleaned on concentrating tables and by electromagnetic machinery, which removes its iron content.

Occurrence of Oil and Gas

By William Forstner

The main range and the upper part of the east flank of the Temblor range in the south Midway field, Kern county, California, are covered by a thick, strongly-folded belt of Middle Miocene shales. The lower portion of this belt consists of silicious and clayey shales, the upper third of diatomaceous shales, both intercalated with prominent lenses of coarse sandrock. The underlying Lower Miocene, Vaqueros sandstone, appears only at the surface on the west flank of the range. The oil is believed to have originated in the Middle Miocene diatomaceous shales, and to have migrated partly into the sandstone lenses within the shale, partly into the overlying sands, and probably partly into the underlying Vaqueros. The latter oil horizon in this district lies, however, too deep to be reached.[1] The lower part of the east flank of the range is covered by the McKittrick formation (Upper Miocene-Pliocene-Pleistocene) wherein the commercially available oil horizons of this district are contained. This formation is unconformable with the underlying Middle Miocene shales, dipping less steeply to the northeast. It consists of a series of gravels, clays, shales, and sands. The sands and gravels carry water, oil, tar, and gas, the individual beds and lenses being separated by partings of clay and shale. The water-sands are distributed throughout the formation, and are found at different levels, above, within, between, and below the two oil horizons hereinafter more specially described. They vary in position within the strata in different parts of the field, as does also the composition of the water, which generally speaking is strongly mineralized, especially in the lower strata. Two prominent oil horizons have been differentiated within the McKittrick formation. It must not be understood that these horizons or zones represent continuous strata of oil-bearing sand. They consist of strata of sandstone of varying texture intercalated with shale and clay, and these individual sandstone strata are not persistent but tabular in form. They are not all bitumen bearing, some being barren; occasionally water-sands are found in the oil horizons, especially in the upper zone; others carry oil, gas, or tar. The varying character of the sand in the oil zone is due, partly to the difference in texture, partly to the difference in the general conditions of structure prevailing in the various parts of the field. The zones are limited by more prominent beds of clay and shale.

The Upper Zone (A).—This zone is overlain by a shale belt. It consists of gas, tar, and oil sands, and occasionally some thin beds or lenses of water-sand, interbedded and separated by thicker beds of clay and shale. This zone in the Midway field, except in a part of its southeastern portion, always contains sands carrying oil in commercial quantities, especially toward its base. Underlying Zone A is a belt of blue or brown shale, from 30 to 200 ft. thick, in places containing beds of hard sand, and intercalated water-sands; these shales separate Zone A from the underlying horizon.

The Lower Zone (B).—This is the principal productive zone. It lies at the base of the McKittrick formation, and rests directly on the Middle Miocene shales. Its thickness varies from 10 to 800 ft. In its thicker part there are a number of productive sands intercalated with beds of barren sand, and shale. The sands vary from medium to coarse, with pebbles and cobblestones present. The finer grained

Fig. 1. Temblor Range at Beginning of Upper Miocene.

are generally quartz sands; the pebbles and cobbles are principally derived from granite or other crystalline rocks. In the Sunset field there are, besides, pebbles of diabase, quartzite, and black slate. The composition of these sandstones indicates that at the beginning of the Upper Miocene the crest of the Temblor range was to the west, and at a much higher altitude than at present; and was formed by rocks of Cretaceous and pre-Cretaceous age. This crest was not only eroded during the Upper Miocene and later periods, but must have sunk below the present level of the range, forming northwest-southeast fault lines along the west slope of the present range, thus explaining the surface exposures of the Vaqueros at the present foot of that slope.

The occurrence of heavy shale beds above Zone B, the quartzose sands in Zone A, overlain by another belt of shales, and the foldings in the McKittrick formation indicate strong subsequent oscillations, combined with structural disturbances. The west line of the territory as developed at present in the south part of the Midway field, runs from near the northwest corner of section 36, T. 31-22, in a general southeastern direction through this section, thence through sections 6, 8, 17, 21, 22, 26, and 25 of T. 32-23, and section 31, T. 32-24. Along this line the depth of the top of Zone B below the surface is at the northern end 1600 ft., rapidly decreasing in that section to 800 ft. going southeast, and remaining at this elevation to about section 22, and then gradually increasing until in the southeast corner of section 31, T. 32-24, it is again 1600 ft. below the surface. From this line the top of Zone B, as far as developed, dips to the northeast at an angle of about 16°, while the surface dips only 1° 30′ to 2°, causing the top of Zone B to lie deeper below the surface to the eastward.

The conditions of oil and gas occurrence within this zone, in the western part of the south Midway field can be briefly stated as follows: In sections 7, 8, 9, 16, 17, T. 32-23, the gas pressure is slight; it increases somewhat in sections 14, 15, 21, 22, and 23 of the same township, causing some sand to accompany the oil but not being strong enough

[1] For more detailed description of this field see Bull. 406, U. S. Geol. Surv., from which a number of herein following data have been compiled.

to bring the oil to the surface and make flowing wells; this pressure further increases in sections 24, 25, and 26 of same township, and in the southern part of section 25 the New Richmond well yielded when first drilled sufficient gas to be used. To the southeast in sections 30 and 31 the gas pressure was apparently of no great importance. To the north in section 6, T. 32-23, and in sections 22 and 36, T. 31-22, the wells give evidence of strong initial gas pressures. To the east the initial gas pressure increases considerably, causing the oil to flow over the top of the casing, in many instances with such force as to cause gushers. This elevation of the oil to and above the surface is no doubt due to gas pressure, and not to hydrostatic pressure.

Petroleum is not a homogeneous substance, but a mixture of various hydrocarbons, or series of hydrocarbons. Each of these series consists of a number of hydrocarbons, wherein the ratio of carbon and hydrogen forming the hydrocarbon molecules remains the same, but the number of atoms of carbon and hydrogen forming the molecules is different, such a series being 'polymeric'. The molecules containing the smallest number of atoms of the two elements form volatile hydrocarbons; as the number of atoms increases the hydrocarbons become liquid, and by further increase of that number solids are formed. The series of hydrocarbons which form the petroleum depend upon the conditions under which it was produced; the petroleum of paraffine base consists of a different series of hydrocarbons than those of asphalt base. Within these series the composing hydrocarbons are easily disassociated, forming at one end marsh gas and natural gas: then intermediate fluids, petroleum of various gravities: then viscous and elastic hydrocarbons: and finally solids. The refining of crude oil is based on disassociation by heat or fractional distillation. This same fractionation takes place mechanically to a certain degree when oil passes through fuller's earth, an argillaceous material, which has a great attractive power for greasy substances; water has also the power to further disassociate the petroleum.[2] During the generation of the petroleum by decomposition of organic matter in the shales, different conditions of heat and pressure occur, and even at early stages, gaseous hydrocarbon compounds and petroleum are formed. Water, especially hot oxygenated water, exerts a strong chemical influence on those hydrocarbon compounds, the free oxygen promoting the formation of the lighter hydrocarbons, and restricting the formation of the heavy, tarry hydrocarbons.[3] Bacterial decomposition may also influence the production of those compounds. It has been shown that the volatile hydrocarbons in the oil shales in the upper Mississippi Valley are either directly or indirectly caused by microscopic algea.[4] The formation of these bituminous hydrocarbon mixtures, and their accumulation into globules in the shales, took place through a long geological time, during which disturbances of the strata caused different temperatures in different parts of the shale measures wherein these processes took place; especially when these structural disturbances were caused by irruptive action.

After being formed the hydrocarbon compounds were gradually squeezed out of the fine-grained shales, and migrated into the adjoining more porous sandstone strata. Although shales and clays are generally referred to as impervious, it must be borne in mind that even in the shales the pore spaces average not less than 6 per cent.[5]

The channels through which the gases and liquids move are the interstices between the grains of the rock, and the contacts of the planes of stratification and fracture. The interstices can be subdivided into three classes: (1) openings larger than those of capillary size, supercapillary openings; (2) capillary openings; (3) openings smaller than those of capillary size, subcapillary openings. Supercapillary openings are found in bedding and joint planes, in coarse sandstone, and in conglomerates. In these openings the flow of liquids is controlled by the ordinary laws of hydrokinetics, modified by the viscosity of the fluid, the regularity, size, and length of the opening. Capillary openings include the great majority of interstices between grains of sand and sandstone, many of those in conglomerate, and many of the openings caused by fracture. In these openings the velocity of flow depends upon the area and cross-section of the opening, its length, and the viscosity of the fluid. The movement is so slow that the friction of the moving fluid over the sedentary film is small, especially in long openings. Subcapillary openings include part of the interstices in coarser sediments having capillary openings, and nearly all the interstices between the grains of clays, shales, and slates. The movement of the fluid in these openings is excessively slow; under the hydrostatic pressures generally occurring in those strata the movement will be reduced to such an extent that the fluid may be considered as fixed films held by molecular attraction.[6]

The pressure exercised by the gaseous hydrocarbons probably helped the process of migration of the liquid compounds out of the shales. Gases under high pressure and at high temperature do not adhere strongly to the walls of subcapillary openings, and have small viscosity. Consequently they pass more readily through these openings. The clay and shale derived therefrom always contain water in their subcapillary interstices, entrained therein during their process of formation. The oil originates in the clay beds during the time that the latter are forming at the bottom of the sea, and as a result of the great attraction of oil for clay, the globules of oil, as they form, attach themselves to particles of clay and thus form a petroliferous mud. The migration of the water and oil out of this mud takes place during the compression of the clay which transforms the latter into shale. The overlying sandstones in which the oil and water from the

[6] Mono. 47, U. S. Geol. Surv., pp. 129-146.

shales accumulated, participated in this compression, and the water being less viscous than the oil, the ratio of oil to water was increased in the sandstone. That the oil and gas were not diffused throughout the entire sandstone strata can be explained by assuming that the capillary and subcapillary interstices of the surrounding fine-grained, and partly cemented sandstones anad of the shales, were filled with water, thereby completely sealing up the oil and gas in the more porous portions.[7] Within the porous strata, forming the productive horizons, there are tabular lenses, or possibly strata, of fine-grained and relatively barren sandstone, others of clay and shale, and others of coarser sandstone and conglomerate generally carrying oil and gas, exceptionally carrying water.

As already stated, gases have probably been formed contemporaneously with the oil; volatilization of the liquid hydrocarbons is steadily going on and is especially increased in presence of oxygenated atmospheric water. It must be remarked that water-sands are found only occasionally in the productive oil horizon, Zone B, but are generally found immediately underlying that zone. Natural gas, the gaseous hydrocarbon compound, is a more simple and stable product than petroleum and consequently when it is once formed is not re-converted into oil. In a sealed oil horizon the natural gas will steadily increase, although the rate of increase may be slow. The gas moving with greater ease through the rocks, and being of lighter gravity than the oil, will under ordinary circumstances gather at a higher level than the oil, and where few if any water-sands are present, as is the case in Zone B in the south Midway field. The logical occurrence will be: an upper subzone containing gas, and a lower subzone containing oil. These accumulations will take place in the tabular lenses of coarse sandstone and conglomerate; the bitumen content is less in the finer and more indurated sandstone, and in the finest and hardest sandstone, as in the clay and shale, the amount is generally so small that the rock is considered barren.

In the Midway field this productive zone is at the base of the McKittrick formation, and may be considered to belong to the lower Upper Miocene. During the later geological periods a number of successive subsidences and elevations took place, accompanied by structural displacements, causing folding of the strata, and thereby creating channels along which the fluids and gases could circulate more freely than along the interstices between the grains of the rocks. The clays and shales yielded to the pressures generally by folding; the sandstones more by fracturing. At the present time the top of Zone B is from 800 to 1600 ft. below the surface along the west line of the developed territory; but for a large portion of the time after its formation this zone was buried far deeper than at present. The bitumen was squeezed out of the clays during periods of great pressure, contemporaneous probably with the period wherein these were altered into shales. The greatest pressures were exerted close to the axes of the anticlines and synclines, and here the fissuring of the brittle sandstone increased the conditions favorable to the circulation of the bitumen, but at the same time allowed the access of atmospheric, oxygen-carrying waters, thereby increasing the conditions favorable for the formation of natural gas. Near the axis of an anticline much gas and oil of higher gravity should then be found. The water will because of its weight reach lower levels in the porous strata and accumulate toward the axis of the syncline, leaving the petroleum and the natural gas predominantly above its level. The earth's movements have, however, not been regular, and there is reason to believe that during the long lapse of time from the Upper Miocene to the present, the structure has frequently been changed. In fact the present status is the result of accumulation and dissemination during a great number of centuries under constantly varying conditions.

Within the tabular lenses wherein the oil and gas accumulated the evaporation of the oil continued. If petroleum were a homogeneous liquid this evaporation would continue until the pressure of the gas had reached the vapor pressure at the existing temperature. But, due to the heterogeneous character of petroleum and its tendency to disassociation, I think it is only safe to state that this evaporation continues until a state of equilibrium is reached. This implies that the pressure of the gas is not sufficient to drive the water out of the capillary and subcapillary interstices of the strata surrounding the locus of accumulation. It is impossible to state the pressure required in this case, because according to the formulas of capillary flow the length of the channels and their form are controlling factors, and both are constantly varying throughout any stratum. Assuming a gas pressure of 1000 lb. per sq. in., the largest diameter of capillary openings, with a straight channel through 100 ft. of sand strata, and a temperature of 80° F., the gas pressure would be held in equilibrium by a hydrostatic pressure of 2000 ft., without taking into consideration any friction resistance in the latter column. As the flow of water through capillary openings is greatly reduced by the variation in cross-section of the capillary openings it is readily seen that the sealing of the oil and gas accumulations by the water filling the interstices of the surrounding strata, is complete at a much shallower depth. It may be that in those portions where heavy pressures, from 600 to 1000 lb. per sq. in. exist, the gaseous hydrocarbons have been compressed into liquid form.[8] If this view is correct, the pressures which caused the liquefaction of the natural gas must have been greater than the vapor pressure, and must have occurred subsequent to the formation of that gas. They must have been caused by a compression of the strata which reduced their interstices, probably accompanied with induration of at least part of them by cementation. That such can have occurred during post Middle Miocene times is probable.

The assumption that in the productive oil horizon there are large tabular lenses, wherein the oil accumulates under gas pressures varying in the different

[7] *Economic Geology*, Vol. IV, pp. 517-527.

[8] *Mining and Scientific Press*, June 11, 1910, p. 857.

pools is therefore justified. In each individual pool the material will vary in coarseness and the gas pressure will therefore vary in its different parts. When, because of the completion of a well in such a pool, the oil starts to move therein, the gas pressure will be equalized throughout the pool, and if the well reach the pool in a portion where the gas pressure is lower, it is reasonable to suppose that at the well the pressure may, after a lapse of time, increase; the movement of the oil in the pool toward the wells creating channels through which the gas in the pool can accommodate itself to the tendency of equalization of pressure. That the wells drilled formerly along the west side of the south Midway field showed no gas pressure can be readily explained by the fact that these wells are close to the axis of the Spellacy Hill anticline, and the fissuring of the strata along this axis allowed the gases under high pressure to escape.

Every theory must receive its final test of comparison between deduction and fact. In this case the geologist meets great difficulties in obtaining a sufficient number of facts to thoroughly test the theroy. Many operators will not allow examinations of well logs, and only through the comparison of a number of records can the underground conditions be determined. This secrecy is the more to be regretted as it really acts against the interests of the operator; the better the underground conditions are understood the better the operations can be conducted. A majority of the logs are kept in a manner which prevents a detailed study of the underground conditions and it is rare that samples of the various strata are preserved. These are necessary in order to compare the different strata in the various wells. It is important to test the gravity of the oil, not only at the moment that it is reached in the different oil sands, but also during the period when the well is beginning to flow, until such a time as it has come down to the stage of regular production. This would permit the determination of whether the introduction of the bore in the oil-bearing strata, in case of heavy gas pressures, has affected the internal structure of the strata in such a manner as to allow oil of different gravity, which may be accumulated in the close vicinity, to percolate. In other words, the study of the oil produced, and of the sand it brings to the surface, would give an opportunity to judge the underground changes.

Keeping in mind these restrictions, a short history of the development at the north end of the territory here under consideration may be interesting. This portion of the field covers section 36, T. 31-22, the western part of section 31, T. 31-23, and the extreme northern part of section 6, T. 32-23 (see accompanying sketch). The wells of the American Oilfields Co. along the east line of the S. W. ¼ are situated close to the axis of the Midway anticline. The contact of the McKittrick formation with the underlying shale (Santa Margarita) lies nearly one and a half miles southwest. Considering the steep dip of these shales at that point, this contact would be much deeper below the surface than it is actually found in those wells, so that it is clear that a large portion of the McKittrick has been eroded along this anticline. The steep northern dip of the oil horizon, 800 ft. within one-half mile, finds its counterpart in a northeast-southwest strike having a 50° dip to the northwest, found on the west slope of the anticline in the northwest corner of section 1, T. 32-22, indicating a cross-fracturing of the strata.

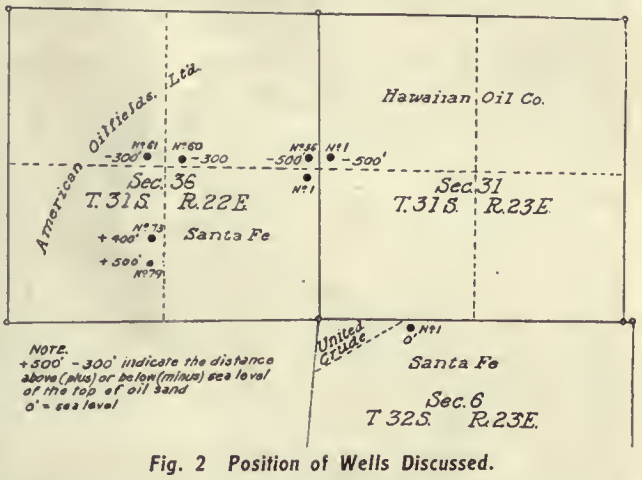

Fig. 2 Position of Wells Discussed.

Along the east line of the S. W. ¼ of section 36 the American Oilfields Co. has several wells. The southern wells have a depth of about 900 ft., increasing toward the centre of the section to 1700. These wells flowed when brought in, giving a good production, the gas pressure causing little or no trouble. The same was true of the wells of the same company along the south line of the N. E. ¼ of same section. The depth of these wells varies from 1700 ft. at the centre of the section to 1800 on its east line. The following official statement of the behavior of well No. 79[1] is instructive: "The well was brought in during May 1910, at 1000 bbl. per day, increasing gradually to 3000 on July 25. From July 26 to August 4, except one day when the well sanded, the flow ranged from 8000 to 10,000 bbl. On August 5 in the morning it flowed at the rate of 20,000 bbl., averaging 15,000 bbl. for the day. August 6, 7, and 8, the average was 16,000 bbl., reaching a maximum of 20,000 bbl. on the morning of August 8. According to advices from the well on August 13 it gave signs of sanding." To this may be added that on the same day No. 79 broke loose, well No. 1 of the Santa Fe in the northeast corner of the S. E. ¼ of same section also broke loose under heavy gas pressure. The elevation of the oil sand in No. 79 is +500, in well No. 56, close to Santa Fe No. 1, it is —500; these last two wells are about one-half mile northeast of No. 79. So far as reported in well No 56, the gas pressure although high, has not reached such a point that the well has got beyond control. The behavior of these wells would in my opinion suggest that when the wells of the American Oilfields Co. reached the oil sands, the gas pressure therein was relatively low, although strong enough to cause the wells to flow; that the movement of the oil toward the outlet, the company having at the time eight producing wells, created channels allowing gas pressure from surrounding territory to reach the producing territory, thereby

[1] *Mining and Scientific Press*, August 20, 1910, p. 248.

inereasing their flow; that the Santa Fe well reaehed a point where the gas was under heavy pressure, possibly occurring in the liquid state, and that the disturbance caused by the sudden gasification of this liquefied gas was sufficient to allow it to reaeh well No. 79. It may be added that American Oilfields Co. No. 73, not very far from No. 79, gave at the time indications of sudden increase of gas pressure.

Hawaiian or Crandall No. 1 in the southwest corner of the N. W. ¼ of seetion 31, T. 31-23, was brought in, May 1909; the top of the oil sand is at —500 ft., 1796 ft. below the surfaee. This well passed several water-sands which gave mueh trouble; it never showed exeessive gas pressure, and the well is now being pumped. It is 600 to 1000 ft. from No. 56 and the Santa Fe well in section 36, and apparently was not influenced by the gas pressure in those wells, consequently it may be assumed that the oil-bearing pools between these wells are separated by an impervious mass.

In the northwest part of section 6, T. 32-23, the Santa Fe brought in a big gusher in November 1909, the elevation of the oil sand being about at sea-level. This well is now being pumped, and has not been influenced by the developments in seetion 36, T. 31-22; the same is the case with the wells of the United Crude in the extreme northwest corner of same section 6. It may therefore be assumed that there is also an impervious barrier between the oil pools from which these wells derive their oil and those in section 36. It must not be eoncluded, however, that these impervious masses indieate intervening barren areas, as it is possible that in those areas oil-bearing lenses may exist, at a higher or lower level, in the producing zone.

Arsenic and Antimony.—These constituents are volatilized to a large extent in pyrite or semi-pyrite smelting. They may be almost entirely eliminated in reeoneentrating the matte.

Force Account Costs

For many years it has been eonsidered that economical engineering work could be done by contract only. Reeently there has been a disposition to do more work under direct supervision of the engineers in charge of any construction. Around the mines this is usually referred to as 'working on company aeeount.' In eivil engineering such work is spoken of as being done on 'foree aeeount.' The U. S. Reclamation Serviee, under F. H. Newell, director, and A. P. Davis, ehief engineer, has had perhaps more experience with force account work than any other large organization. The following figures, taken from their books, make an excellent showing for this method of work.

COMPARATIVE TABLE OF COST

	Force account.	Estimated cost if lowest bid had been accepted.	Estimated saving in cost.
Upper Deer Flat embankment	$279,820.83	$396,522.19	$116,701.36
Belle Fourche tunnel	33,230.29	92,592.54	59,362.25

Dry-Placer Machines

By Glenn M. Peterson

In Arizona, Lower California, and northern Mexico, there are large areas of gravel that have been worked for nearly a hundred years in a crude way with hand dry-washers, and several million dollars are said to have been recovered by this method. The miners could work only the rich ground and had to have favorable conditions in order to save the gold. One of the principal reasons for so many failures heretofore is, that in nearly all of these dry placers the gravel is cemented with carbonate of lime and in some places to such an extent as to form large beds of cement or conglomerate.

A little over a year ago, Mitt Quinner built at Nogales, Arizona, a machine to pulverize gravel, which embodies some new features as an ore crusher and pulverizer. It has been working ever since at Boluda, in the Altar district of Sonora, Mexico. It consists of a drum 40 in. diam. by 6 ft. long, which revolves on trunnions at 20 r.p.m. with a shaft 4 in. diam. in the centre, which revolves at 400 to 800 r.p.m., in the same direction as the drum. On this shaft there are clamped 36 chains, on the ends of which are fastened 8-lb. hammers; these are square, but are set so as to present an angle to the material, and are made of cast manganese steel. These hammers, though rigid when in motion, are still flexible, and at 400 revolutions per minute have a striking force of 1800 lb. The drum is made of two boiler heads, to which are bolted steel flanges that run on the trunnions. On the outer rim of the boiler heads, to form the sides of the drum, are bolted flat steel bars 1½ by 2 in. by 6 ft. long, which are spaced according to the desired fineness of the material to be ground—usually ⅛ in. apart. At the head of this drum or trommel, there is a 24-in. circular opening through which the mill is fed. At the discharge end there is a 28-in. round opening, which is protected with an adjustable shield so as to regulate the discharge of the oversize. The mill weighs 3 tons, occupies a floor space of 5½ by 15 ft., and requires 20 hp. to operate. In placer work it is adjusted to crush the softer cemented material to 8-mesh. About 50% of the material fed to the mill passes through the space of the bars, the remainder being discharged automatically as oversize. All the gold passes out with the fine screenings, except large nuggets, which are retained in the drum.

About sixteen years ago, Albert H. Stebbins began his experiments in the endeavor to find some means of separating the fine as well as the coarse gold from gravel and other materials, by a dry process at a low operating cost. He made experiments in different dry-placer fields. During this time he built and tried many machines and processes and finally perfected a table with a perforated metallic surface admitting a current of air over the entire table, at a low angle to it, thereby forming a thin film or cushion of air into which all the fine as well as the coarse gold dropped, to be collected in the riffles; the lighter materials passing along over this continuous air-space. With the use of this perforated surface, he has been able to construct a dry concentrating table that will make a high extraction and will save fine gold. The table has a reciprocating and progressive movement, with a throw of ¼ in. and 300 vibrations per minute.

Since perfecting this dry concentrator, Mr. Stebbins has spent nearly three years in trying it under varying conditions, and has found that the metallic surface never gets out of order, never clogs up, and can always be depended upon to work well. This table is built in sizes that have an actual working capacity of from 5 to 40 cu. yd. per hour. It requires 2 hp. to operate a 5-cu. yd. table, with one additional horse-power to each additional 5 cu. yd. per hour in capacity. When the gold is liberated and freed in the gravel by the pulverizer, these dry tables will make as high an extraction as with Hungarian riffles, and will save as much flour gold as can be saved with cocoa matting. In mining the ground with a steam-shovel, the material is delivered in a large hopper, from which it goes to a coarse trommel (bars spaced about 5 in.) that rejects all large stones; the material passing through the grizzly goes to a hopper beneath which feeds the Quinner pulverizers, which crush, pulverize, and screen the material, discharging about 50% as screening containing all the gold. The balance, as oversize, is discharged from the rear end of the mill onto a belt-conveyor that leads to the stacker. The screening falls through a hopper on a belt-conveyor that discharges into the hopper bins, which feed directly on the dry-placer tables. The tailing from these dry concentrators discharges on a belt-conveyor that carries it to the main stacker.

Mattes and Concentration Ratios.—It is not often desirable to use a matte of less than 5% copper, for efficient collection of values. In cases where copper is lacking to bring the matte up to this standard, it would be advisable to re-charge enough roasted matte to supply this, providing the additional saving paid for the cost of the operations. The copper in the matte should be proportional to the matte fall. With high concentration, 10% copper, with low concentration 2 to 3% copper is sufficient. The grade of the matte should also vary directly with the amount of gold and silver and impurities present. In general, it is not good practice to use high concentration ratios such as 18 to 22 tons of charge into 1 ton of matte, except where conditions demand this or with exceptionally pure ores in furnaces of 200 or more tons capacity. A 10 into 1 or 12 into 1 concentration is about the most satisfactory limit. For example in a furnace 36 by 84 inches, making a slag assaying SiO_2 34%, FeO 33, CaO 20, concentration of 10 into 1 caused the furnace to crust badly and often necessitated refeeding of matte. A 15% matte fall proved more satisfactory.

A millsite can only be taken on unappropriated non-mineral land. It is not necessary to own a mine in connection with the millsite, as a custom mill or smelter may be built on such land.

Sixty Years of Rainfall in California

By Alexander G. McAdie

*The accompanying diagrams of seasonal rainfall first came into prominence during a period of drought, the dry seasons of 1897-8, and 1898-9, when there was widespread uneasiness among the people and a general misapprehension that the climate was permanently changing. The charts conclusively show that such dry periods are only incidental and give no true indication of a permanent change. Indeed, it was made plain that there was every reason for expecting a return to normal conditions.

It is not yet possible to forecast with any degree of certainty the coming season; but the careful student can detect in these records certain seasonal trends. He can also more intelligently refute the hasty conclusions put forth now and again by eager but poorly informed persons who think they have found the secret of seasonal forecasting.

It is plain that there is no regular sequence of wet and dry seasons, and this is as it should be, because while law is supreme in meteorology as elsewhere, and the storms develop, move, and disappear in accordance with physical laws understood in part, there are too many independent variables entering into the problem of rain formation and the condensation of the water vapor of the air to allow much hope for a regular and easy solution of the problem. It is plain from the charts that an abnormal wet month is not necessarily followed by another of the same character; or in other words, rainy periods are of unequal length. No one can predict from the existence of one dry month in winter that the balance of the season will be dry. All that can be said at present is that wet seasons and dry seasons come and go in a very irregular way. Nor is there any determinable period between abnormal conditions. The chart herewith covers the rainfall for sixty years at two stations, San Francisco and San Diego, more than 500 miles apart. If the sixty years be divided into decades, the following averages appear.

SAN FRANCISCO

	Inches.
10 seasons, 1849-59	227.47
10 seasons, 1859-69	257.85
10 seasons, 1869-79	227.00
10 seasons, 1879-89	234.23
10 seasons, 1889-99	218.81
10 seasons, 1899-09	210.28

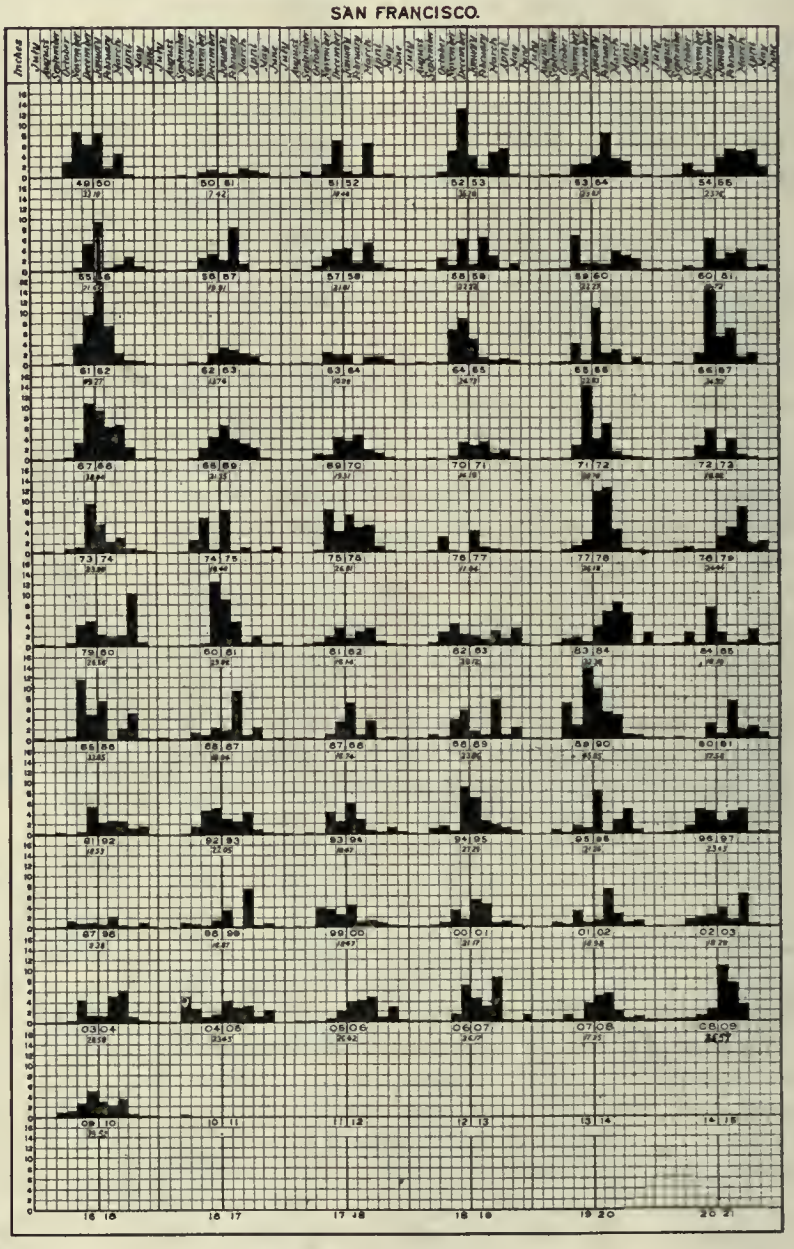
*Abstracted from *The Pacific Rural Press.*

The mean rainfall for six decades is 229 inches.

It is interesting to note that during the month of January 1862, 24.36 inches fell; more rain fell in one month than the normal annual rainfall.

SAN DIEGO

	Inches.
9½ seasons, 1850-59	81.05
10 seasons, 1859-69	97.04
10 seasons, 1869-79	84.71
10 seasons, 1879-89	119.21
10 seasons, 1889-99	88.54
10 seasons, 1899-09	97.24



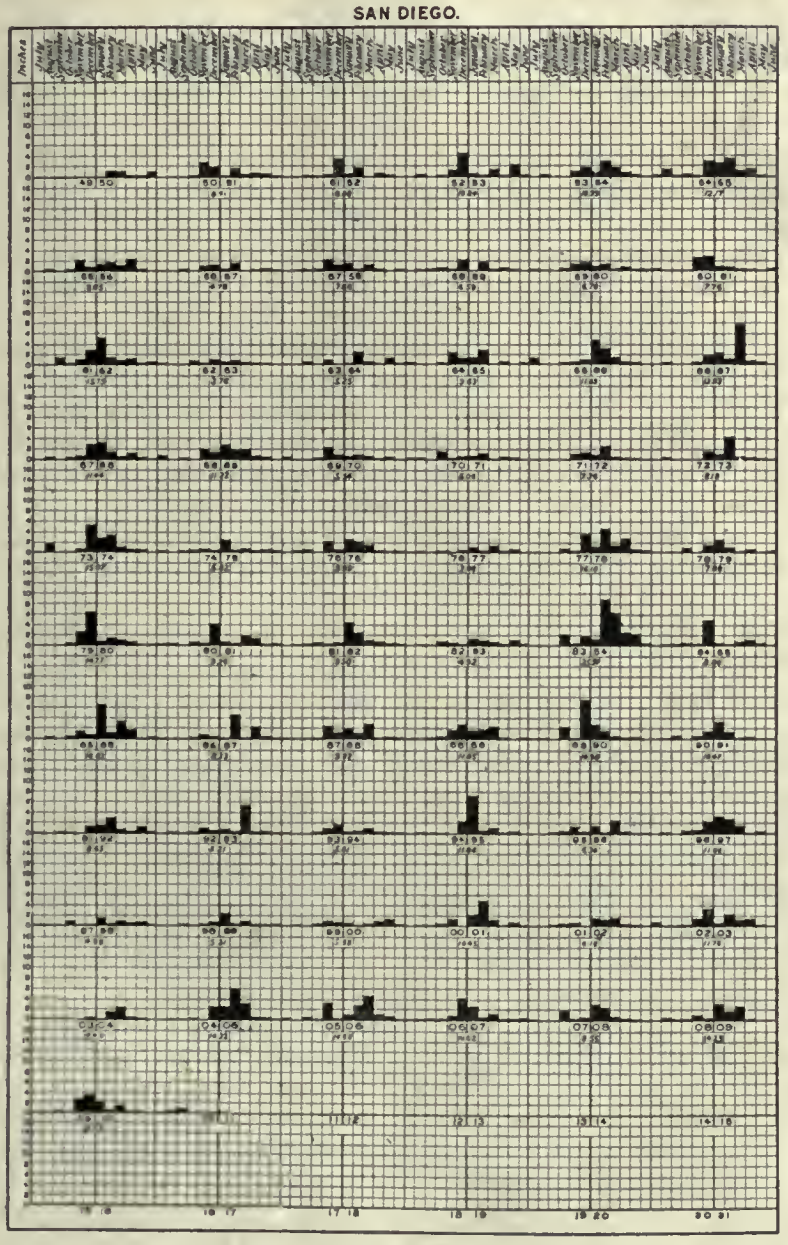
Rainfall Records at San Francisco.

Allowing for the missing half season, the average rainfall for each ten seasons becomes 95 inches. Note that in February, 1884, there was a rainfall of 9.05 inches; or almost as much as the normal rainfall of an entire season.

The statement will often be heard, especially in southern California, that a dry October presages a dry winter, but the records show that little dependence can be placed in statements of this character. One of the heaviest seasonal rainfalls, that of 1873-4, followed a dry October. A wet fall is, however, frequently followed by a wet winter.

Also be it remembered that the State of California

extends from latitude 32° 40′ to 42° 0′ N. It has a mean length of nearly 800 miles, with an average width of 200 miles and an estimated area of a hundred million acres. Naturally in so large an area there must be great diversity in the character of the rain. At some localities in the State the seasonal rainfall does not average one inch, while at others it exceeds 80 inches. In general, seasons of heavy rainfall in the north are also seasons of good rainfall in the south. But exceptions can be found even



Rainfall Records at San Diego.

to this. There is one type of storm, the Sonora, which, causing heavy rains in the south, leaves the northern counties practically without rain. On the other hand, many of the northern storms pass eastward without resulting rains in the southern counties.

Pyritic ore is not used for fuel in Colorado or elsewhere, except in smelting sulphide ore by what is known as 'pyrite smelting,' in which little or no carbonaceous fuel is added to the furnace charge. In practice it is found better to add coke and depend less on the sulphur.

COAL RESOURCES OF TEXAS

William B. Phillips, director of the bureau of economic geology of the University of Texas, has issued an interesting statement of the coal resources of the State, in which he says:

Since the year 1884 the production of coal and lignite in Texas has been 18,199,584 tons. The separation of these two items in statistical reports was begun in 1895. Since that time the production of coal has been 10,767,866 tons, valued at $22,596,544, about $2.10 per ton at the mines. During the same period the production of lignite has been 5,488,218 tons, valued at $4,767,830, or an average of 82.8c. per ton at the mines. During these 15 years the production of coal has increased so that for each ton mined in 1895 there were 3.17 tons mined in 1909. In the year 1895 the average value of the coal mined was $2.22, and in 1909, $2.37. The production of lignite increased much more rapidly than that of coal. For each ton of lignite mined in 1895 there were mined 4.75 tons in 1909, the value per ton for the respective years being 90 and 82.8c. The latest estimates of the original supply of bituminous coal in Texas show that there were 8,000,000,000 tons, and of lignite 23,000,000,000 tons, or a total fuel supply of 31,000,000,000 tons. If each ton of fuel mined represents a loss of 1½ tons the loss of coal and lignite thus far is 27,299,376 tons, an insignificant proportion of the original supply. During the last 26 years the loss of fuel has been so small, compared with the original supply, as to be negligible in any estimates affecting the situation. The workable coal area may be taken as 8200 sq. mi., with an additional area of 5300 that may contain workable seams. There is much uncertainty in regard to the workable lignite area. The estimate of M. R. Campbell, of the United States Geological Survey, shows 2000 sq. mi., but it is probably much nearer 20,000. For the additional lignite area he gives 53,000 sq. mi., or a total of 55,000. The total workable area of coal and lignite has been taken as 10,200 sq. mi., with an additional area of 58,300 that may prove to be workable.

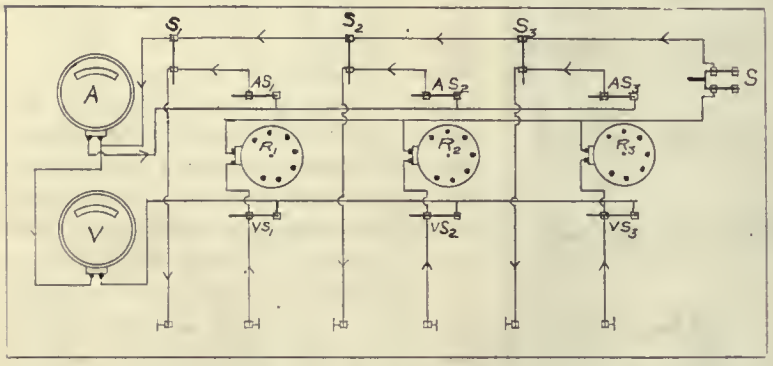
Leading copper selling interests state that there is still considerable copper to be bought by domestic consumers for the last two months of the current year, notwithstanding the record-breaking sales of the past few weeks. The statement that foreign purchases have been largely responsible for the large recent transactions still holds, with the American manufacturers at the 'tail end of the cart' picking up odd lots for the most part.

Electrolytic Determination of Lead in Ores

By R. C. Benner and W. H. Ross

The determination of lead in ores by the electrolytic method has been much used during the past few years in many parts of the West. In this determination the lead is deposited as the peroxide on the anode and has to be weighed as such. This compound of lead, when deposited electrolytically under the ordinary conditions used by chemists, varies slightly in composition, so that a different factor, which has in but one case been the one called for by theory, gives the correct result when used.

[When the peroxide has been deposited on a dish it is possible to ignite and weigh as the monoxide with excellent results,[1] but with the gauze electrode, which has been used in this piece of work, it is impossible to make the ignition over the bunsen flame in a satisfactory manner. Sand[2] has been able to deposit the peroxide in such a condition that the error caused by the use of the theoretical factor is negligible. This was accomplished by depositing the peroxide from a solution free from the oxides of nitrogen and ammonium nitrate, at a temperature of from 94 to 97°C., using a current of five amperes. When the deposition was performed under these conditions he used the factor 0.8651 after drying the deposit with alcohol and ether.



When making use of the gauze electrode designed by one of us[3] for the rapid precipitation of lead, it is necessary, as well as convenient, to have a switchboard system which will enable one to connect the electrodes and take ammeter and voltmeter readings quickly and conveniently. The apparatus shown in the accompanying illustration has been used by us for this purpose and has proved satisfactory. Each electrolytic cell is independent and the number which may be connected up in the series is limited only by the current available. Connections are shown in the illustration for three cells.

The three cells are joined in parallel, and one or more may be operated at the same time by means of the single-pole single-throw switches S_1 to S_3. Unless an ammeter or voltmeter reading is desired the switches AS_1 to AS_3 and VS_1 to VS_3, which connect with the ammeter and voltmeter respectively, are left open. The current flowing through Cell C_1, for example, will pass from switch S in the direction indicated by the arrows, through switch S_1, which is closed, to cell C_1, then through resistance R_1, and finally to the switch S. When it is desired to know the current flowing through any particular cell as C_1, the switch AS_1 is closed and S_1 opened. The current will then flow through the ammeter A, to the switch AS_1 and through C_1 and R_1 as before. In the same way the current flowing through any other cell is found by closing and opening the corresponding switches with which it is connected. The voltmeter is so arranged that it may be joined in as a shunt on any of the parallel circuits through which the current passes in going through the different cells. Thus, if the voltage of cell C_1 is desired, switch VS_1, current passing through cell C_1 will pass by way of switch S_1, but a small fraction is closed, the other two voltmeter switches being left open. The greater part of the of the current will separate at S_1 and pass through the voltmeter in the direction indicated by the arrows. In the same way the voltage of any of the other cells may be found by closing its voltmeter switch for an instant. When taking a voltmeter reading of any cell as C_1 it is immaterial whether switch S_1, AS_1, or both are closed. Each of the cells C_1 to C_3 has a resistance R_1 to R_3 joined in with it, so that the current flowing through any particular cell may be regulated at will. Each resistance should have such a range as would be sufficient to vary the current within the limits desired. The system as thus described should be set up in switchboard form. The connecting wires may then be placed at the back of the board, making a simple and compact piece of apparatus. The terminals represented in the sketch should be made of aluminum so as to avoid contamination of the electrolyte with copper as is likely to be the case when the ordinary form of terminal is used.

A lead nitrate solution containing 0.2508 gram of lead in 10 c.c. was prepared, in order that experiments might be made with the gauze electrode, and the accuracy of this method proved when stationary electrodes were used. The following determinations were made in 75 c.c. of solution, in the presence of 10 c.c. of nitric acid (sp. gr. 1.40) with a current of 4.8 amperes and 2.5 volts. The electrolyte was warmed during the deposition, so that the temperature of the cell was kept just below the boiling point; the highest temperature at which it is possible to carry on the electrolysis without liberation of the oxides of nitrogen, which, according to Sand, tends to make the deposit non-adherent.

The results given above verify those obtained by Sand and give an idea of the accuracy of the method. The rate of precipitation was determined with a current of 3.5 volts and 4.2 amperes at a temperature between 94 and 97°C. The solution in each case contained 0.5018 gram of lead and 10 c.c. of concentrated nitric acid and had a volume of 75 cubic centimetres.

RATE OF PRECIPITATION

Time, min.	Lead taken.	Lead deposited. Factor 0.866.	Peroxide deposited.
1	0.5008	0.2412	0.2789
2	0.5008	0.4126	0.4766
3	0.5008	0.4536	0.5237
4½.....	0.5008	0.4871	0.5623
5	0.5008	0.5012	0.5787
11	0.5009	0.5007	0.5782

These results show that it is possible to deposit all of the lead in a 0.5 gram sample of ore in from 5 to 10 minutes. In this case, as with copper, by far the greater part of the lead was deposited in the first 3 minutes, while the remaining 10% took 3 minutes longer.

A short process is possible for some classes of ores, because all of the sulphur from galena as well as from some other sulphides can be removed in form of hydrogen sulphide, by warming with hydrochloric acid (2 to 1). This makes it possible to use the following process for ores which contain no interfering sulphides. From 0.5 to 1.0 gram of the finely powdered ore is weighed out, warmed with 15 to 20 c.c. of hydrochloric acid (2 to 1) until completely disintegrated and all of the sulphur evolved as hydrogen sulphide, but not concentrated so far that the lead chloride crystallizes out (this causes violent bumping). Then 20 c.c. of concentrated nitric acid is added and boiling continued until all of the hydrochloric acid is expelled and the nitric acid has a volume of 10 c.c. It is then diluted to 75 c.c. and electrolyzed in the usual manner. The ores containing sulphides which render the use of the preceding method impossible, may be disintegrated with nitric and hydrochloric acids, 15 c.c. of sulphuric acid being then added and the solution evaporated until white fumes of sulphuric anhydride are evolved. After cooling, 50 c.c. of water is added; the solution boiled until all of the basic sulphate of iron is dissolved, then diluted to 200 c.c., filtered, and washed free from sulphuric acid. As much as possible of the lead sulphate should be left in the beaker and washed by decantation. The lead sulphate is washed from the filter into the beaker containing the bulk of the sulphate with the smallest possible amount of water. Then 10 c.c. of a warm saturated solution of ammonium carbonate is poured through the filter, received in the beaker containing the lead sulphate and warmed until all of the sulphate is converted to the carbonate. The lead carbonate is then filtered through the same filter, washed with water until nearly free from ammonium carbonate, dissolved in 40 c.c. of nitric acid (1 to 3), the filter paper washed free from lead, and the solution electrolyzed in the usual way. The following results on a lead ore containing copper will show the accuracy of the method. Analysis of the ore by ordinary methods showed that ore No. 1 contained 2.70% copper, 21.50 lead; ore No. 2, 2.28 copper, 22.20 lead. By the electrolytic method ore No. 1 was found to contain 21.52, 21.51, 21.59%, and ore No. 2, 22.06, 22.20.

Where it is desired to do away with the factor, and at the same time use the electrolytic determination, it is possible to do so by heating the gauze electrode on which the peroxide has been deposited in a muffle, or small electric oven at a temperature of about 500°C. The following results show the accuracy of this modification of the electrolytic method.

Lead taken.	Lead found. Factor 0.866.
0.2509	0.2511
0.2509	0.2506
0.5018	0.5025
0.5018	0.5026
0.7527	0.7518

COPPER-MINING INDUSTRY OF RUSSIA

By John H. Grout

*During various periods in history the territories now forming the Russian empire have been alternately exporting and importing copper and copper ware, but during the nineteenth century Russia became an ever-increasing market for copper of foreign production.

About the beginning of the present century, when there was everywhere a great demand for copper and it became the object of acute speculation, attention was directed to entire groups of Russian mines inadequately worked or fully abandoned, and, with the aid of cheap foreign capital and foreign engineers, the mines were energetically taken in hand. As a result, the table which follows shows how Russia is now fast becoming a self-supporting country in the matter of copper, and that the date cannot be far off when it will have to look for outlets in the world's markets for its surplus production of copper. From far away districts in Asia, especially where there are no properly arranged and convenient trade routes, the cost of transportation, from 25 to 51½c. per pood (36.2 lb.), will greatly impede this, but copper from Caucasia, about one-third of the total production, may well be devoted free for the world's markets. It must be kept in mind, however, that the growing population of Russia, with its demands, will remain an increasing consumer of the country's copper. From estimates recently made, Russia will consume 24,768, 27,054, and 29,538 tons in 1910, 1911, and 1912, but still the output is expected to grow more rapidly than that, as may be judged by the following table.

Year	Production, tons.	Importation, tons.	Consumption, tons.
1901.....	9,306	12,348	21,654
1902.....	10,404	19,584	29,988
1903.....	10,152	16,182	26,334
1904.....	10,800	21,078	33,878
1905.....	10,800	21,078	31,878
1906.....	11,340	14,760	26,100
1907.....	16,218	4,896	21,114
1908.....	18,558	4,860	23,418
1909.....	20,106	3,834	23,940
